The complicated cases show clearly the importance of thorough treatment of the prostate, the cases of prostatitis requiring, on an average, ten days longer than those of arthritis, and twenty-two days longer than those of epididymitis. The longest cases of all were those in which acute prostatitis was followed by acute epididymitis, this group forming 3 per cent. of the total. The average stay of all complicated cases was fifty-two days, or several days under two months.

It has from time to time been suggested, though never with adequate proof, that vaccines are dangerous in the acute stage, and lead to complications. If this were so it would have been expected that in this series of 500 acute cases, all treated from the start with big doses, a large proportion of complications would have developed, especially epididymitis and arthritis. This is not the case.

Of the 101 epididymitis cases 70 were present on admission, leaving 31 developed out of 430 cases, that is, 7 per cent.

Of the 10 arthritis cases 8 were present on admission, leaving 2 developed out of 490 cases, that is, less than 1 per cent.

The most remarkable feature of all is the exceptionally low percentage of relapses. Out of the 500 cases two only

have occurred during a period of four months after completion of the series. Many of the cases left hospital more than six months ago. This gives a relapse rate of less than 1 per cent. It is a very satisfactory proof of the value of vaccines as a test of cure, and although by omitting it the number of days under treatment could be reduced in many instances, the relapse rate would very soon counter-balance any gain. At the present time everything possible has to be done to minimize the number of relapses of gonorrhoea cases, and this system has been found, in actual practice, to be far in advance of any other; whilst the number of days under treatment compares favourably with any known figures.

TABLE II.—Results of 500 Consecutive Cases treated with Vaccines in the Acute Stage.

Number of uncomplicated cases	...	278
Number of complicated cases...	...	222
Average number of days in hospital (all cases)	...	43
<i>Uncomplicated cases 278, made up as follows:</i>		
Under treatment 30 days or less	...	157*
(Average 19 days)		
Under treatment 31 days or more	...	121
(Average 55 days)		
<i>Complicated cases 222, made up as follows:</i>		
Epididymitis	...	101
(Average 38 days)		
Prostatitis	...	94
(Average 60 days)		
Arthritis	...	10
(Average 50 days)		
Acute prostatitis and epididymitis	...	17
(Average 86 days)		
Average stay of all uncomplicated cases	...	35 days
Average stay of all complicated cases	...	52 days
Number of cases relapsing (four to six months after completion of treatment)	...	2†

* That is, 60 per cent. discharged with an average of 19 days.

† That is, less than 1 per cent.

A NOTE ON THE ELECTRO-CHEMICAL TREATMENT OF GONORRHOEA.

This form of treatment seemed to offer some hope of success, and since it has recently been brought into prominence by one or two writers, it may be of interest to record the results obtained.

The method adopted was similar to that of Russ, with the additional advantage that provision was made for distending the urethra with fluid during the passage of the current. This gave all the advantages of dilatation, together with the exposure of a larger surface to the electro-chemical action and increased hyperaemia. A perforated straight silver catheter was used, the top being closed by a small rubber cork through which a hollow silver stylet passed, reaching down to the bottom of the catheter. A small side tube also entered the catheter, so that fluids could be run in, whilst a small ring of rubber tubing round the stem, six inches from the tip, served to make a water-tight joint when the instrument was in position. A glass container and four feet of india-rubber tubing held the chemical solution, which could be run in through the side tube and out again at the top of the hollow stylet. Thus, by closing the exit from the hollow stylet, fluid could be run into the catheter under pressure, dilating the urethra and giving the advantages mentioned. The pressure was regulated by raising or lowering the glass container. Sodium iodide with dissolved iodine (5th per cent.) was used, the positive pole being connected up to the stylet within the catheter and a current of 3 milli-amperes passed for ten minutes and then reversed for a similar period.

Of twenty acute cases so treated one only, a mild case, was cured. In this instance twelve applications were given and no other treatment. In the remainder the discharge soon diminished, but the urine did not become entirely clear, and after three weeks' treatment vaccines were used. One of the twenty, a severe case, was practically unaffected after twelve applications. In others various solutions and current strengths were adopted, but with no more definite results. Undoubtedly this treatment has a beneficial influence on the urethritis in the acute stage, the discharge and soreness diminishing, but in my own cases there was nothing to show that it could be considered curative.

THE American Red Cross has sent a group of specialists in infant welfare to France. At its head is Dr. William P. Lucas, Professor of Paediatrics in the University of California. The mission will study the work already being done by the French, and will practise without fees. Its work is to co-operate with French specialists and carry on an educational campaign among French mothers with the object of securing better prenatal hygiene and scientific feeding and care of babies. Special efforts will be made to protect children from tuberculous infection.

A CASE OF GONORRHOEAL KERATOSIS.

BY

CAPTAIN W. H. BROWN, R.A.M.C.(T.C.),

AND

CAPTAIN A. M. DAVIDSON, R.A.M.C.(T.C.).

CONSIDERING the prevalence of gonorrhoea, we may say that gonorrhoeal keratosis is very rare. This case is the sixth recorded in our country, and consequently deserves to be brought to notice.

The patient is aged 25, a regular soldier, of seven years' service. He contracted gonorrhoea early in 1914 and was treated at Curragh Hospital with irrigations. After four months' treatment he was back on duty and well by July, 1914. He came to France in October, 1914, and remained perfectly well till May, 1915. He exposed himself to infection again, and was admitted to hospital on the fifth day of his second attack, May 18th, 1916. On admission he was sharply ill—temperature 102° F., acute gonorrhoeal arthritis of the right ankle and great toe, muco-purulent urethral discharge. The prostate was hard and the right lobe nodular, suggesting chronic prostatic trouble. Both seminal vesicles were also indurated and readily palpated. Four days after admission the right wrist became acutely painful and swollen, and nine days after admission there developed acute arthritis of the left knee, which within thirty-six hours had to be tapped. Over 100 c.cm. of thick serous fluid was withdrawn; no gonococci were found in the fluid, but pus cells were present. Patient was treated with urethral irrigations and vaccines—mixed gonococcus and staphylococcus. Local treatment to joints consisted of radiant heat and massage, and at the end of ten weeks he was sent to a convalescent home well.

Skin Condition.

Three days after admission peculiar small nodules were noticed on the right foot, which was greatly swollen, and as the patient's general condition was very bad, and he was anaemic, it was thought he was developing septic lesions of the skin with cellulitis. Under treatment the swelling of the foot and ankle subsided, but the skin lesions gradually became more numerous and extended to the left foot. In ten days the lesions had become quite distinct. They were hard and shotty, and when pricked with a needle were found to be solid. The accompanying photographs show the appearance and distribution of the eruption twenty days after admission. As the case was under observation from beginning to end, all the various phases could be traced, from the smallest lesion noticed to those fully developed. The small group of lesions shown in Fig. 2 on the dorsum of the right foot appeared three weeks after admission. Briefly, the eruption was discrete, and consisted of very small conical nodules or crusts, very hard, and varying in size from that of a large pin-head to that of a pea. The smallest lesions were more or less conical in shape, with a firm, horny feel, and giving the impression of being just under the epidermis, which remained intact over the small cone and normal in colour. From this stage to that of the largest there were all grades.

As the lesions increased in size the epidermis became whitish over the cone, and gradually gave way at the apex, exposing a small hard brownish crust, in colour and consistence very like beeswax. When the epidermis had completely given way a loose fringe of epithelium encircled the underlying hard cone, and the cone itself could be easily picked out from the underlying Malpighian layer, leaving a smooth pinkish area on which the base of the crust had been attached. The striking

way in which these hard cones could be picked out, even in the very earliest lesion, by artificially breaking through the covering epithelium, left no doubt that they developed between the Malpighian layer of the skin and the corneal layer. There was no bleeding on artificially removing these crusts. In the larger lesions, where the covering layer of epidermis had practically disappeared, these crusts looked as if they had been simply cemented on to the skin. Excepting a few of the largest lesions, where the crusts were disc-like—three-eighths of an inch in diameter and about one-eighth of an inch thick—they were all fairly uniform, conical, with a flat base. Some were perfectly limpet-shaped, with a concave base resting on a convex elevated surface. All the crusts were hard and dark brown in colour.

The parts affected were chiefly the soles and borders of the feet. A small group of lesions is seen on the dorsum of the right foot; some lesions were present on the dorsal and plantar surfaces of the toes; there were none on the hands or any other

part of the body. As the patient improved the crusts gradually fell off, and the skin returned to its normal condition. Cultures were taken from under the crust but no growth resulted. No initial erythema or telangiectasis was observed, as described by Williams in his case, and there was no inflammatory areola in any of the lesions. The lesions were practically all discrete, and there was no generalized plantar keratosis.

A very notable feature in all the cases that have been recorded is the simultaneous presence of gonorrhoeal arthritis, and mostly in men who have had a previous attack of gonorrhoea. The question naturally arises, What is the relation between the joint condition and the skin eruption, and what is the relation to the specific gonococcus? Are both manifestations of the presence of the gonococcus in the joints and tissues of the skin? Are they due to toxins emanating from the gonococcus, or are both trophic changes due to the gonococcus or its toxins acting through the central nervous system?—a view suggested and favoured by Jeanselme. He had noted in his cases that the reflexes in the lower limbs were greatly exaggerated.

Another notable feature is the rapid improvement of the skin lesions with the general progress of the patient. In none of the cases described has the gonococcus been found in the fluid aspirated from the joints.

LORD RHONDDA will contribute an introduction to the new edition of Sir William Crookes's book on *The Wheat Problem* which Messrs. Longmans will shortly publish.

THE special aural board of the Ministry of Pensions has now completed arrangements for the treatment of deafened soldiers and sailors at the Central London Throat and Ear Hospital, Gray's Inn Road, London, W.C., and at the Queen Mary Hospital, Stratford, Essex. The clinic at Stratford will open on the evening of October 10th, and the clinic at the Central London Hospital on the evening of October 12th. Applications for permission to attend the clinics are to be made to the local War Pensions Committees.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

LAPAROTOMY FOR GANGRENOUS GUT: DRAINAGE: RECOVERY.

On February 2nd, 1916, a lad of 18 consulted me for abdominal pain, the history being that he was awakened from sleep during the previous night by general abdominal pain, and then vomited. The bowels were opened.

On examination the temperature was normal, pulse 120. There was localized tenderness in the right iliac fossa. He was sent at once to another hospital as a case of acute appendix; but returned to me to watch for further developments. The whole trouble cleared up in a few days. In the second attack he was seen by another doctor, but the abdomen was not examined. The third attack was on August 28th, 1916. It was similar to the first, with a localized tenderness which cleared up in two or three days. He was attended by my partner, but I advised the patient to come into the London Temperance Hospital for appendicectomy.

The condition on September 25th was as follows: The patient was quite free from pain. The bowels were opened daily (takes salts occasionally). The abdomen moved well on respiration; no rigidity and no tenderness even on deep palpation in the right iliac fossa. On September 27th appendicectomy was performed by Mr. Arthur Evans. The appendix was red and very swollen, and suggestive of several acute attacks. On October 6th, 7th, and 8th, the patient vomited. Temperature and pulse were normal; bowels opened daily till October 7th, when they became obstinately costive. On October 11th, 13th, and 14th, there was again vomiting; bowels not opened; temperature normal, pulse 96; and on the 14th acute generalized abdominal pain set in. On October 16th the vomiting continued, and the temperature and pulse were both running up.

On October 17th at 2 a.m. a further operation was performed by Mr. Evans for acute obstruction. It was found that a Meckel's diverticulum had attached its tip to the site of the invagination of the appendix stump into the caecum, so that, at first sight, it looked exactly like the defunct vermiform appendix. This acted as a band, constricting several feet of small intestine greenish black in colour, which only very slightly improved on removing the constriction. The patient's condition was so poor that resection was out of the question, so Mr. Evans inserted a long drainage tube into the gangrenous gut, letting the free end fall into a pail by the bedside, and the patient was put back to bed with a prognosis as black as the gut.

However, the lad made a splendid recovery; a faecal fistula persisted, which was finally cut away after two smaller plastic methods had failed, and on May 5th, 1917, the patient left hospital with a soundly healed abdominal wall and bowels acting well daily.

I am indebted to Mr. Arthur Evans, F.R.C.S., for permission to publish these notes.

EVELYN A. CONSTABLE, M.B., B.S.,

'London, N. Surgical Registrar, London Temperance Hospital.

THE ETIOLOGY OF SO-CALLED TRENCH NEPHRITIS.

WITH reference to the views of a recent correspondent that hyperchlorination of drinking water may be one source of this disease, I have been of this opinion for many months, and am in a position to produce considerable evidence in its favour.

Having been on active service in France in positions from a base hospital to an infantry battalion in the fighting line, I have noticed that as a general rule "the nearer the unit to the front line, the heavier the incidence of the disease." In the front and support trenches the men are placed under extremely favourable conditions for the development of acute nephritis; but in former wars and in polar expeditions very similar conditions were present without causing the disease. It is clear, therefore, that a further etiological factor must exist.

On April 20th, 1917, on taking over medical charge of an infantry battalion, I found no Horrocks's test box, and the corporal in charge of the water-carts was adding a minimum of at least one measure of bleaching powder to each water-cart.

On June 6th the Horrocks's test box arrived, and I found on testing the water that the amount of organic matter, etc., present was very low. The amount of bleaching powder per water-cart was at once reduced to a maximum of one half-measure, and it has never exceeded that amount since.

We have thus two periods: (a) April 20th to June 6th, forty-seven days, never less than one measure of bleaching powder per cart, and often more; (b) June 6th to July 12th, thirty-six days, never more than half a measure of bleaching powder per cart, and often less.

During period (a) there were numerous complaints of hyperchlorination of the drinking water (verified personally). There were seven cases of acute nephritis. During period (b) there was only one complaint of hyperchlorination. There were no cases of nephritis. The other living conditions—that is, trenches, etc.—of the battalion during the two periods were identical.

The hyperchlorination may be absolute, too much bleaching powder per water-cart; or relative, parts only of the water in the cart are hyperchlorinated owing to insufficient admixture and shaking up of the added powder. In my opinion the drinking of hyperchlorinated water by a recruit recently arrived in France, and placed suddenly under conditions imposing great strain on the kidneys, frequently determines the onset of an insidious toxic nephritis closely resembling the renal type of eclampsia in the female.

Subjoined is a list of cases of acute nephritis, with the duration of their service in France:

Service in France of Patient.				
May 4th	...	Corporal L.	...	4 months.
May 8th	...	Private B.	...	4 "
May 17th	...	Private P.	...	4 "
May 19th	...	Private C.	...	4 "
May 20th	...	Private P.	...	4 "
May 20th	...	Private R.	...	5 "
May 30th	...	Private F.	...	5 "

The battalion to which the men belonged had been on service in France for seventeen months.

S. A. BULL, M.D.Lond.,

Temporary Captain R.A.M.C.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

No. — BRITISH GENERAL HOSPITAL, MESOPOTAMIA.

COMA DUE TO SUPPURATIVE MENINGITIS: DIFFICULTY OF DIAGNOSIS.

(By Captain C. E. H. MILNER, R.A.M.C.(T.), Registrar.)

I HAVE ventured to record notes of the following case, which has recently come under my care at the above hospital, as it is illustrative of the difficulties in differential diagnosis under war conditions in a tropical climate.

Pte. T. was admitted to hospital with a statement from the medical officer in charge of his dépôt that he had been in an abnormal mental state for some two or three days. He had been kept in bed under observation, and on the day of his admission to this hospital he had been continually getting out of bed "to paddle in puddles of water." When questioned by the orderly medical officer as to what was the matter with him, he replied, "A pack of cards." These appear to have been his last words, for when I saw him in the mental observation hut about a quarter of an hour later he was already unconscious.

He was a big man, whose age was said to be 39, but who looked 50. The pulse was full and bounding, but of no great tension. The heart was hypertrophied, and the aortic second sound was a little "blurred." The temperature was 101.4° F. The left knee-jerk was lost, but the right normal; both plantar reflexes were flexor; both the corneal and the abdominal reflexes were lost. Kernig's sign was absent; there was conjugate deviation of the eyes to the left. Examination of the optic discs was difficult, and that of the urine impossible, by reason of incontinence.

In peace time this would have been at first sight a case of granular kidney with cerebral haemorrhage. But there were no localizing signs of paralysis, and the plantar reflexes were normal. The possibility of malignant malaria of the cerebral type led me to have his blood examined, but with a negative result. Although it was in Mesopotamia, and in June, the previous four or five days had been unusually cool, owing to the early Shimal, so that a diagnosis of heat-stroke was by no means certain. To my mind the diagnosis lay between cerebral haemorrhage and heat apoplexy, and, as the treatment would tend to benefit either condition, I decided on venesection followed by infusion. By this time the pulse had begun to fail, and the rectal temperature was found to have risen to 105.6° F. The patient bled sluggishly, normal venous blood, and was not improved by saline infusion. He died at about 1.30 a.m.

An autopsy was performed, which confirmed none of the above possibilities. It is true that there were several small haemorrhages in the anterior horn of the lateral ventricle, which may or may not have been the ultimate cause of death. But the striking feature of the examination was the discovery of a sero-purulent basic meningitis and of a large abscess in the left frontal lobe. Pus from this gave a pure culture of meningococci. The cisterna magna and all the ventricles were distended with sero-purulent fluid, and the meninges in relation to them were hyperaemic and inflamed.

The situation of the abscess explained the semiambulatory form of the illness, the mental condition, and the absence of any localizing neurological signs. I hope I may be forgiven for having failed to make the correct diagnosis.

Rebuelus.

HEAT-STROKE IN MESOPOTAMIA.

CAPTAIN H. STOTT, I.M.S., has written an interesting account of his experience of hyperpyrexial heat-stroke in Mesopotamia during 1915,¹ and comes to the conclusion that in many cases it was evidence of a malarial infection. and in some others was connected with the enteric group of fevers. The heat in the Persian Gulf during June, 1915, was intense, and the relative humidity of the atmosphere very high. During June, July, and August of that year 58 cases of heat-stroke were treated on board his hospital ship. Two only of the patients were Indians, the remainder were Europeans. Captain Stott remarks on the well-known rarity of pure heat-stroke among Indians, and adds that one of the two patients had enteric fever (the temperature of the body reaching 108° F., and 112° F. *post mortem*), the other relapsing fever. Amongst Europeans heat-stroke is commoner in those without previous experience of hot weather in the tropics, those of full bodily habit and a tendency to the consumption of alcohol, and those in a generally low state of health and below par for some reason or another. As regards the 56 European patients with heat-stroke, Captain Stott found that they were not without the experience of some months of life in India and the Gulf, and that intemperance was a contributory cause in but one or two of the cases. Careful examination in 33 of the instances showed that 13 had an active concomitant malarial infection, and that in 5 more the presumptive evidence in favour of malaria was very strong. Usually the patient was struck down suddenly with a well-marked heat-stroke of 107° or 108° F., and malarial parasites were subsequently found in the blood; no doubt definite cerebral malaria was present in some cases. Seven others of the 33 patients gave a positive Widal reaction that was sufficiently strong to be taken as evidence of an enteric-group infection; typical typhoid ulceration in the jejunum and upper ileum was found in one case with a fatal ending. Two of the 7 also had an active malarial infection. In 8 only of the 33 cases of heat-stroke was there no clear evidence of any concomitant infective process; naturally cases of pure uncomplicated heat-stroke do occur. Captain Stott comes to the general conclusion that directly the diagnosis of hyper-

pyrexia becomes clear in any case the patient should be placed in the coolest possible place, stripped, and cooled by water or ice as soon as possible, without a moment's delay, until the rectal temperature falls to 102° F. No alcoholic stimulant should on any account be given, but an intramuscular injection of 10 grains of bilydrochloride of quinine should be administered. Evidence of the concomitant infection presumed to be present should be looked for, and the subsequent treatment of the case determined by the results of the examination.

PRACTICAL X-RAY WORK.

OMBRÉDANNE and LEDOUX-LEBARD have published an interesting book on localization and removal of foreign bodies,² based upon their experiences in France during the present war. As will be seen from the title, the authors do not limit themselves merely to the demonstration and localization of bullets and such like objects by radiography, but go wider afield and extend their work to a consideration of the elaboration of methods so as to give the surgeon the greatest assistance possible in the operations for the removal of the foreign bodies. In this respect the authors address themselves equally to surgeons and radiographers. The monograph is most comprehensive; whilst it does not profess to discuss each and every device and variation of manipulation which has been advocated, nevertheless practically everything of any real importance bearing on the subject is fully considered. One interesting point becomes very evident in the course of reading this volume—namely, that similar ideas of technique, and similar ideas of instrumentation, have occurred to British and French workers at the same times. Methods and instruments to which we have been accustomed to attach British names we find attributed to well-known French workers. In the general scheme a division is made into two main parts—the first being given up to the finding of, and the localization of, foreign bodies; the second to their extraction. In addition, there are four introductory chapters which deal with the indispensable knowledge of x-ray work and physics necessary to a complete understanding of what follows. There are many illustrations; diagrams, and not picture radiographs, predominate, and form an important part, inasmuch as they visually interpret the text. Whilst comprehensive and detailed, the descriptions are easily followed, and, indeed, made quite simple by these admirable diagrams. All radiographers and surgeons doing war work will find this textbook full of practical information and valuable suggestions.

The second edition of ARTHUR and MUIR's *Manual of Practical X-Ray Work*³ has been brought thoroughly up to date, and is one of the best of the smaller books on this subject. The first half consists of a description of various x-ray apparatus and a short chapter on the photography of the subject, whilst the second half deals with x-ray diagnosis and therapeutics. This is a common fault in the arrangement of books on x rays. It means that whilst half the book is an elaboration of the instrument makers' catalogues and the illustrations they contain, the second and more valuable part is often unduly compressed. The chapter on localization of foreign bodies is good. The most important and valuable methods are described very simply, and no attempt is made to refer to the very numerous, and mostly worthless, methods which have been advocated by various inventors. It seems a pity that the chapter on orthodiagraphy should have been retained now that this method of examination has for practical purposes passed out of use. The chapter on photography, which deals with the various photographic processes of value in x-ray work, has been rewritten and extended, and on the whole is reliable and practical. The second portion of the book, dealing with diagnosis and x-ray treatment, passes in somewhat rapid

¹ *Studies in Malaria*. By Hugh Stott, M.B., B.S. Lond., Captain I.M.S. Calcutta: Thacker, Spink and Co. 1916. (Demy 8vo, pp. xvi + 190; with maps, charts, and illustrations. 10s. 6d.)

² *Localisation et extraction des projectiles*. By L. Ombredanne, Chirurgien des Hôpitaux de Paris, and R. Ledoux-Lebard, Chef de Laboratoire de Radiologie des Hôpitaux de Paris. Collection Horizon: Précis de Médecine et de Chirurgie de Guerre. Paris: Masson et Cie. 1917. (Cr. 8vo, pp. 353; 225 figures, 8 plates. 4 fr.)

³ *Manual of Practical X-Ray Work*. By David Arthur, M.D., D.P.H., and John Muir, B.Sc., M.B., Ch.B. Second and revised edition. London: William Heinemann. 1917. (Demy 8vo, pp. xiv + 351; 195 figures. 12s. 6d. net.)

review the various conditions in which radiography and x-ray therapy are indicated, and gives a fair idea of the present-day scope of this kind of work. There are many illustrations throughout the book, pictures of various apparatus, radiographs of normal and of abnormal conditions, and a series of diagrams demonstrating many of the points discussed. More care might, however, have been employed in the choice of illustrations, for, whilst many are good, some are not good, especially those used to illustrate the condition of the thorax, in which radiographs are of value in diagnosis. They do not do justice to what is one of the most striking and dramatic uses of x rays. The best part of the section allotted to therapeutics is that dealing with the treatment of ringworm; the method is described in full detail and well illustrated. As a whole this volume is an admirable introduction to an important subject, and beginners in x-ray work should find it of use.

CHEMISTRY FOR MEDICAL STUDENTS.

An excellent *Textbook of Organic Chemistry*⁴ for students of medicine and biology has been written by Professor McCOLLUM of the University of Wisconsin. It is arranged on what may be described as the usual lines, beginning with an account of the simpler organic compounds such as the hydrocarbons, alcohols, ethers, esters, and the like, and ending with brief chapters on such highly complex compounds as the terpenes, alkaloids, organic arsenical compounds, and proteins. Professor McCollum omits reference to laboratory and technical methods of preparation, and devotes most of his pages to descriptions of the biologically important compounds and the proof of their structural formulas wherever possible. In this way he presents the student with the how and the why of the reactions of organic chemistry, and sets him on the way to understanding some, at any rate, of the complicated but intensely interesting reactions of physiological and biochemical importance upon which explanations of life as a series of chemical processes must rest. The book is clearly written, and its author is to be congratulated upon the selection of the material it contains. It would, perhaps, gain by the insertion of a little more information about glycuronic acid, a substance of such common occurrence in the urine, and explanations of the derivation of such terms as "mercaptan," "alkyl," "cis," and "trans," would probably be welcomed by most students who use the book. A few misprints may be noted: "Cannizzaro," on p. 61, should be "Cannizzaro"; the use of the symbol "ba" to express a single valence of the metal Ba (p. 152) is not free from objection in a book for beginners; on p. 205 "chlor ethylacetate" should be "ethyl chloracetate"; on p. 375 "alkaptonuria" should be "alcaptonuria," in accordance with Boettcher's original spelling of the word, and "alizerin," on p. 386, should be "alizarin"; there is nowadays no justification for calling the metal aluminium by the name "aluminum" (p. 358). All these, however, are but trifling faults in what is a good book for students of elementary organic chemistry which may be cordially recommended to the attention of medical and physiological students.

The second edition of Dr. CUMMING'S *Practical Chemistry for Medical Students*⁵ is an excellent and practical handbook for laboratory use. It begins with exercises illustrating the properties and preparation of simple chemical substances, and has a good chapter on volumetric analysis. The last hundred pages deal with qualitative analysis; here some simple experiments and tests more properly belonging to elementary physiological chemistry have been introduced—very wisely, in our opinion, as the untutored student is apt to store his knowledge in compartments that do not communicate with one another, and to miss the interdependence of all the forms of chemistry he is set to learn—physical, inorganic, organic, and physiological. The use of Dr. Cumming's book will do something to bring home to him the essential continuity of these branches of

chemical science. The volume may be warmly recommended to those for whom it has been written.

Dr. STEEL'S *Laboratory Manual of Organic Chemistry for Medical Students*⁶ is a well-designed volume laying out a somewhat ambitious course for the embryo practitioner of medicine. To have worked through the many tests and preparations described in the book, and to have made adequate notes on the blank pages with which it is interleaved, would afford a first-rate training for the medical student. In this country one fears that time would be lacking for so thorough a course of training in organic chemistry, important as that subject is for the study of medicine. With this qualification, however, the volume is thoroughly to be recommended.

NOTES ON BOOKS.

THE Isles of Aran, thirty miles from Galway, and much exposed to the storms of the Atlantic, are little known. Ten years ago the Irish dramatist, John Millington Synge, wrote the story of his summer's experiences, and now an equally fascinating description of life all the year round, more particularly of the winter storms and her perilous voyages as a district nurse, has been written by Miss HEDDERMAN.⁷ In the chapter on some first cases a most graphic account of the dangers she experienced in going from one island to another to attend urgent calls makes the reader see the bravery of the natives and their skill in paddling the curragh—a frail canvas craft—through the angry seas. The authoress clearly loves these desolate islands, and gives an interesting account of their superstitions and customs, which are especially barbarous from a medical aspect, perhaps the least harmful being that the first person entering the room after the birth of an infant must spit upon the newborn, then on the mother, and finally on the nurse, doctor, or attendant, as a lifelong preservative for the child and its parents. The charm of the style and the interest of the matter are so irresistible that it is to be hoped further instalments will soon appear.

The third edition of *One Hundred and One Practical Non-Flesh Recipes*,⁸ by MARGARET BLATCH, is an excellent book for vegetarians and those who wish to substitute strange but appetizing and nutritious foods for meat. In this edition twenty-six additional recipes for dishes and cakes made of maize, oats, barley, and rice have been inserted. We recommend the book.

⁴ *A Laboratory Manual of Organic Chemistry for Medical Students*. By Matthew Steel, Ph.D., Professor of Organic and Biological Chemistry, the Long Island College Hospital, Brooklyn, New York. First edition. First thousand. London: Chapman and Hall, Limited. New York: John Wiley and Sons, Inc. 1916. (Med. 8vo, pp. viii + 193. 6s. net.)

⁸ *One Hundred and One Practical Non-Flesh Recipes*. By Margaret Blatch, M.C.A. Third edition. London: Longmans, Green, and Co. 1917. (Fcap. 8vo, pp. 92. 1s. 6d. net.)

MEDICAL AND SURGICAL APPLIANCES.

A Modified Anchor Tourniquet.

CAPTAIN C. MAX PAGE, R.A.M.C.(S.R.), writes: In the ordinary pattern of Samway's tourniquet, though the anchor catch gives a satisfactory hold, it is not easy to fix the instrument at the required tension, nor can it be rapidly detached.

These shortcomings are due to the lack of any part of the apparatus upon which a firm purchase can be obtained. To provide this I have had a handle added in rigid continuity with the anchor. The form is sufficiently shown by the illustration.

It will be found that a tourniquet fitted with this modified anchor can be readily applied at any tension, and can be rapidly detached, even when out of sight. The pattern shown has been made for me by Messrs. Allen and Hanburys, Wigmore Street, W.

⁴ *A Textbook of Organic Chemistry for Students of Medicine and Biology*. By E. V. McCollum, Ph.D., Professor of Agricultural Chemistry, University of Wisconsin. New York: The Macmillan Company. 1916. (Post 8vo, pp. 438. 10s. net.)

⁵ *Practical Chemistry for Medical Students*. By A. C. Cumming, D.Sc. With Preface by Professor James Walker. 2nd edition. Edinburgh: James Thin. 1917. (Demy 8vo, pp. 173; 15 figures.)

SATURDAY, OCTOBER 6TH, 1917.

THE AIR WAR.

Those who prophesied a year or more ago that the development of the war in the air would be so rapid as to become an important factor in the whole field of operations have been more than justified. The official reports of all the belligerents contain almost daily accounts of the activities of the airmen on the several fronts, the most important work being undoubtedly the results of observation of enemy preparations behind the line, enabling the guns to register all enemy defences and assemblies of troops; this registration is immensely helped by photographs taken by the observers in airplanes, which show with the utmost clearness the plan of trench systems, the disposition of blockhouses, and, what is extraordinarily interesting, the results next day of the fire of the long-range artillery thus directed. But the Germans, in pursuance of their policy of frightfulness, have made the bombardment of open towns from the air a part of their general war methods, inasmuch that London for ten days, about the full moon, has been subjected to almost daily bombardments. The number of casualties has been relatively small, and it has been calculated that the Londoner's chance of being hit is 69,999 to 1; the material damage also has been small, both results, it is believed, being due to the effectiveness of the defensive air barrage. But this barrage is not only a source of danger from the falling splinters of our own exploded shells, but the noise is nerve-racking. It has undoubtedly had an injurious effect upon many people in delicate health or of nervous disposition, but the general behaviour of the inhabitants of the great province of houses which extends into five counties surrounding the city of London itself has been admirable. The injunction to take cover after the warning is given has been generally obeyed, owing, no doubt, in no small measure to the evidence afforded by coroners' inquiries that the majority of persons injured have failed to follow out instructions.

The only exception to this good behaviour has been afforded by certain elements of the alien population of the east end, who have crowded into the tubes and thronged the platforms of the principal railway stations and the trains going even as far as thirty or forty miles from London. Arrived at their destination, they have naturally experienced great difficulty in finding accommodation, and though efforts have been made by municipal authorities to house them in public buildings, many of them have been sleeping out. The people of the localities thus invaded, though they do their best to fulfil the dictates of humanity, cannot regard the invasion with anything but distaste, mingled with some contempt for the attitude of mind disclosed; in fact, it will not be surprising if a public demand arises either for the deportation of these persons or for their segregation in camps, where the elementary principles of hygiene can be enforced.

The exodus of these foreigners has been used as an argument for a policy of reprisals; it is being contended that if air raids and the measures taken for their repulse can produce such a state of

nerves in these aliens, it is probable that raids over German towns would have a similar effect on their inhabitants. The French have, indeed, recently carried out this policy on a small scale. The Germans admittedly raid London and other English towns in order "to paralyse the enemies' war spirit," and it is argued by some, as, for instance, by Sir Henry Morris in a letter published in the *Times* of October 3rd, that by raiding every accessible place in Germany, not sporadically and intermittently, or by way of reprisals, but systematically and continuously as a deliberate and justifiable policy, the Germans can be made to realize that their Kaiser and his military despotism are unable to give them security, and that to obtain peace they must alter their aims, methods, and politics. A semi-official pronouncement published the day before asserted that there is in this country no reluctance to raid the enemy's towns, but that while the great battle on the Ypres front continues it is of the first importance that all necessary and available military resources should be concentrated there. This, no doubt, is an admission that we have not got enough aeroplanes, and we have the statement of Dr. Addison, then Minister of Munitions, that only in January last were the whole of the internal resources of the country mobilized to deal with the manufacture of aeroplanes. This is another example of the ineptitude of the policy of "wait and see" when practised during a great war. Dr. Addison went on to say that already the output "has been increased at a gigantic rate and will increase very much more." It is also to be remembered that raids from the Ypres front are made "systematically and continuously" on the aerodromes in Belgium from which the marauders start, and we are inclined to answer in the affirmative Mr. Spencer Wilkinson's question when, in another letter published in the *Times* of October 3rd, he asks whether the right way to stop air raids on London is not to destroy the German aeroplanes in Belgium. His argument that it is better for our defence to send more British aeroplanes to France for the destruction of the enemy's aeroplanes than to make air raids on German cities, which can have no direct military purpose, is in accordance with the military traditions of the British nation—traditions which have been tested and not found wanting ever since the great sailors of the eighteenth century concentrated their strategy, in spite of much criticism at home, on seeking out and defeating the enemy fleets. It is, in fact, the application of the old medical principle that prevention is better than cure. The surest way of prevention in this case is to destroy the means of aggression.

A very ugly development of barbarous German methods is seen in the deliberate bombing of advanced hospitals on the Western front, both of the British and the French armies. At first the staffs at the British front believed that the damage done to casualty clearing stations was accidental, for these medical units must often be about as far back as heavy artillery posts; we believe, however, that those on the spot are now convinced that this charitable explanation is not true, and that one fact which has helped to produce this conviction is that air raids have recently been made over hospital bases on the French coast, during one of which an American surgeon was killed. The French staff was convinced of the deliberate nature of the bombing a month or six weeks ago; the story told of an aeroplane which flew low, backwards and forwards, over two adjacent advanced hospitals behind the Verdun front left, indeed, little room for doubt. We believe

that a considerable proportion of the casualties recently reported in the R.A.M.C., both among officers and men, have occurred in casualty clearing stations, and the country has been distressed to see in the casualty list issued on October 2nd the names of four nurses—three of the Army Nursing Service Reserve and one of the Territorial Nursing Service—among the list of wounded. As Mr. Frederick Harrison has well said, we cannot copy the crimes of the Germans and can take no hand in such abominations; here, again, it would seem that the real remedy is to give the German aerodromes no rest and to continue the policy of bombing them and setting them on fire that has been successfully practised during the last month or more.

It has frequently been asserted that the co-operation between the two air services the country possesses has not always been sufficiently close and cordial, and that in particular there has been competition between them to obtain early delivery of the newest types of machines. If the statement, apparently authoritative, that the War Cabinet has decided to create an Air Ministry prove correct, a unification in supply and distribution of machines and their strategical use may be achieved which will put a term to our present civilian discontents.

THE HEALTH OF THE SCHOOL CHILD.

THE annual report¹ for 1916 of the chief medical officer of the Board of Education, though slightly longer than its predecessor, is necessarily a much smaller volume than we were accustomed to before the war. In his prefatory letter to the President of the Board, Sir George Newman shows his consciousness of what Herbert Spencer called "physical morality" as a preponderating factor in the rearing and training of children. He defines school hygiene as the branch of public medicine which is concerned with all that affects the healthy physical development of the child of school age. Its foundations are laid, first, in a system of education favourable to sound physical growth; next in a suitable school environment; and, lastly, in the medical supervision of the individual child. School hygiene is thus an integral part—one might even say the mainspring—of the public educational machine. It likewise forms a part of the public system of State medicine. Presented in this way, the idea of school hygiene is seen as no narrow notion called "medical inspection," but as an ideal towards the realization of which much has been done in the past decade, though very much remains to be achieved. The war more than anything else has brought home to the public the conception of the child as a primary national asset. Writing of the "volume of national inefficiency, of unfitness and suffering, of unnecessary expenditure, and of industrial unrest and unemployability to which this country consents because of its relative failure to rear and to educate a healthy, virile, and well-equipped race of children," Sir George Newman lays down the principle that no investment and no national economy can compare in results with care for the rising generation. Even more important in our view is his insistence that the goal of primary education is not an industrial "hand" but a healthy human personality—a good citizen. Thus we are carried with him to his logical conclusion that no reconstruction of the State can wisely ignore the claim of the child.

Although progress has been made, and has been maintained even in time of war, there is no room for

complacency. The records of the findings of the school medical service in 1916 show all too much ill health, disability, and defect of mind and body. Uncleanliness, malnutrition, and mental backwardness debar tens of thousands of children from reaping proper advantage from the educational system provided by the country. Disease takes even heavier toll of the six million children in attendance at school. We learn that probably half the whole number need dental treatment, and not less than half a million need it urgently, while a further half-million are so defective in eyesight as to be unable to take reasonable advantage of their lessons. Another quarter of a million are seriously handicapped by diseases of the ear, throat, and lymphatic glands. A year ago it was estimated in round figures that a million children of school age were so defective or diseased in body or mind as not to be able to profit reasonably by education, and there are no grounds for supposing that things are appreciably better at the present day.

The investigations of the school medical service have thus revealed the gigantic size of the evil. What is to be done? In the opinion of Sir George Newman the evil is only remediable by systematic and continuous attention. The necessary machinery is in existence; "in some areas," he says, "it is yielding adequate returns; in other areas it is insufficiently applied, or misapplied, to the problems presented; and in other areas, again, particularly in regard to medical treatment, it is in abeyance, or wholly ineffectual, due in part to a failure to foresee the vital importance to the nation of the health of the children and in part, perhaps, to a sense of false economy or even parsimony."

The problem is by no means simple, nor can it be solved by merely applying the whip and the spur to inert and obstructive local education authorities, for persons and authorities outside their control share their responsibilities and their powers. At each stage of the child's passage from infancy to adolescence there is overlapping, confusion, and competition among the authorities charged with his care; and, indeed, it is so throughout the seven ages of man. It is recognition of this which has given such strength to the movement towards a Ministry of Health. As an official Sir George Newman naturally confines his suggestions for reform to the matter immediately in hand, but his words are capable of a far wider application. "What is needed," he says, "under existing circumstances and under existing law, is therefore an effective unification of all the powers having for their purpose the healthy upbringing of youth," and "an understanding of the whole problem as one and the same problem and an administration of the law affecting it as a unified and co-ordinated administration in every locality."

The introduction to the report concludes with a statement of the steps necessary from the medical point of view in order to secure the full value of the school medical service to every child of school age in each area. They are defined in a series of seven propositions, together constituting a minimum standard of the physical claim of the individual child. These requirements are as follows: (1) That every child shall periodically come under direct medical and dental supervision, and, if found defective, shall be "followed up." (2) That every child found malnourished shall, somehow or other, be nourished, and every child found verminous shall, somehow or other, be cleansed. (3) That for every sick, diseased, or defective child skilled medical treatment shall be made available, either by the local education authority or otherwise. (4) That every

¹ Annual Report for 1916 of the Chief Medical Officer of the Board of Education. [Cd. 8746.] London: H.M. Stationery Office. (Is. net.)

child shall be educated in a well-ventilated school-room or classroom, or in some form of open-air school-room or classroom. (5) That every child shall have, daily, organized physical exercise of appropriate character. (6) That no child of school age shall be employed for profit except under approved conditions. (7) That the school environment and the means of education shall be such as can in no case exert unfavourable or injurious influences upon the health, growth, and development of the child.

Simple, and we might add self-evident, as each proposition is, Sir George Newman admits that together they comprise a somewhat formidable policy of child welfare. They cannot all be realized immediately, but they embody principles which every local education authority should be compelled to recognize and to carry into practice to the best of its powers. By such means "the normal child, who after all is more important to the nation and to the future than the deficient child, may grow strong, healthy, and capable." With the information closely packed within the body of the report we hope to deal in a later issue.

GERMAN PRISON BRUTALITIES.

WHEN we in this country first began to realize that prisoners, both military and civil, in German hands were being ill treated, and kept under conditions which must inevitably lead to the spread of typhus and other epidemic disease, we had, in order to check the individual stories that came through, to depend largely on the official reports of the American Ambassador at Berlin and his staff. Taking these reports and the scientific descriptions of the epidemics given by British medical officers who escaped with their lives from the camps, especially that by Major Davy and Captain A. J. Brown on two thousand cases in a single prison camp (at Gardelegen) published in this JOURNAL on November 20th, 1915, it was pointed out that the German apologists had the choice of two alternatives, and two only: either they were acting with deliberate malice in the expectation, which was fulfilled, that large numbers of their captives would suffer horribly and that many would die, or they were displaying gross ignorance and incompetence. After a time Mr. Gerard's reports stopped because, it now appears, German officials affected to regard true statements as insults. Undoubtedly if they had not been true they would have been insulting. Mr. Gerard, in one of the chapters of his book *My Four Years in Germany*, which has been appearing in the *Daily Telegraph*, says: "I did not find the Germans at all efficient in the handling of prisoners of war. The authority was so divided that it was hard to find who was responsible for any given bad conditions. For instance, for a long period of time I contended with the German authorities for better living conditions at the civilian camp of Rühlleben. I was promised time and again by Colonel Friedrich, by the camp commander, and by the Foreign Office that these conditions would be remedied. In that camp men of education, men in delicate health, were compelled to sleep and live six in a box stall, or so closely that the beds touched each other; in hay lots, the outside walls of which were only four feet high. Finally, almost in despair, I wrote identical personal letters, after having exhausted all ordinary diplomatic steps, to General von Gessel, Commander of the Mark of Brandenburg, to the commander of the corps district in which the Rühlleben camp was situated, and to the Minister of War. The only result was that each of the officers addressed claimed that he had been personally insulted by me because I had presumed to call his attention to the inhuman conditions under which the prisoners were compelled to live in the Rühlleben camp." Mr. Gerard says, however, that undoubtedly the worst

prison camp was that of Wittenberg. At first he and his staff were unable to visit this camp owing to the outbreak of typhus fever, but one of his staff was able to converse with some of the prisoners from outside the barrier of barbed wire. Mr. Gerard states that the Russian soldiers arriving at Wittenberg were not properly disinfected and that the outbreak of typhus fever was the consequence. The British medical officers in the camp protested to the camp commander against the herding together of the French and British prisoners with the Russians, who were already suffering from typhus fever, but the camp commander said, "You will have to know your allies," and kept all his prisoners together; thus, as Mr. Gerard says, he "as surely condemned to death a number of French and British prisoners of war as though he had stood them against the wall and ordered them shot by a firing squad." Mr. Gerard confirms the statement that the camp during the epidemic was virtually deserted by the Germans, and that the German doctor did not make as many visits to the camp as the situation required. He also confirms the story that dogs were kept, not only outside the camp, but inside, where they attacked the prisoners. It is also undoubtedly true, he says, that the prisoners were knocked about and beaten in a terrible manner by their guards. In response to very vigorous protests by Mr. Gerard, the dogs were withdrawn, but the whole story reveals a mixture of incompetence and callousness which, until we were made acquainted with German mentality, would have been considered incredible in officers employed by a nation which considers itself civilized.

THE STUDENT'S OUTLOOK.

SINCE the war the inaugural address at the opening of the winter session of the medical schools has largely fallen into abeyance, but a few hospitals still maintain the custom. At Charing Cross Hospital, on October 1st, under the presidency of Sir Herbert Waterhouse, the prizes were distributed, and an address given by Dr. Christopher Addison, Minister of Reconstruction, a former member of the teaching staff. Dr. Addison first spoke of the shortage of medical students. He quoted from the figures which were given in a leading article in last week's JOURNAL, and reached much the same conclusion—namely, that for some years to come the medical profession will not be recruited in a sufficient measure to overcome the ordinary civil wastage, to say nothing of the losses directly due to the war. Hence the necessity for more recruits, and the obligation on those continuing their studies to make the best of their opportunities. Taking Sir George Newman's annual report, to which we refer this week, as a text, Dr. Addison spoke of the great work which lies before the profession of medicine in assisting to cope with the problem of national disability, and in taking its due share in a sustained and comprehensive programme of health effort. His own position in the Government added force to his remark that the tasks lying to the hand of the statesmen of medicine are great enough for the most ambitious, and that in their fulfilment the profession can, if it will, play a great part. Taking a wide view of the future, he came to the conclusion that there have not been for some generations brighter or better opportunities for those now entering the profession of medicine. At the London (Royal Free Hospital) School of Medicine for Women the opening ceremony was presided over by Dr. Louisa Aldrich-Blake, the dean, who stated that the addition of 110 new students brought the total numbers of the school up to 450. Dr. Louisa Garrett Anderson, in the course of her inaugural address, spoke of ambition in its best sense, and of the ideals which women medical students should keep before them throughout their career. In her belief the medical profession was the finest vocation for women, but beyond that it furnished the best training for public life. (Great as was the

importance to women medical students of personal success, this could not be so satisfying as the idea of enriching the profession they had joined and making it greater and more attractive.

MEDICAL NOVELISTS.

It might have been expected that doctors would have excelled as writers of fiction, especially of the psychological kind. Their training makes them skilful in observation and they see human nature as it is when divested of shams and affectations. Yet few of them have attempted this kind of literature and very few have succeeded in it. If a man is actively engaged in practice he has little time for the cultivation of any literary gift he may possess, and the very closeness of his contact with the grim realities of life interferes with the play of imagination and gives a hardness to his conceptions which makes it difficult to mould them into the forms of art. The doctors who have been successful as writers of fiction are nearly all men who have left their original profession for literature. But it is interesting to note how their medical knowledge reveals itself in their work. It is shown not only in the avoidance of the grotesque mistakes which even the most careful non-medical writer can hardly hope to escape, but in the clear notion they have of the intimate relation between the body and the mind and of the manner in which heredity and physical constitution shape the character. Zola made large use of the phenomena of disease and theories of heredity in his fiction; he collected facts with the most laborious industry, but want of first-hand knowledge often betrayed him into misconception and error. On the other hand, although Rabelais was a doctor only by second intention, so to speak, he had a regular training in the medical science of his day and actually practised as a physician. The result is that *Pantagruel* and *Gargantua* are pervaded and, in the scholastic sense, informed by his medical knowledge. Numerous illustrations from anatomy and physiology are to be found in his writings, and he planned out a scheme of education which proves how sound a conception he had of hygiene and of the need for physical as well as mental training in the education of the young. At the annual dinner of the Norwich Medico-Chirurgical Society in 1904 Sir Arthur Conan Doyle expressed the conviction that whatever line of life a man went into, as long as he was to use his brain, the medical training was absolutely the best he could undergo, for by no other means could he get to the fundamental and absolute facts of life. In connexion with this pronouncement we may recall the fact that Turgueniev frequently regretted that he had not studied medicine; he took every opportunity of repairing this omission by attending lectures on medical subjects. The creator of Sherlock Holmes has made considerable use of his professional experience in his novels, and in particular he has described the "qualified quack" with an insight that only what Iago calls his own gained knowledge could have given. Weir Mitchell has drawn a companion picture, but with less subtlety, in his *Autobiography of a Quack*. In *Roderick Random*, *Peregrine Pickle*, and elsewhere Smollett has given us the "form and pressure" of the medical profession in the eighteenth century. Goldsmith, who studied medicine in an erratic way at Edinburgh, Leyden, and Padua, used whatever knowledge he picked up chiefly in the exposure of quackery. Oliver Wendell Holmes, in his story *Elsie Venner*, which was unkindly called a "medicated novel," has described with great power a very abnormal and far-fetched instance of inherited instinct. And in the Autocrat's monologues on things in general medical illustrations occur almost on every page. Sir Henry Thompson tried his versatile hand at novel writing, but with indifferent success. Perhaps the best account of the advantages of medical study to a writer of fiction is given by Anton Pavlovitch Tchekhov, who died in 1904 at the age of 44. He was in the first rank of

contemporary Russian writers. He had studied medicine at Moscow, where he graduated in 1884, and his scientific training made his outlook on life more penetrating and far-seeing than it would otherwise have been. He had in an eminent degree the power of picking out the essential features of a phenomenon or an event, and entering into the minds of others and, as Goethe puts it, imitating their manner of conceiving. This he considered to be in a large measure the outcome of his medical training. He says in his autobiography: "That study (medicine) greatly enlarged the field of my observations, enriched me with knowledge of which the true value to me, as a writer, can be appreciated only by those who are themselves doctors. Those studies also exercised on me a directing influence, and it is probably thanks to medicine that I have succeeded in avoiding a number of errors. Knowledge of natural science and of scientific methods has obliged me to keep myself constantly on my guard. I took care, wherever possible, to conform to scientific truth, and when that was impossible I preferred not to write."

DIARRHOEA DUE TO EMETINE.

EMETINE, like some other valuable drugs—for example, arsenic—may, when given in considerable quantities, produce the symptoms which, when taken in more moderate doses, it tends to cure. Nearly two years ago Dale¹ threw out a warning as to the occurrence of chronic emetine poisoning based on experimental work, and now, from their clinical experience in China, Kilgore and Liu² show the importance of recognizing that emetine may cause diarrhoea, and record some cases in point. The difficulty is that the diarrhoeic stools due to emetine are almost indistinguishable to the eye from those of the amoebic dysentery for which the drug was given. Thus, a patient receives daily injections of emetine, with the result that the dysentery improves and amoebae disappear from the faeces which become more or less normal; then (emetine) diarrhoea occurs, with reappearance of mucus and blood, and if, under the assumption of a dysenteric relapse, the emetine is pushed, the condition becomes aggravated and death may follow, as in one case quoted by the authors. Fortunately, if the real cause of the secondary diarrhoea is realized and no more emetine given, recovery follows. Experiments by the authors and others show that in animals emetine may produce haemorrhagic gastro-enteritis with haemorrhages in the lymphatic glands, spleen, kidneys, and in the thymus of young dogs; these experimental animals die even if the emetine is discontinued directly symptoms appear. Kilgore, who previously wrote on peripheral neuritis following the emetine treatment of amoebic dysentery, will presently publish his observations on experimental peripheral neuritis induced by emetine.

THE MEDICAL INQUIRY COMMITTEE IN FRANCE.

THE committee appointed by the Secretary of State for War to inquire into various matters connected with the personnel and administration of the Army Medical Services in France and in the United Kingdom, which went to France on September 1st, has now returned to this country after visiting the various armies and bases, and examining a number of witnesses. It will, we presume, next proceed with its inquiry in this country, but we are inclined to think that it would be well advised to make an interim report at an early date with regard to army medical organization in France. We have no doubt that that report will show that the wounded and sick are being quickly, efficiently, and considerately treated, but it is to be anticipated that the committee will be able to make some recommendations as to economy of personnel, and these must, it is to be assumed, necessarily

¹ H. H. Dale, BRITISH MEDICAL JOURNAL, 1915, ii, 895.

² A. R. Kilgore and J. H. Liu, Arch. Int. Med., Chicago, 1917, xx, 178-185.

involve also some administrative suggestions. It will be remembered that the chairman of the committee is Major-General Sir Francis Howard, K.C.B., recently Inspector of Infantry, and that the other members of the committee are all medical men—namely, Sir Rickman J. Godlee, Bt., Sir Frederick Taylor, Bt., Sir W. Watson Cheyne, Bt., Lieut.-Colonel H. J. Stiles of Edinburgh, Dr. Charles Buttar, and Dr. Norman Walker; the secretary is Dr. J. B. Christopherson.

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.

THE general meeting of the profession to make better known the aims of the War Emergency Fund of the Royal Benevolent Fund and to nominate a general committee, which is to be held next Wednesday at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, will be presided over by Lt.-Col. Sir Alfred Pearce Gould, K.C.V.O., who will take the chair at 5 p.m. The means that can be taken to make the fund widely known, and to ensure its success, will be discussed, and it is hoped that the meeting will be largely attended. The fund was instituted last year to afford assistance to members of the profession who, in consequence of having to join the Army Medical Service, find themselves in temporary difficulties. Many medical men when called up had to leave on very short notice, without time to make adequate provision for the continuance and maintenance of their practices during their absence. Consequently they had to face a serious fall in income, even when supplemented by army pay, while many expenses, such as rent, insurances, taxes, family maintenance, and education could not be reduced. Although it may be hoped that in a year or two after their return those affected will recover their position, still in the interval help is and will be required. To be effective the grants made must be on a liberal scale, and the fund a large one. The amount obtained in 1916 was about £4,000, but at least £25,000 will be needed if even a small proportion of those requiring assistance is to be helped. The appeal is primarily to the medical profession, but is not restricted to it, and it is hoped that the public will be ready to bear its share, and to show by liberal contributions its appreciation of the special services so freely rendered by the medical profession to the country. The War Emergency Fund is a special department of the Royal Medical Benevolent Fund, and contributions should be made payable to the honorary secretary, War Emergency Fund, 11, Chandos Street, Cavendish Square, W.1.

WORMS AND THEIR SYMPTOMS.

ALTHOUGH it is impossible to name any particular group of symptoms which points clearly to the presence of intestinal worms, this is assuredly not because symptoms are wanting, but, on the contrary, because they are so numerous and at the same time so inconstant that no diagnostic value attaches to them. In children these parasites may determine convulsions and symptoms closely simulating the meningitic state. Most practitioners, too, have met with cases in which attacks of high fever, more or less resembling typhoid, turn out to be due to helminthiasis, in that all the manifestations disappear on the expulsion of the worm or worms. The ancients used to call this state "verminous fever." But it would be difficult to mention a symptom which has not at one time or another been noted in this connexion. Among those more frequently met with are: Cardiac arrhythmia, inequality of pupils, pruritus, attacks of giddiness or faintness, periods of pallor, photophobia, and spasm of the glottis. Nutrition may be gravely affected, so that in spite of a voracious appetite the subject grows steadily thinner and haematopoiesis is interfered with, leading to anaemia and more or less marked changes in the

leucocytic formula. Special local symptoms are associated with infestation by the *Ascaris lumbricoides* in consequence of its vagabond habits leading it into the larynx, nasal fossae, and the vermiform appendix. It has been credited with the causation of abscess of the liver, of intestinal obstruction, and has even been accused of setting up peritonitis. Recent publications make it clear that intestinal worms may determine symptoms closely resembling appendicitis. This recalls Metchnikoff's suggestion that, whenever there is a history of helminthiasis, or any reason to suspect its existence, it is well to try anthelmintic remedies before resorting to operation. Systematic examination of the faeces has shown the extraordinary prevalence of intestinal parasites among hospital patients, and therefore presumably among the general population. This method of diagnosis therefore deserves trial in obscure cases in which this etiological factor cannot be formally excluded.

TRAUMATIC LESIONS OF THE CERVICAL SYMPATHETIC.

THE multiplicity and various characters of wounds observed during the war have necessarily expanded our knowledge in many directions, and among such observations it is natural to extend a special welcome to those from the Belgian Army Medical Department. In an article entitled "Contribution à l'étude du syndrome Claude Bernard—Horner," a Belgian regimental surgeon, H. Burger,¹ discusses the manifestations of traumatic lesions of the cervical sympathetic. In 1858 Claude Bernard showed experimentally that paralysis of the cervical sympathetic caused (1) pseudo-ptosis due to paralysis of the involuntary muscle in the upper eyelid; retraction of the eyeball (enophthalmos) from paralysis of the smooth muscle fibres in the palpebral portion of Tenon's capsule, which normally antagonize the backward pull of the recti muscles; myosis with preservation of the pupil reactions; (2) dilatation of the blood vessels of the face and neck; excessive sweating; and eventually loss of tension in the eyeball and facial hemiatrophy. Clinically, traumatic lesions of the cervical sympathetic, long ago investigated by the late Sir J. Hutchinson, do not show such a constant syndrome; and though the motor phenomena are commonly present the other signs may be absent, as is brought out in Roche's recent analysis of eleven cases observed during the war. After touching on the various explanations of this dissociation and the light recently thrown on the subject by the effects of cocaine and adrenin on the iris, Burger argues that the frequent dissociation of the constituent signs of the syndrome depends on partial or slight damage of the cervical sympathetic, or possibly on a special susceptibility of some of its parts. In addition to the other signs he draws attention to transient diplopia, etiologically related to the enophthalmos.

THE Harveian Oration before the Royal College of Physicians of London will be delivered on Thursday, October 18th, at 4 p.m., by Dr. Robert Saundby of Birmingham.

THE Army Medical Exhibition in the Museum of the Royal College of Surgeons of England, Lincoln's Inn Fields, W.C., will be opened on Thursday, October 11th, at 3 p.m., by Sir Alfred Keogh, G.C.B., Director-General of the Army Medical Service, when the honorary fellowship of the College will be bestowed on him. The specimens which are to be on exhibition have been collected by officers of the R.A.M.C., and are being prepared and shown by members of the museum staff of the College.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Wounded.

Surgeon A. E. PANTER, R.N.

ARMY.

Killed in Action.

CAPTAIN W. R. ASPINALL, M.C., A.A.M.C.

Captain W. R. Aspinall, M.C., Australian Army Medical Corps, whose death in action was recorded in our issue of August 18th, was born in 1893. He was the youngest son of the Rev. A. A. Aspinall, M.A., and was educated at the Scots College, Sydney, of which his father had been principal for twenty-one years, and won his college blue for cricket, football, and tennis. He studied medicine at Sydney University, and obtained the M.B. Ch.M. degrees with honours in 1915. Whilst at the university he was captain of the first football team, and gained his blue for interstate football. Before taking up his commission in the A.A.M.C. he was a resident medical officer at the Sydney Hospital. His three brothers, all medical men, have seen active service with the Australian Imperial Force.

Died of Wounds.

CAPTAIN W. J. EVANS, R.A.M.C.

Captain William Jones Evans, R.A.M.C., was reported as having died of wounds, in the casualty list published on September 26th. He was educated at Pontyvaun County School, at Cardiff Medical School, and at University College Hospital, London, took the diplomas of M.R.C.S. and L.R.C.P.Lond. early in 1916, and immediately afterwards entered the R.A.M.C. as a temporary lieutenant, becoming captain after a year's service. He was attached to the Gloucestershire Regiment when killed. He was the only son of the Rev. W. Evans, Baptist minister, Risca.

CAPTAIN F. HARDIE, R.A.M.C.(T.F.)

Captain Frederick Hardie, R.A.M.C.(T.F.), died of wounds on September 20th. He was the only son of Mrs. Hardie, of 12, Dalhousie Terrace, Edinburgh, was educated at Edinburgh University, and after graduating as M.B. and Ch.B. in 1900, went into practice at Southampton. He joined the Third Wessex (Portsmouth) Field Ambulance as lieutenant on October 28th, 1914, and was promoted to captain six months later. After nine months' field training in England he went to France, where he proved himself a keen and efficient field ambulance officer. He was mortally wounded by a shell just after returning from an arduous tour of duty behind the trenches, and died the same day. His commanding officer in a letter speaks of his constant cheeriness and the regard in which he was held by all ranks, and adds: "During his two years' active service he has done good work under many dangerous and trying conditions." Captain Hardie leaves a widow and two children.

Wounded.

Captain R. G. Abercrombie, R.A.M.C. (temporary).
 Captain F. Black, R.A.M.C. (temporary).
 Captain F. G. Flood, R.A.M.C. (temporary).
 Captain F. R. H. Laverick, R.A.M.C. (temporary).
 Captain G. A. Macfarland, R.A.M.C. (temporary).
 Captain M. McNiff, R.A.M.C. (temporary).
 Captain A. C. Ransford, R.A.M.C.(T.F.).
 Captain D. L. Tate, R.A.M.C. (temporary).
 Captain J. StG. Wilson, R.A.M.C. (temporary).
 Lieutenant G. H. Adam, R.A.M.C. (temporary).
 Lieutenant C. O. Bodman, R.A.M.C. (temporary).
 Lieutenant H. Dearden, R.A.M.C. (temporary).
 Lieutenant C. B. Simpson, R.A.M.C. (temporary).
 Sister M. Clarke, Q.A.I.M.N.S.R.
 Sister J. A. Herbert, T.F.N.S.
 Sister A. Redpath, Q.A.I.M.N.S.R.
 Sister M. B. Thomson, Q.A.I.M.N.S.R.
 Sister M. J. Weaver, Q.A.I.M.N.S.R.

Died on Service.

TEMPORARY LIEUTENANT R. F. HILEY, I.M.S.

Temporary Lieutenant Richard Farrar Hiley, I.M.S., died at Saidapur, Coorg, on March 20th, 1917. He was educated at Cambridge, where he graduated B.A. in 1884, and at St. Thomas's Hospital, and took the diplomas of L.S.A. in 1888, M.R.C.S. in 1900, and L.M.S.S.A. in 1909. After serving as medical officer of the Desaguedel Valle de Mexico, and of the Pyrites Company, Newfoundland, he became medical officer of the Planters' Medical Fund in South Coorg, Southern India. He left this post to take a temporary commission as lieutenant in the I.M.S. on January 27th, 1916, and after completing a year's service, during which he served in Mesopotamia, he resigned in bad health on January 27th, 1917, and returned to Coorg, where he died less than two months later.

ASSISTANT SURGEON A. R. UNDERWOOD, I.S.M.D.

Fourth Class Assistant Surgeon Alexander Russell Underwood, Indian Subordinate Medical Department, was accidentally drowned in Mesopotamia on September 13th. He was the second son of Captain A. W. Underwood, of the Indian Ordnance Department, was born on December 9th, 1890, and educated at Wyggeston School, and at the Universities of Bombay and Calcutta. He entered the I.S.M.D. on April 17th, 1911, was stationed at Lucknow before the war, and had been mentioned in General Sir S. Maude's recent dispatches from Mesopotamia.

LIEUTENANT J. F. ELLIOTT, R.A.M.C.

Lieutenant John Forster Elliott, R.A.M.C., died at Rostrevor, co. Down, on September 30th, aged 50. He was the son of the late Mr. O. F. Elliott, manager of the Northern Bank, Monaghan, and was educated at Trinity College, Dublin, and at the Ledwich and Carmichael schools in that city, taking the L.R.C.P.Ire. and L.R.C.S. Ire. in 1893. After practising for a time in Manchester he went to Natal, where he held the post of medical officer of the Indian Immigration Board. Returning home he started practice at Rostrevor, and last year took a temporary commission in the R.A.M.C. He was the author of a small work, *Hints to Ship Surgeons*.

DEATHS AMONG SONS OF MEDICAL MEN.

Bailey, John Bodley, Second Lieutenant East Yorkshire Regiment, only child of Dr. J. Elford Bailey, of Beverley, killed September 21st, aged 20. He got his commission on January 2nd, 1915, was wounded in July, 1916, and subsequently transferred to the Royal Flying Corps.

Chown, Francis Jack, Second Lieutenant R.F.C., killed in an aerial fight in the battle of Menin Road, on September 20th, aged 19. He was the only son of Dr. Chown, of Townshend, near Hayle, and was educated at Temple Grove and St. Paul's School. He passed for Sandhurst, but entered the R.F.C. direct from school, in July, 1916, and got his "wings" in May, 1917, when he was appointed an instructor. He went to France on August 18th, and was posted to a scout squadron only eight days before his death.

Eakin, Robert Andrew, Captain King's Shropshire Light Infantry, only son of Dr. J. W. Eakin, of Trinidad, died in Netley Hospital on September 24th, 1917, of wounds received in France in October, 1914. He was born in February, 1883, and served in the South African war, gaining the Queen's medal with four clasps. He got a commission in the Lancashire Fusiliers in June, 1904, was promoted to lieutenant on October 12th, 1907, and transferred to the K.S.L.I. on May 20th, 1908, getting his company in November, 1914.

Holt, W. P., Captain Army Service Corps, son of Dr. Crawshaw Holt, of Didsbury, Manchester, killed in June, aged 23. He was educated at Aldenham School, got a commission in the 4th Company of the Manchester Brigade, A.S.C. (T.F.), on August 9th, 1914, and after serving for two years at Khartoum and at Alexandria joined the Royal Flying Corps. He went to France last May, and was killed in an aeroplane accident the following month.

Lewis, M. G. N. H., Captain Monmouthshire Regiment, only son of the late Dr. David T. Lewis, London, killed in France, September 17th, aged 24. He was educated at Shrewsbury, when the war began was in the National Provincial Bank at Abergavenny, enlisted in August, 1914, got his first commission on October 21st, 1914, and went to France in August, 1916.

Mahomed, Claude Atkinson Elly, Lieutenant Scots Guards, only son of Mr. and Mrs. George Mahomed of Bournemouth, aged 31. He was educated at Salisbury School, and became an electric light engineer in Argentina. He was killed in the advance of July 31st, near Boesinghe.

Rooney, Richard Y., Captain Royal Engineers, died of wounds received on September 19th. He was the youngest son of Colonel J. P. Rooney, A.M.S., formerly P.M.O., Scottish Command. He joined the Argyll and Sutherland Highlanders as lieutenant in 1914, and on attaining the rank of captain was transferred to the Royal Engineers. His elder brother.

Major G. C. Rooney, R.M.L.I., H.M.S. *Queen Mary*, was killed in the battle of Jutland on May 31st, 1916.

Thomas, Owen, Captain Yeomanry, and Assistant Provost Marshal, son of the late Dr. Thomas, of Southampton and of Harefield, Bitterne, Hants, died suddenly on active service on August 21st, aged 37. He served in the South African Constabulary, in the South African war, gaining the medal, and in Gallipoli in 1915. He got a commission as captain in the Welsh Horse on August 30th, 1914, and had recently been mentioned in dispatches.

Tobin-Willis, Jack, Lieutenant R.F.C., killed in action in France on August 17th, aged 21. He was the only son of Dr. and Mrs. Willis, nephew of Dr. Tobin of Ilkeston, Derbyshire, and grandson of the late James Tobin of Tincurry House, Cahir, co. Tipperary. He was educated at St. Cuthbert's, Newcastle-on-Tyne, and afterwards by the Benedictines at Donai Abbey. He was a law student and an undergraduate of London University. He went to France in January, 1915, with a commission in the A.S.C., and was posted to the 1st Cavalry Division. Six months ago he volunteered for the Royal Flying Corps, and trained as gunner and observer. Having won his "wings" in France, he became more especially engaged in observation of German artillery as well as in aerial fighting.

West, H. M. P., Captain Northumberland Fusiliers, only son of Dr. West, of Jesmond, Newcastle-on-Tyne, killed September 20th. His first commission was dated November 13th, 1914.

White, Lewis Smith, Captain Royal Flying Corps, youngest son of Dr. E. White, of Bath, killed in a flying accident at Westgate on September 28th. He was flying instructor at that camp, and had been decorated with the Military Cross at the recent investiture on September 26th.

Workman, Charles Service, M.C., Lieutenant Cameronians (Scottish Rifles) and Royal Flying Corps, younger son of Dr. Charles Workman, of Glasgow, died of wounds on July 20th, aged 20. He got a commission in the 5th (Territorial) Battalion of his regiment on October 24th, 1914.

MEDICAL STUDENT.

Hughes-Jones, Kenneth H., Captain Rifle Brigade, fourth son of Mr. L. Hughes-Jones, of Chevet Hay, Wrexham, killed September 20th. He was educated at Bradfield School, where he gained a scholarship, and was in the O.T.C., and entered Guy's Hospital with an entrance scholarship in 1915. He enlisted in December, 1915, got his commission in July, 1916, and went to the front in October.

The initials of Captain J. K. Small, R.A.M.C. (temporary) were incorrectly printed in the list of officers wounded published in our issue of September 15th, p. 371.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SUPPLEMENT to the *London Gazette* issued on September 26th contains a further list of awards for gallantry and distinguished service in the field. The acts for which the decorations have been awarded will be announced in the *London Gazette* as early as practicable. The following medical officers are included in the list:

Bar to D.S.O.

Major James Samuel Yeaman Rogers, D.S.O., R.A.M.C. (D.S.O. gazetted January 14th, 1916).

D.S.O.

Major (temporary Lieut.-Colonel) Edward Charles Montgomery-Smith, R.A.M.C.

Captain (acting Lieut.-Colonel) John Darling Bowie, R.A.M.C.

Captain Gwelym David Watkins, R.A.M.C.

Temporary Captains: David Lees, M.B., R.A.M.C.; Ivan Clarkson Maclean, M.C., R.A.M.C.; John Boyd Orr, M.C., M.B., R.A.M.C.; Hubert Arnold Pallant, M.C., R.A.M.C.

Bar to Military Cross.

Captains William Barnsley Allen, V.C., M.C., R.A.M.C. (M.C. gazetted September 26th, 1916); Wilfred McFarlane, M.C., M.B., R.A.M.C. (M.C. gazetted December 11th, 1916); Hugh Roger Partridge, M.C., R.A.M.C. (M.C. gazetted October 20th, 1916); John Dover Proud, M.C., R.A.M.C. (S.R.) (M.C. gazetted June 18th, 1917).

Temporary Captain Robert Inkerman Harris, M.C., R.A.M.C. (M.C. gazetted November 14th, 1916).

Temporary Lieutenant (temporary Captain) Lancelot Gerard Bourdillon, D.S.O., M.C., R.A.M.C. (M.C. gazetted January 14th, 1916).

Military Cross.

Captains Cuthbert Delaval S. Agassiz, M.B., R.A.M.C.; Arthur Cyril Bateman, R.A.M.C. (S.R.); Kenneth Biggs, R.A.M.C. (S.R.); Ribton Gore Blair, M.B., R.A.M.C. (S.R.); Francis Dawson Blandy, M.D., R.A.M.C.; Thomas Frederick

Corkhill, R.A.M.C. (S.R.); William Ernest FitzGerald, M.B., R.A.M.C.; James Canute Gordon Glassford, A.A.M.C.; Herbert Myer Goldstein, N.Z.M.C.; James Alexander Paterson, M.B., R.A.M.C.; Gilbert William Rogers, M.B., R.A.M.C.; James Ellis Rusby, R.A.M.C. (S.R.); Herbert Mather Spoor, M.B., R.A.M.C.; Robert Alexander Stark, M.B., R.A.M.C.; John Stephenson, R.A.M.C. (S.R.); William Howard Edwin Stewart, R.A.M.C.

Temporary Captains: George Min Adam, M.B., R.A.M.C.; Stanley James A. Beale, M.B., R.A.M.C.; Geoffrey Andrew Bird, M.B., R.A.M.C.; Clarence Albert Brisco, R.A.M.C.; William Thomson Brown, M.B., R.A.M.C.; Wilfrid Thomas Channing-Pearce, R.A.M.C.; Francis Bernard Chavasse, R.A.M.C.; Victor Lindley Connolly, R.A.M.C.; George Theodore Cregan, M.B., R.A.M.C.; Douglas StClair Creighton, M.D., R.A.M.C.; Eric Payton Dark, M.B., R.A.M.C.; Harold Benjamin Day, R.A.M.C.; James Walker Dorling, M.B., R.A.M.C.; Robert Stuart Gibson, M.B., R.A.M.C.; John Charles Boileau Grant, M.B., R.A.M.C.; Norman Grellier, R.A.M.C.; Frederick Harris, R.A.M.C.; Howard Havelock Hepburn, M.D., R.A.M.C.; James Hill, M.B., R.A.M.C.; Archibald Forbes Laird, R.A.M.C.; George Edwin Lindsay, M.B., R.A.M.C.; Clement Richard MacLeod, R.A.M.C.; Daniel McVicker, R.A.M.C.; Jerome Ivo O'Sullivan, R.A.M.C.; William Hilton Parry, M.B., R.A.M.C.; Frederick Tavinor Rees, R.A.M.C.; Douglas Swan Robertson, M.B., R.A.M.C.; Alexander Hugh Dickson Smith, R.A.M.C.; James Anstruther Smith, M.B., R.A.M.C.; Thomas James Logan Thompson, M.B., R.A.M.C.; Edward Archibald Walker, M.D., R.A.M.C.; Hubert Francis Wilson, M.B., R.A.M.C.

Temporary Lieutenants: Gerald Woodforde Harrison, R.A.M.C.; Reginald Gordon Hill, M.B., R.A.M.C.; William Johnstone Isbister, R.A.M.C.; Ronald Sinclair Kennedy, R.A.M.C. (S. Lances R.); John Peter Ryan, R.A.M.C.; Thomas Charles Dalrymple Watt, M.B., R.A.M.C.

Sergeant-Major A. P. Hatt, R.A.M.C., has also received the Military Cross.

FOREIGN DECORATIONS.

The President of the French Republic has awarded the *Croix de Guerre* to Major (temporary Lieut.-Colonel) L. J. M. Deas, M.B., F.R.C.S., I.M.S., and temporary Captain A. L. George, R.A.M.C., in recognition of distinguished services rendered during the course of the campaign.

NOTES.

PENSIONS FOR DEPENDANTS OF I.M.S. OFFICERS.

THE India Office announces that the provisions of Part II of the Royal Pensions Warrant of August 1st, 1917, apply to the pensions of the widows, children, or dependants of officers of the Indian army, Indian Medical Service (permanent and temporary), and Indian Army Reserve of Officers, deceased in consequence of the present war. The benefits of the Royal Warrant, where it differs from previous warrants, have effect from April 1st, 1917. Pensions granted to widows and children of officers of the above classes have been, or will be, reviewed by the India Office, and, where necessary, readjusted without application, but in the following cases application is necessary: (1) Claims to education allowance; (2) claims of relatives of deceased officers other than widows and children. The application should bear a reference to any previous correspondence, and should be made in writing to the Under Secretary of State for India, Military Department, India Office, London, S.W. 1.

PENSIONS MEDICAL REFEREES.

It is announced that the Ministry of Pensions has now completed arrangements for the selection and appointment of medical referees, whose duty it will be to give expert advice both to the local War Pensions Committees, and to the Ministry in regard to discharged disabled men. The medical referees will examine disabled men and certify as to the institutional or other treatment suitable for each case, while their advice will be sought in respect to the physical capacity of men whom it is proposed to train for particular trades, or who apply for "alternative" pensions based upon their former earnings and their present earning powers. In the selection of medical men for appointment as referees the Minister of Pensions will be advised by a small committee consisting of representatives of the medical profession and of the public departments most concerned.

CAPTAIN JOSEPH ELLIS MILNE, R.A.M.C., of Aberdeen, who was killed in France on February 22nd, 1917, left estate valued at £16,792.

England and Wales.

CONFERENCE OF MEDICAL WOMEN IN MANCHESTER.

At a conference of the Medical Women's Federation held on September 29th at the Manchester University Union the proposal to establish a Ministry of Health was discussed. Dr. Jane Walker, who presided, expressed the view that such a Ministry was really coming, and was greatly needed. No doubt the most attractive proposal was to set up an entirely new body, but that would mean a great deal of undesirable dislocation. On the whole, she thought it would be best to rename the Local Government Board, and equip it with all the functions of a health administration. Had there been a Ministry of Health there would have been no need for the formation of a Ministry of Pensions, since the functions of the latter would automatically have been absorbed by the former. Any scheme for a Ministry of Health must as a primary condition comprise the public health sections of the Board of Education, the Insurance Commission, and the Local Government Board, each department retaining its other sections intact. Dr. Catherine Chisholm spoke particularly of the position of general practitioners under any scheme of reconstruction. She dwelt on the great services rendered by this section of the medical profession, but argued that while the demand for the general practitioner was still large the calling became less attractive every year. Lady Barrett spoke especially on infant welfare, pointing out that the control of infant mortality could not be discussed apart from the care of the mother. Such duties together with housing and the provision of sanitation, must come within the functions of a Ministry of Health. After full discussion it was resolved to refer to the local associations for reconsideration—first, the question of the advisability of establishing a Ministry of Health; and, secondly, in the event of a Ministry of Health being established, the question of which departments most urgently needed to be dealt with by such authority. In a further discussion, Dr. Ethel Cassie urged the importance of antenatal clinics, closely connected with which were prematernity wards, home visiting, the feeding of expectant mothers, and instruction at schools for mothers. Dr. Helen Fairley spoke of the need for ensuring the speedy attendance of a medical man in the case of mothers attended by certain midwives, since the death of the infant was often due to the midwife's failure to appreciate what was taking place. Dr. Ethel Stacy thought the general practitioner was not in a position to undertake specialized infant welfare work. He tended to become a kind of sorting officer. She urged that general practitioners should take up post-graduate work and that infant welfare centres should arrange for the attendance and help of the general practitioner. Dr. Esther Carling, in a paper on tuberculosis, said the Insurance Act had begun at the wrong end and the conditions were now in a state of chaos. The committees which provided the money were on the brink of bankruptcy and there was no unification of treatment. Dr. Margaret Sharp, in discussing venereal disease, said that the clinics at Bradford had now got as many cases as they could deal with. The mass of the patients were of the fairly respectable type, and most of them had been sent by private doctors.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

King Edward's Hospital Fund for London has published its statistical report on the ordinary expenditure of 109 London hospitals for the year 1916, prepared from the published accounts of these institutions and from returns made to the Fund. The introduction states that during the year upwards of 153,500 in-patients were admitted, while more than a million and a quarter patients attended at the several out-patient departments. The in-patients included 27,328 naval and military patients treated by understanding with the authorities. They represent 25 per cent. of the total average number of occupied beds, an increase of 4 per cent. as compared with 1915. A significant note states that 1,215 of the beds occupied by naval and military patients were taken from those previously used by civilians. On the other hand, the receipts from the authorities in aid of the expenditure on naval and military patients amounted to scarcely more than 14 per cent. of the total ordinary expenditure of the hospitals. The

growing cost of maintenance is shown by the fact that the total ordinary expenditure of the hospitals was more than 13 per cent. greater than in 1913. The cost of working at hospitals has been affected by the rise of prices, by the shortage of workers both skilled and unskilled, and by changes in the number of occupied beds due to the provision of accommodation for wounded soldiers. The last-named cause operates very unequally, sometimes decreasing the number of beds occupied and increasing the cost per bed, and sometimes increasing the number and decreasing the cost; in either case it often acts in a manner quite outside the control of the hospital management. For these reasons the customary calculations based on comparisons with average cost have again been omitted from the report. The prefatory note ends with a warning that conclusions must not be hastily drawn from the statistical tables, since these profess to give only the materials for a comparison of outlay, and to stimulate inquiry into the causes of high cost and the control of expenditure.

Scotland.

A MINISTRY OF HEALTH.

The Secretary for Scotland, Mr. Robert Munro, K.C., M.P., received on September 24th a deputation from the Scottish branch of the Society of Medical Officers of Health, consisting of Dr. Alexander Robb (Midlothian), Dr. A. Campbell Munro (Renfrewshire), Dr. A. K. Chalmers (Glasgow), Dr. Thomas Adam (Stirlingshire), Dr. G. Pratt Yule (Fife), Dr. J. Hunter (Motherwell), Dr. John Guy (Edinburgh), and Dr. Ralph Picken (Glasgow). The object of the deputation was to submit two resolutions passed by the society. The first was that the present system of health administration is inadequate and inefficient, that unification and expansion are needed, and that for effective reform all departments dealing with disease both in relation to prevention and treatment should be placed under one authority. The second was that the unit for public health administration should not be smaller than that adopted under the National Insurance Act, namely, areas with not less than 20,000 inhabitants. Dr. Robb, in introducing the deputation, said that they were of opinion that public health administration should be thoroughly reconstructed. Dr. Chalmers said that they desired to approach the question less from the point of view of which department was best equipped to carry on the work than from that of the public requirements. He also touched on the difficult question of whether there should be one Ministry of Health or three. Mr. Munro, in the course of a very guarded reply, balanced various considerations, but let fall nothing which could commit either himself or the Government to any definite line of action.

A GLASGOW CHILD WELFARE CLINIC.

A new building erected as a children's clinic in connexion with the Elder Cottage Hospital, Govan, was opened last week by the Duchess of Montrose; together with the hospital and nurses' training home it will be included as a unit in the child welfare scheme of the Glasgow public health authority. Antenatal cases are to be dealt with at the training home and children up to 5 years of age in the new clinic, which includes a large waiting-room, weighing and dressing rooms, a general consulting-room, a dental consulting-room, and a dispensary. Dr. John Macintyre, the chairman of the House Committee, who presided at the ceremony, said that the evil to be combated in order to improve the condition of the children in large centres of industrial activity was stupendous, but the means now being taken gave grounds for hope. The Duchess of Montrose said that the nurses from the clinic would follow up the cases at home with the co-operation of the lady health visitors of the district. Dr. Edward McConnell, speaking for the Child Welfare Committee of the Corporation, and Dr. A. K. Chalmers, Medical Officer of Health for Glasgow, both delivered addresses emphasizing the importance of child welfare work, and afterwards Sir George T. Beatson struck a hopeful note, saying that a great deal had been done within the past sixteen years to diminish infantile mortality, which had been reduced from

148 per 1,000 in 1900 to 83 per 1,000 last year. If so much had been done by spreading knowledge, by improving housing, and by safeguarding food, it was justifiable to look forward hopefully to the future.

Correspondence.

EPSOM COLLEGE WAR MEMORIAL.

SIR,—Two informal meetings of Old Epsomians have been held regarding the question of raising a memorial to old Epsom boys who have fought and fallen in this war. It was decided that a meeting was to be held at the offices of the College, 37, Soho Square, W.C., at 4 p.m. on Friday, October 12th. It is intended to get an expression of opinion at that meeting as to whether such a memorial shall be raised, what form such a memorial should take, and how should the money for it be raised. A treasurer and secretaries for this memorial should be appointed. The head master of the school, the Rev. W. Barton, and myself are acting as secretaries until the proper appointments are made. As addresses are so uncertain it seemed desirable to notify old Epsom boys of this meeting through the press. Will all who can, come to the meeting; and will those who cannot come, express their views in a letter addressed to me?—I am, etc.,

37, Harley Street, London, W.1.
Sept. 28th.

E. M. CORNER.

RECURRENCE OF ADENOIDS AND TONSILS.

SIR,—Owing to absence from London, I have only just seen the interesting lecture of Dr. Douglas Guthrie in your issue of the 15th inst., and the timely criticism in last week's JOURNAL by my friend Sir StClair Thomson of the statement that there is no such thing as recurrence after a thorough removal. I think most operators of long experience and sufficient clinical opportunity in large centres of population will readily admit a 5 per cent. margin of possible recurrence even after the most careful removal. In this connexion it may be well to recall the important series of papers on diseases of the upper air passages by my old friend Sir Felix Semon in this JOURNAL, beginning on November 2nd, 1901, in which the question of the proportion of what may be called inevitable recurrence was incidentally discussed. For my own part I cannot agree with Dr. Guthrie that even the most carefully constructed curette will, even in most cases, thoroughly remove "adenoids." From its nature a curette will necessarily shave them; but, though it may often even eradicate them, generally speaking, shaving is the result. A certain amount of adenoid tissue usually remains to form the smooth mosaic immediately left by this form of operation and to furnish the root-stock, so to speak, of a recurrence in favouring circumstances.

I had the advantage some twenty years ago of seeing Sir Felix Simon do some tonsil and adenoid operations, and was much impressed by the amount of care and deliberation which was allowed by the use of forceps guided by the left forefinger in the nasopharynx. Though I had previously used the curette I have invariably used forceps since that time, working from left to right, and in some cases using a specially curved instrument when the mass extended far forwards towards the choanae. When I at all use a curette it is merely for smooth shaving of the remaining surface. By this method no adenoid tissue is left to grow again like a sliced tonsil. From a long experience, including thousands of cases, I am convinced that this is the best way to guard against recurrence, and that if it should take place after this operation it must be only in those somewhat rare cases referred to by Sir StClair Thomson in which there is an inveterate hereditary tendency to the production of this tissue.

I should, perhaps, add that I reverse the order of the operation as commonly practised nowadays. Having first made sure of a thorough removal of the "adenoids" the throat is swabbed out and then the tonsils are removed—in children usually only by guillotine with some previous dissection when necessary. The patient is then turned into the semiprone position with the face downwards over a receiver and "drained." This operation has proved invariably successful as regards the immediate result of the operation in over 20,000 cases, and owing to the somewhat

peculiar circumstances of my hospital *clientèle* I have been able to follow up the histories of hundreds of them, some to the point of operating on their children. Amongst those so followed I can remember no case of recurrence, though I, of course, admit the wide margin of possibilities.

There is another point in Dr. Guthrie's lecture which hardly receives the prominence it deserves. I refer to the case of a boy of 7 who had neither adenoids nor tonsils, but a much-deflected septum. It is not in my experience to find any child of this age with such a septum without some adenoids, and usually, where no operation has been done, a considerable quantity. I take it for granted that Dr. Guthrie, in this instance, did not "avoid palpating the nasopharynx," and therefore willingly admit what he says, but only as a very rare experience. I should like to draw attention to the tendency of almost all children in whom a necessary operation for adenoids has been postponed after the fourth year to develop a more or less deflected septum nasi. I have seen it even earlier, but this seems a fair average time of incidence. I have collected a large number of cases to illustrate, amongst others, this point in a paper now in preparation. Amongst the conclusions suggested by this material one of the most prominent is that after the fourth year a deflected septum is the commonest structural cause of persistent mouth breathing even after a thorough removal of adenoids and tonsils, and furnishes another strong reason for their earliest possible removal after definite symptoms have been noted.—I am, etc.,

London, W., Sept. 28th.

JAMES DONELAN.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—I have carefully read Dr. Brackenbury's letter in the JOURNAL of September 29th, and while thanking him for the evident trouble he has taken with his exposition, I confess that I am still unable to see any difference in essentials between the proposed method of remuneration and that in operation with respect to temporary residents, with the one exception which I clearly mentioned in my letter of September 1st—namely, the making up of the pool to the necessary amount to meet the bills by the Treasury.

In support of my view I quote the letter, dated June 27th, 1917, addressed by Dr. Brackenbury's own Committee (the Insurance Acts Committee) to the Commissioners. In the second paragraph appear the following words: "I am instructed to inform you that the Committee . . . accepts . . . the proposal . . . whereby medical practitioners will be remunerated in respect of disabled soldiers and sailors discharged in future on the attendance basis at the same rates as temporary residents."

Dr. Brackenbury now admits that these detailed proposals were never before a conference, and I on my side am ready to agree with him that the whole question about these men has been before the profession for a long time. I may say it has been anxiously in my mind ever since the war began. But the point is, as Dr. A. S. Downton points out, "that Panel Committees, and through them panel practitioners, had no opportunity of considering those regulations before they were actually enforced."

The resolutions passed by the Conferences in 1915 and 1916—that the British Medical Association should be authorized to voice the opinion of Local Medical and Panel Committees as a whole in central negotiations—clearly meant that the British Medical Association (having asked for and received the opinions of such committees) should act as their mouthpiece in expressing those opinions to the Commissioners; and should take all necessary steps to have them carried into effect. Surely Dr. Brackenbury does not mean to imply that those resolutions conferred plenary powers on the British Medical Association to agree to anything they liked on our behalf? That would be equivalent to saying that the Panel Committees had passed a resolution saying that the British Medical Association should think for them!

I must here, in fairness to the British Medical Association, say that in my opinion the practitioners of the country, taken as a whole, have at times behaved in such a manner as to lead one to suppose that they had decided to let others do their thinking for them; and the apparent apathy of the British Medical Association on some occasions may well have been due to their total inability to

obtain a clear mandate from practitioners. Nothing is more calculated to fetter the activities of representatives than the apathy and indecision of their constituents. But I do hope and believe that the Conference on October 18th will furnish a mandate in such clear and unmistakable terms that there will be no option but to obey it.

I am delighted to hear that Dr. Brackenbury is going to move a resolution demanding a 10s. capitation fee, and I can promise him plenty of support from this part of the country. I am glad, also, to receive his assurance that the Insurance Acts Committee made this suggestion three months before we did. I grudge them none of the credit due to them.—I am, etc.,

Gloucester, Sept. 30th.

J. A. BELL.

SIR,—Dr. Brackenbury has made a mistake in his letter in the *JOURNAL* of September 29th, when he says I fail to keep the question of the remuneration for attendance on insured persons separate from that of increased payment for discharged disabled men. I deal with the latter question in the first two paragraphs of my letter in the *JOURNAL* of September 15th, whilst the third paragraph asks Panel Committees to vote for general increased panel remuneration. All the medical men I have spoken to are aware of the distinction between the two classes, but many were not aware of the exact nature of the terms of attendance on the disabled men, and expected full payment of the fees quoted and no check on the number of visits and attendances.

Dr. Brackenbury, in an earlier paragraph of his letter, writes: "All attendances, however many, will be paid for at this rate without any deduction whatever." Are we to understand that there is to be no system of checking excessive attendance, and that the Treasury will pay the full 95 per cent. of all accounts sent in?

I must apologize for not being quite accurate, and also, when I read the third paragraph again, not quite courteous to Dr. Brackenbury, in my reference to the last Panel Conference. (I hope Dr. Brackenbury has apologized to the Kent Panel Committee for the speech he made on a certain resolution sent by that Committee.) My inaccuracy was caused by my remembrance of Dr. Brackenbury's speech rather than of the exact wording of the motion, for several of the members of the Conference said to me afterwards that although the resolution stated we had a claim to increased remuneration, there was evidently never the slightest intention of pushing that claim.

My 25 per cent. refers to increase of the schedule of fees for attendance on temporary residents; in the first paragraph I quote 2s. 6d. for a visit, 2s. for a consultation, and the next paragraph begins: "This rate of remuneration . . . ; it ought to be increased by at least 25 per cent." But I really mean 25 per cent. The Insurance Acts Committee "thinks" there should be a generally increased remuneration of 35 per cent., which will probably mean an increase of from 10 to 15 per cent.; but it seems to me that the profession will demand an increase of nearer 50 per cent.—namely, from 7s. to 10s. per insured person. Further, that the 10s. will be an all-round capitation grant to include all returned sailors and soldiers.

Dr. Brackenbury in his letter writes that he moved a resolution at the last Conference, not as Chairman of the Insurance Acts Committee but as the representative of the Panel Committee which had given notice of it. I have for long had an intention of writing to you on this dual position held by Dr. Brackenbury. I think it is wrong, because it is difficult at times, when he is addressing the Conference, to decide whether he speaks as the chairman or as the representative. I hope that he and those who are calling the Conference together will consider this point of view and let him attend as Chairman of the Insurance Acts Committee, whilst his Panel Committee will appoint some one else as the representative.—I am, etc.,

Burnley, Sept. 29th.

JAMES GARDNER.

SIR,—A variety of criticisms of the new Regulations for Medical Benefit for Invalided Seamen and Soldiers, 1917, have appeared in various medical journals, and have been circulated to Panel Committees. A careful comparison of these with the actual Regulations, and with the explanatory Memorandum 234/I.C., reveals a serious misunderstanding on the part of some of them, and the matter can therefore be approached with an unbiassed mind. Both

the Regulations and the Memorandum present a complex system, which it is to be feared few of the panel practitioners (unless they have previously made a careful study of the system of remuneration for ordinary insured persons) will thoroughly grasp. It is well, therefore, to analyse the sources and the method of payment of this money, which is to go to provide medical attention for those men who, above all others, have the claim that their country should give them the best that can be procured. If the system is such that the attendance will have to be given as a part charity, it is bad, and public opinion, once enlightened, will not permit it.

In the succeeding paragraphs quotations refer either to the Regulations or the Memorandum above. "Soldiers' means invalided seamen and soldiers. "General fund" means the ordinary medical benefit fund as actually paid after deductions for inflation of lists, etc. "Soldiers' fund" means the special fund created for paying doctors for the treatment of invalided seamen and soldiers.

For the sake of clearness we will not consider the cost of drugs, the floating 6d., and the sanatorium 6d. separately, but take the 9s. nominally allowed for medical benefit as the basis of calculation as is done in the Memorandum.

1. *Source of the Money.*—For each soldier present in a district 9s. is deducted from the general fund and paid into the soldiers' fund (Regulations, 5), but this 9s. does not correspond to the original value of the soldier in the general fund. The amount of the general fund per individual on the Insurance Committee's list is less than 9s. by 20.6 per cent. (for 1916, probably still less now). Owing to the alleged inflation of lists each name on the list is only worth 7s. 2d., therefore, for each soldier in a district the general fund is further depleted by 1s. 10d. To reduce it to an absurdity, if 80 per cent. of the insured persons on the list were invalid soldiers, the whole general fund would become the soldiers' fund, and the remaining 20 per cent. ordinary insured persons would have to be attended for nothing.

2. *Method of Payment.*—Nine shillings having been deducted from the general fund as above, we now deal with the opportunities offered to panel practitioners for recovering it.

The schedule to the Regulations gives a scale of fees. But it must be particularly noted that this scale of fees is not the scale which will be actually paid. Like the capitation fee for insured persons, it is a nominal one only. The actual payments given to panel practitioners for the treatment of the soldiers depend upon a pooling system (Regulations, 6 (1), (2)), which at once renders the whole scale uncertain and subject to deductions. The fees will certainly be *something less* than those stated in the scale. The scale itself is plain enough, and it is for practitioners to say whether they consider it an adequate one as it stands, and even if they were not themselves finding the money to meet it. So far as this area is concerned the principal fee of 2s. (that for surgery attendance), is two-thirds of the minimum fee accepted by local practitioners for friendly society work on the same lines.

But there are other points to be considered in connexion with the method of payment. Accounts (duly arranged alphabetically, Memo. 20) must be sent in within seven days of the end of the quarter (Regulations, 3 (2)). But there is absolutely no time limit for payment of these accounts. Advance payments *may* be made (Memo. 30). The balance after deductions can still be withheld indefinitely. Our experience with the ordinary fees for National Health Insurance work teaches us what to expect; those for 1916 are still unpaid. Again, the chances of panel practitioners recovering the 9s. deducted from their general fund are notably lessened by the admission of non-panel practitioners. These can share in the chances of getting the 9s., but not in the inflation of panel lists, by which panel practitioners lose 1s. 10d. on each soldier. That is to say, the whole 9s. (taken out of the general fund in respect of each soldier originally worth only 7s. 2d.) can be earned by non-panel practitioners undertaking cases without the option of recovery in these cases by panel practitioners; for each soldier treated by a non-panel man, 1s. 10d. is irretrievably lost to the panel practitioners whether the non-panel man succeeds in getting it or not.

Finally, in the Memo. great stress is laid upon two points, upon which the Commissioners seem to base the hope that the Regulations will be agreeable to the profession: (a) An Exchequer grant is mentioned (Memo. 5),

and it is stated that should the 9s. be insufficient "to meet charges upon it," Exchequer funds will be forthcoming to supply the deficiency (Memo. 6). Does this mean that by means of an Exchequer grant the practitioners' bills will be met in full? By no means; the pooling system allows for indefinite deductions upon which practitioners can have no control. It merely means that the total bills after correction (by which the nominal fees may be reduced 20 per cent. or 50 per cent.) will be met, should they exceed in the aggregate 9s. per head. But we may rest assured that the Exchequer grant (which it is to be particularly noted is not mentioned in the Regulations) will not be required. What is offered with one hand can easily, under the Regulations, be withdrawn by the other. (b) It is repeatedly stated that the whole Regulations have been drafted at the request and with the approval of "The Medical Profession" (Memo., 3, 4, 19, 29). Of this statement it can only be said that it does not coincide with the facts. Panel Committees and Local Medical Committees, which alone represent the panel practitioners, and the whole of the medical profession, were never consulted, and have never seen the Regulations until, as now, they are stated to be in force, and to form part of our agreement with the Insurance Committees (vide letters issued by Insurance Committees to all panel practitioners). This is a flagrant breach of the promise of the Insurance Commissioners in 1915 that all new Regulations should be submitted to the profession in time for discussion before coming into force, and in any case should not be brought into force during the course of any given year except in a serious and unforeseen emergency. The Insurance Acts Committee of the British Medical Association appears to have agreed to them, but it has done so without consultation with the Local Medical and Panel Committees which it professes to represent. It appears that a direct challenge has been issued by the Commissioners to panel practitioners.

If we accept these Regulations as they stand, we are not merely agreeing to a system which will mean a heavy financial loss, and endless trouble; we are allowing the National Health Insurance Commissioners to ram new regulations down our throats without discussion or protest.—I am, etc.,

J. C. LYTH,
Honorary Secretary, York Local Medical
and Panel Committee.

October 1st.

N.B.—The above letter has been endorsed by the York Local Medical and Panel Committee, whose views it expresses.

SIR,—Many letters on this subject have appeared in the JOURNAL during the last few weeks, which I have read with varying interest. It appears to me away in the far North that in the wrangle about the payment for these men there is at least one very important point which has, so far as I know, not been thought of or alluded to. Everything seems to be at sixes and sevens, and every one has his own ideas and views—whether it be that A is satisfied with the promised remuneration of 95 per cent. of the scheduled rates, or that B will have none of it but demands a 10s. or a 12s. 6d. capitation rate. Again, some men are not clear about the method by which the pool for disabled men is made up. They are up in arms because they think, or are certain, that it is to be made up out of the medical benefit fund, and that therefore it is not fair that non-insured sailors and soldiers returning to civil life should benefit at the expense of men who have been insured since the inception of the Acts. I do not think they need trouble themselves about that, since the pool is to be made up out of the army and navy fund.

The point to which I wish to draw the attention of insurance practitioners is that of the present remuneration. This consists of 6s. per head per annum paid by the societies, 6d. for domiciliary treatment, and the Treasury grant of 2s. 6d. In order to earn this grant Mr. Lloyd George demanded three *quid pro quo's*:

1. That the attendance given to insured persons should be such as would have the approval of the Commissioners.

2. That the doctors should issue the required certificates.

3. That the doctors should keep medical records of all cases.

Every one knows that the medical records were allowed to lapse in 1916, in deference to the depletion of the ranks of insurance practitioners and to ease their work. As yet the system has not been re-established. Making a simple calculation, the 2s. 6d. may be divided into three sums of 10d. each—that is, 10d. for each of the three conditions. I am not advocating the ways and doings of the Commissioners, but when they agreed to withdraw the keeping of the records no one can say that they suggested the withdrawal of the so-called 10d. for record keeping. They might have done so in a perfectly legal manner, seeing that they were getting nothing for something. May I ask practitioners to think for a moment what this 10d. means? There are, say, 14 millions of insured persons in the country, and 14 million pence amounts to nearly £600,000, which are distributed among the panel practitioners each year for doing nothing by way of earning it. In consideration of this free gift to the profession, I would counsel practitioners to cease their squabbling and accept the scheduled rate of the Regulations for attendance on disabled sailors and soldiers, who are deserving of the best doctors can give them, even though the latter should get only a dividend of 95 per cent.—I am, etc.,

Edinburgh, Oct. 3rd.

MICHAEL DEWAR.

SIR,—Would it be of any avail if the Association were to beg the Insurance Commissioners to withdraw the present regulations about discharged soldiers and reissue them in simple, plain, and unmistakable language, as it is fully proved by the letters in your and other journals that medical men do not understand them, and paragraphs in the lay press show that different meanings are read into them? Why should the phrasing of every document sent out by the Commissioners be so obscure? A gentleman on the staff informed me that no one in the office understood what was meant, and gave an explanation which I had better not repeat.—I am, etc.,

London, S.W., Sept. 29th.

JAMES HAMILTON.

THE DISCOVERER OF THE CAUSE OF SLEEPING SICKNESS.

SIR,—At last, after waiting nine years, I have induced Sir Ray Lankester to reply to one of my letters on this subject. The facts related in that letter (BRITISH MEDICAL JOURNAL, September 15th, 1917), as well as in all my previous communications, are unassailable. Sir Ray Lankester, therefore, has recourse to a few *obiter dicta* and offensive remarks, as is his wont.

In all my publications, as a matter of mere justice, I have always given the credit to Castellani:

1. "Of having first discovered the trypanosome in the cerebro-spinal fluid of sleeping sickness patients." Sir Ray Lankester states that this is true, and no one has ever denied it. I of course agree with him.

2. "Of having connected the trypanosome he discovered in the cerebro-spinal fluid with the etiology of the disease." According to Sir Ray Lankester, this is not true, as Castellani gave no importance to the trypanosome. I beg to refer again to an incident recorded in my letters to the *Times* of 1908 and 1913, which will tax Sir Ray Lankester's ingenuity to explain away. On our arrival in Entebbe, Castellani would only tell Colonel Bruce about having found the trypanosome in sleeping sickness patients *on condition that I was not informed of the fact*. Does this look as if he attributed no importance to the observation? I beg leave also to quote the following extract, taken verbatim from Report 1 of the Sleeping Sickness Commission of the Royal Society.

Report 1, entitled *Presence of Trypanosome in Sleeping Sickness*, by Aldo Castellani, M.D. On page 10 of this report Castellani says, "Influenced by my last investigations, I would suggest as a working hypothesis on which to base further investigations that sleeping sickness is due to the species of trypanosome I have found in the cerebro-spinal fluid of the patients in this disease, and that at least in the last stages there is a concomitant streptococcus infection which plays a certain part in the course of the disease."

3. "Of having first published it." This, Sir Ray Lankester says, is true, but no credit should be given to Castellani, as it was Bruce who wrote Castellani's report. Sir David Bruce certainly corrected the English of Castellani's paper, but this surely does not entitle him or any one else to claim Castellani's discovery. The Goanese

clerk who typed Castellani's report will next put in a claim for the discovery.

In this connexion I would also quote the following extract from the Royal Society's reports, and would particularly call the attention of the reader to the passage I have marked in italics, showing that Colonel Bruce evidently expected Castellani to publish the report.

Report 2, entitled *Progress Report on Sleeping Sickness in Uganda*, by Lieut.-Colonel David Bruce, F.R.S., R.A.M.C., and David Nabarro, M.D. On page 12 it states, "Dr. Castellani informed us of the work he had done, one especially interesting observation being that he had discovered trypanosomes in the cerebro-spinal fluid in 5 out of 15 cases of sleeping sickness. Dr. Castellani remained in Entebbe for three weeks after the arrival of the new Commission, and during this time he examined 29 further cases for trypanosomes, with the result that 70 per cent. were found to contain those parasites. *Dr. Castellani, we presume, has already published these results.* After his departure the Commission continued to pursue this line of work."

Lastly, I would quote a statement made by Colonel Bruce himself on page 5 of the *Further Report on Sleeping Sickness in Uganda*, and be it noted that the historical account found in this report was inserted by Bruce without my knowledge. After referring to Castellani's "most interesting discovery" which put the Commission "on the right track and led to the rapid and easy elucidation of the etiology of this hitherto mysterious disease," Colonel Bruce states: "Without the knowledge of his observation they (that is, the Commission) might have worked for months in the dark, and in truth they might even have returned to England still ignorant as to the true cause of the disease." What further evidence can Sir Ray Lankester, or any one else want, as to the great part played by Castellani in the elucidation of the etiology of sleeping sickness?

As regards myself, according to Sir Ray Lankester's ridiculous statements, I should not be entitled to any credit for the development of the discoveries, the foundations of which were so surely laid by Castellani, and for the discovery that the trypanosome of sleeping sickness is carried by a tsetse fly; my claims are "illusory," to use Sir Ray Lankester's word, and this, although I was associated with Colonel Bruce the whole time he was in Uganda, and the share of the work I did was certainly not less than that of Colonel Bruce, and the reports were joint reports. Truly, Sir Ray Lankester's mentality is of a peculiar kind.

In conclusion I should like to ask your readers to keep in mind the fact, omitted by Sir Ray Lankester in all his communications, that the Commission sent out to Uganda in February, 1903, by the Royal Society consisted of *two members only—Colonel Bruce and myself.* I am, therefore, in a unique position to know the history of the investigation.—I am, etc.,

London, W., Sept. 25th.

DAVID NABARRO.

"BARCOO ROT."

SIR,—In your issue of June 9th an article by Lieut.-Colonel C. J. Martin gives some observations on "barcoo rot." This is a very loosely applied term. The original "barcoo rot," as experienced by the older bushmen, was scurvy pure and simple. Owing to the improved conditions of living this is now practically extinct, but the younger bushmen, hearing their fathers talk of "barcoo rot," have applied the term to any superficial obstinate sore, never having seen the genuine "barcoo rot" themselves. There are two varieties: a staphylococcal infection of skin abrasions, naturally mostly on the hands, seasonal, occurring generally in the autumn; and the other is deep-seated trichophytosis of the hand.—I am, etc.,

Allora, Queensland, Aug. 5th.

FRANCIS PAIN.

THE SCABIES PROBLEM ON ACTIVE SERVICE.

SIR,—The prevention of scabies and impetigo in the army is a matter of regular inspection, early detection, isolation, and treatment by the medical officers, but it is also most essential that there should be constant and systematic inspection of those affected with these diseases, no matter what treatment may be decided upon. Orders must be carried out and discipline maintained in order to effect cures successfully and rapidly.

Sulphur vapour has been suggested as a remedy for scabies, and lately chlorine gas,¹ both of which are

troublesome irritants. Liq. calcis sulphurata or Vlemingx's lotion (quicklime 2 drachms, sulphur 4 oz., water 20 oz.) was also once in vogue, but some years ago an Army Medical Service memorandum was issued stating that much irritation was caused by this preparation, and that its curative effects were inferior, and not equal to a weak sulphur ointment properly used, and this still holds good.

Cases come before medical officers in all stages, from mild attacks of scabies to those more severe, in which eczema or impetigo and septic sores have developed and which require special treatment, so that it is impossible to adopt a hard and fast routine, or lay down any one remedy as suiting all cases. A lotion or ointment which is all right for one man may, in small quantity, cause violent irritation to another. The old-fashioned rule of thumb practice will not do. Individual idiosyncrasies must be taken into account.

The secondary impetiginous condition so frequently seen, and which necessarily makes treatment more complicated and difficult, is caused by the entrance of staphylococci and streptococci into a skin which has been irritated and excoriated by scratching and tearing with dirty nails, especially when the case has been neglected and the acarus has gained a footing all over the body, but it may also supervene when the skin has become inflamed by excessive treatment or the use of strong remedies. Therefore, it is the individuality and knowledge of the medical officer directing the treatment upon which the result depends, and consequently the keynote should be regular and skilled inspection, with treatment adapted to the various types of cases.—I am, etc.,

S. W. ALLWORTHY, M.A., M.D., D.P.H.,

Belfast, Sept. 21st.

Captain R.A.M.C.(T.C.).

SIR,—Major MacCormac's paper in the *BRITISH MEDICAL JOURNAL* of September 22nd, 1917, on the scabies problem is very instructive. One or two questions, however, suggest themselves. What actually is the evidence that blankets are the chief means of disseminating infection? Has the acarus been found on blankets? What is meant by frequent disinfection? What is the minimum percentage of Clayton sulphur vapour, and the minimum time required to kill *Acarus scabiei* and its ova on blankets, and how has this been established?

Has Major MacCormac tried dilution of the sulphur ointment in order to eliminate dermatitis and sulphur itching? Why is it considered advisable to soak a patient in grease twice daily for three days if a liquid preparation of sulphur (which soon dries, and is neither greasy nor messy) is, as he says, undoubtedly efficient? And if, as he remarks, Vlemingx's solution is particularly liable to produce dermatitis, can this objection not be excluded by dilution with water?

Finally, what are the items in the experience necessary for its satisfactory employment?

If Major MacCormac, or other person of experience, will answer these questions, he will confer a favour on many an army medical officer who at this moment is looking for guidance in the management and rapid and effective and simple and yet non-messy treatment of this *bête noire* which causes such a vast amount of ineffectiveness.—I am, etc.,

September 24th.

AN ARMY M.O.

SIR,—In connexion with the treatment of scabies by chlorine gas, the subject of a paper by Captain Clark and Captain Raper, published in the *BRITISH MEDICAL JOURNAL* on July 23th, I should like to quote an interesting case which occurred in the regiment to which I am at present attached as medical officer. About ten days ago the regimental gas officer came to me complaining of "eczema" of a fortnight's duration, due, he thought, to the irritation of the gas fumes. On examination I found his fingers, arms, and especially his buttocks and legs a mass of typical scabies spots, which he said were very itchy at night. He was the worst case of uncomplicated scabies I have seen for some time, and he assures me that, since it started, he has been several times exposed to the chlorine gas fumes in the "gas hut." He has now practically recovered under a course of sulphur baths and inunction.—I am, etc.,

J. A. C. MAGEE, M.B., B.S.,

September 6th.

Captain R.A.M.C.(T.)

¹ *BRITISH MEDICAL JOURNAL*, July 28th, 1917.

CEREBRO-SPINAL FEVER AND ITS TREATMENT.

SIR,—With reference to the leading article on cerebro-spinal fever and its treatment published on September 22nd in your journal, in which you reviewed the work of Dr. Fairley and myself, I would like to furnish some additional information gained by myself in 1916. I do so in order to emphasize the extreme importance of pushing antimeningococcal serum by intravenous and subcutaneous administration as well as the ordinary intrathecal medication. The value of intravenous serum has not received the acknowledgement to which it is entitled, and a wider use of this method will assuredly lead to a lessening in the mortality.

The following figures were incorporated in an article published in the *Australian Medical Journal* of April 21st this year, and are based on 201 cases treated by myself during the year 1916 at the Alfred Hospital, Melbourne. Including hopeless and elderly cases the gross mortality was 38 per cent., compared with 253 cases and 49 per cent. mortality in 1915.

The following table shows the results of the various lines of treatment adopted in 1916, and speaks for itself:

Treatment.	Gross Figures.			Excluding Hopeless Cases and those of 35 years of age and over.		
	Cured.	Died.	Mortality.	Cured.	Died.	Mortality.
Lumbar puncture only (all mild cases)	16	6	27.2 %	13	4	23.5 %
Antimeningococcal serum intrathecally only (mostly mild cases)	14	10	41.6 %	14	4	22.2 %
A.M.S.* intrathecally and subcutaneously (all grades of cases)	71	50	41.3 %	62	23	27 %
A.M.S. intrathecally, subcutaneously, and intravenously (all severe cases)	17	11	39.2 %	14	3	17.6 %

* A.M.S. = Antimeningococcal serum.

Comment on the above is unnecessary, except to state that in the corrected column recoveries as well as deaths in those over 35 years of age have been excluded.

As regards dosage, it has been my practice to give 100 c.cm. of serum intravenously and repeat daily for two or three days if necessary, 50 or 60 c.cm. being sufficient for these subsequent doses. In addition, 300 c.cm. is given as the initial dose subcutaneously and daily doses of 200 c.cm. repeated for two or three days if necessary.—I am, etc.,

Weymouth, Sept. 30th.

C. ALWYN STEWART, M.D. Melb.

THE MENINGOCOCCUS.

SIR,—In a footnote¹ Dr. E. C. Hort explains that he does not propose to include the meningococcus among the ascomycetes in the newer mycology, but gives reasons for interning it among the hemiascomycetes which suggest that he is devoid of humour.

In any case, without wasting valuable space, I may be permitted to point out that it takes more than preconceived opinion and an oil immersion lens to demonstrate the existence of an endospore. Nevertheless, if present in his aldermanic meningococci, this ought to be within the power of any intelligent worker with a bacteriological microscope in ordinary daylight. And when Dr. E. C. Hort proves that he has an endospore to deal with and not an assumption his paper will belong to the literature of science.—I am, etc.,

London, W., Sept. 23rd.

ROBERT CRAIK.

TREATMENT OF VINCENT'S ANGINA.

SIR,—I have been much interested in the division of opinion between Captain Emrys-Roberts and Dr. Frank Taylor on the treatment of Vincent's angina. I observe that while the former eulogizes a mixture of hydrogen peroxide, ipecacuanha, and glycerin, the latter says the proper treatment is a "topical application of salvarsan."

With all due respect for these opinions, may I venture to say that a "topical" application of ordinary tincture of

iodine twice a day has cleared up four cases I have seen since July, 1915, in a few days. I would suggest that if Captain Emrys-Roberts oxidizes the spirilla out of existence and Dr. F. Taylor poisons him as rapidly with arsenic, free iodine may be equally fatal, as it is held to have a specific action on another well-known spirilla—that is, if form and constitution vary together.

Of the four cases I have seen, the first occurred in July, 1915, in a sergeant who was sent into the Seaford Military Hospital with a shallow grey excavated ulcer of the posterior fauces and a diagnosis of syphilis; as the swab showed only the familiar fusiform bacillus and spirilla, he was treated with tincture of iodine and recovered within a few days.

The other three cases have been seen during the last eighteen months in my private practice; all occurred in young women; all simulated diphtheria, and were treated with antitoxin (2,000 units) as a prophylactic; in two of them there was a very definite yellowish-white membrane partly involving the uvula; the other was complicated by pneumococci. Under similar treatment all were well in a few days.

It may be of interest, though for all I know it is common knowledge, that in these cases (I can only speak of the four I have seen) there is no albumin in the urine or loss of knee jerks.—I am, etc.,

Clebury Mortimer, Sept. 29th.

L. SCARGILL.

SIR,—I have been interested in following the correspondence of Major F. W. Bowman and also that of Dr. F. E. Taylor and Captain W. H. McKinstry, with reference to the treatment of Vincent's angina. On March 3rd, 1911, I had several cases which had occurred in a large residential boys' school, brought to me by the medical officer for diagnosis and advice. Deep scrapings from the cases were submitted to bacteriological examination, and upon verification thus I strongly advised the medical attendant to use freely hydrogen peroxide solution, and at the same time to have destroyed the tooth-brushes which were in use, and which I suspected were causing conveyance of infection from the original cases to others. The outbreak under the measures adopted was limited, there being only the same number of subsequent cases discovered on further investigation. I attribute the good results entirely to the liberal use of fresh solution of hydrogen peroxide, which was used as a gargle and mouth wash by all the scholars. The discovered cases were thoroughly swabbed three or four times a day.

I am writing, as I agree with Major Bowman, but would point out that the main virtue lies in the hydrogen peroxide. It is a non-toxic remedy that can be used quite lavishly, whereas the treatment by salvarsan is expensive and unsatisfactory for general use.—I am, etc.,

G. CLARK TROTTER, M.D., D.P.H., F.R.S.E.,
Paisley, Oct. 1st. Medical Officer of Health.

Obituary.

DAVID CHARLES REES, M.R.C.S., L.R.C.P.,

DISTRICT SURGEON AND PORT MEDICAL OFFICER, PORT ELIZABETH.

In the *Medical Journal of South Africa*, June, 1917, the death of Dr. D. C. Rees from typhus fever, in his fiftieth year, is announced. Dr. Rees was educated at Charing Cross Hospital Medical School, and after obtaining the diploma of the Conjoint Board in 1895 went out to Nigeria with General Lugard's Frontier Force. He went up the Niger, saw service there, and gained considerable experience in the diseases of the country. On his return, the London School of Tropical Medicine was just being opened, and Sir Patrick Manson (then Dr. Manson) was fortunate enough to secure his services as the first Superintendent (or as it was then called Medical Tutor) of the School. The first session opened on October 1st, 1899, and Dr. Rees was responsible for organizing the lectures and other details of the course. So well did he do this that the general scheme adopted by him has held, with additions of course, till the present day. Dr. Rees was an able teacher, and had a happy knack of interesting the pioneer students in the laboratory work, most of which was, of course, quite new.

In the summer of 1901, during the vacation, he visited

the experimental house, set up by the School in the Roman Campagna for the malarial experiment, and he stayed there for several days with Drs. Sambon and Low, the experimenters. He then returned to the School for the fourth session, and worked in London till the end of the year; finally, to the sorrow of all his fellow teachers, giving up his appointment to take up the very important post of district surgeon and port health officer at Port Elizabeth, Natal. Here the opportunity of combating plague and small-pox presented itself, and ably dealing with these, Dr. Rees made a name for himself in this line. That he should have died of typhus, a disease he was trying to stamp out, is very sad—a fate, however, which others who have gone before have also shared. After taking up his residence in South Africa, he did not have the time or opportunity to come much to London, but he visited it on the occasion of his marriage, and again three or four years ago, when he visited the School of Tropical Medicine and renewed his old associations with that institution.

There is little doubt that if Dr. Rees had stuck to tropical medicine, he would have made a name for himself in that line of research. Before leaving for Africa, he wrote on tropical subjects to the journals, and these contributions were always well written and carefully thought out. Work in Port Elizabeth did not allow him apparently to keep up his literary efforts. Dr. Rees has left a widow and two children to mourn his loss. To them the London School of Tropical Medicine and all its teachers who knew and were associated with him offer sincere sympathy.

Universities and Colleges.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

THE two Goldsmid entrance exhibitions, offered annually for competition in September, have been awarded to Mr. H. L. Heimann and Mr. V. R. Khanolkar, both of University College, London.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examinations indicated:

M.B., CH.B.—*Medical Jurisprudence and Public Health (New Regulations)*.—J. D. Arthur, A. S. Bisset, A. Black, D. C. Bowie, W. G. Burns, M. J. Cahalane, H. A. Cochrane, H. L. Coulthard, E. M. E. Cumming, A. M. Davidson, J. Donald, J. C. Dow, A. B. S. Drysdale, W. Edgar, D. Finlayson, G. O. Grant, J. S. M. L. Gray, J. A. Hamilton, W. R. D. Hamilton, J. G. Harrower, A. Henderson, H. J. Hollis, M. Hyman, J. Irving, R. P. Jack, J. A. Jenkins, J. P. Kilby, A. C. Lindsay, J. Lipschitz, A. J. Macartney, D. MacCorm, T. McGowan, J. A. C. MacGregor, J. W. Mackay, D. Maclean, W. S. L. McLeish, J. Macleod, W. M. Linden, A. W. M'Rorie, J. M. Melvin, W. Napier, B. F. Niblock, J. Nicol, I. L. Oluwole, N. B. Peacock, J. W. Peden, R. J. Peters, J. B. Potter, A. Riddell, J. M. Ritchie, W. Scotland, R. P. Smith, J. C. Vaughan, W. A. Walker, J. A. Walls, H. Wands, G. M. Wishart, W. Young, Ellen D. Anderson, Grace Chatterton, Mary B. Gillespie, Alison M. Hunter, Elizabeth C. Loudon, Mary J. Macdonald, Isabella Q. M'Fadzean, Maud E. D. MacKinnon, Margaret G. M'Vey, Margaret M. Morton, Elizabeth B. Y. Paterson, Margaret M. C. Steedman. (*Old Regulations*).—C. O. Anderson, P. Macdiarmid, J. S. Neighan, J. A. O'Connor, D. Stewart, K. Young, Lillias B. Hardie.

* Passed with distinction.

FOURTH (FINAL) M.B., CH.B.—Maud C. Cairney, B. W. H. Fergus, J. B. D. Galbraith, K. J. A. Gillanders, W. M. Kerr, F. R. Lubovius, Elizabeth C. M'Hattie, J. Macleod, Alice J. Marshall, Margaret M. Morton, A. Riddell, S. M. Riddick, I. M. Robertson, Jessie N. Robertson, J. A. Stewart, J. T. Taylor, W. H. Wallace, J. P. White.

Medical News.

It is announced that Major John Utting, R.A.M.C. (T.F.), will be the next Lord Mayor of Liverpool.

A LECTURE on sanitary work in the army will be delivered at University College, London, by Major Arthur J. Martin on Thursday, November 1st, at 5.30 p.m. The chair will be taken by the Hon. Sir John McCall, M.D.

DR. MARCUS PATERSON, Medical Director of the King Edward VII Welsh National Memorial Association for the Prevention of Consumption, has resigned that appointment owing, we regret to learn, to continued ill health.

A MEETING of the Medico-Legal Society will be held at 11, Chandos Street, Cavendish Square, W.1, on Tuesday, October 16th, at 8.30 p.m., when an address will be given

by the president, Sir Samuel Evans, and a discussion on the Criminal Law Amendment Bill (1917) will be opened by Dr. F. J. Smith.

THE Automobile Association and Motor Union, Whitcomb Street, Coventry Street, W., has been in communication with the Ministry of Munitions regarding the use of coal gas on cars. The reply of the Ministry is to the effect that coal gas is not regarded as a petrol substitute, and that the Home Office is being consulted regarding its unrestricted use.

THE following entrance scholarships have been awarded at Guy's Hospital Medical School: Senior Science Scholarships for university students, £75, R. Gainsborough, Magdalen College, Oxford; Junior Science Scholarship, £120, A. T. Rogers, Preliminary Science Class, Guy's Hospital. Scholarships in Arts: £50, G. R. M. Apsey, King's School, Canterbury; £50, C. H. C. Toussaint, St. Bees School.

PROFESSOR H. G. PLIMMER, F.R.S., will give a course of about ten lectures on tropical hygiene on Tuesday during the first half of the winter session. The lectures will be given in the Botany Department of the Imperial College of Science and Technology, Prince Consort Road, South Kensington. Further particulars can be obtained on application to the Registrar of the College. The fee for the course is £1. The first lecture, which will be given on Tuesday next, October 9th, at 4 p.m., will deal with general principles and the classification of disease causes; the second with the definition and nature of infectious diseases; the third, fourth, and fifth with directly infectious diseases, especially enteric fever. The remaining lectures will deal with other diseases prevalent in the tropics, the last two being concerned with general advice as to the maintenance of health in the tropics and the treatment of minor complaints and injuries.

A CONFERENCE of representatives of friendly societies and other organizations connected with national insurance was held at the Central Hall, Westminster, on September 29th, in order to discuss the question of the setting up of a Ministry of Health. Mr. Kingsley Wood, who took the chair, stated that during the Parliamentary recess proposals had been formulated, and a bill drafted for the establishment of a Ministry of Health, at the instance of the great national insurance organizations. He claimed that this was the first definite scheme that had been put before the nation, that it was an urgent war measure, and that it must be put into force before demobilization. The bill provides for central organization only. Under it a Minister of Cabinet rank would be assisted by a board of health containing representatives of the medical profession, of the local health services, of national insurance interests, and of labour.

NOTICES.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 423, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Attitology, Westrand, London*; telephone, 2651, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2650, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2654, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

THE CANADIAN ARMY MEDICAL SERVICE.

BY

SURGEON-GENERAL J. T. FOTHERINGHAM, C.M.G.,

DIRECTOR OF MEDICAL SERVICES, INVALIDS, C.E.F.; LATE
A.D.M.S. SECOND CANADIAN DIVISION.

The adage, "Cast thy bread upon the waters, and thou shalt find it after many days," had never truer exemplification than in the relations found existing in this great war of all the ages between the R.A.M.C. and the Canadian A.M.C. The latter is the lusty progeny of the former, and well pleased that the physique and lineaments of the parent can be seen in the child. In all matters of present-day organization, equipment, and even uniform, the two services are closely homologated and interchangeable. But in spirit, and sympathy, and attainments, and just and generous emulation their relations are more fraternal than parental.

During the somewhat troubled years which followed in British North America after the rebellion of the American colonies the British troops who helped, as in the war of 1812-1815, to safeguard the feeble settlements of Nova Scotia, Lower Canada, and Upper Canada, had their medical officers—army doctors as they were known. Not a few of these well-trained men left the service to settle down to practice in Canada, and in most cases at once secured a commanding professional position in the new community. Their superior education and good social position gave to many of them great influence with the authorities, especially in Upper Canada—now Ontario—and this influence was always exerted in favour of sound legislation on all matters pertaining to education, both general and professional. The provinces were thus from the outset, to a very large extent, protected from the evils of free and unlicensed medical practice, from which the United States are only now with much effort and delay beginning to shake themselves free. British ideals in both teaching and practice have in the main prevailed everywhere in Canada, the precedent and example of the medical legislation in the older provinces being closely followed in the newer as they were organized, so that all the medical faculties in Canada have always drawn their inspiration, neither from American nor German sources, but from the great schools of London, Edinburgh, and Dublin.

With this heritage, nothing could be more natural and legitimate than that the Canadian Army Medical Service should both give and get, in this time of sore trial for all British hopes and ideals, absolute mutual co-operation and goodwill in its relations with the Royal Army Medical Corps and Service. The opportunity of comradeship and common service in the stricken field and in the cause of empire and civilization is keenly realized and most highly prized by all ranks.

The intimacy between the two services is evidenced by the circumstance that many scores of Canadian graduates hold temporary commissions in the R.A.M.C., and the value of their services is freely acknowledged by their fellow officers. Furthermore, the Canadian laboratory man has been given his chance and has made good in both British and Canadian laboratories in the field, and the friendly rivalry and hearty good comradeship of their work has gone far to make permanent for all time the good relations which are and can be based only upon mutual respect. One dreams of the day when the degree or licence of any reputable faculty in the empire may run and be recognized as valid in all the parts of the empire.

A summary of the activities of the C.A.M.C. may be made under the three topics:

1. Preventive medicine;
2. Clinical progress in medicine and surgery; and
3. Laboratory and research work.

PREVENTIVE MEDICINE.

With reference to preventive medicine the two outstanding features of the situation are:

- (a) Preventive inoculation.
- (b) Sanitary control in the field.

(a) Preventive Inoculation.

On the Western front, where most of the Canadian medical troops have been employed, this has been mainly against the typhoid group, small-pox, and tetanus.

The percentage of inoculated men as regards the first two runs very high, practically 100 per cent., as the conscientious objector is not recognized by the Canadian authorities and legitimate means have been found for overcoming the objections of the very few who were at first disinclined to submit.

Antitetanic serum has been administered in all main dressing stations to all wounded, and latterly to trench foot cases, at the time of their admission, the dose being entered on field medical card and in the admission and discharge book. The dose has been, as a rule, 1,500 units. The serum has been to a large extent, but not exclusively, obtained from the Canadian Red Cross Society, and is that manufactured in the laboratories of the University of Toronto through the thoughtful provision of a wealthy benefactor there. The regular source of supply through the advanced dépôts of medical stores has also been drawn upon. Comparisons and results are not available as yet, but there is no doubt in the minds of all in a position to judge that, as a preventive measure, the procedure is proved to be indispensable.

The same remark holds true, if possible more positively, with regard to antityphoid inoculation. When regard is had to the practical absence of true typhoid and to the extraordinarily low incidence of the other diseases of the enteric group on the one hand, and to the universal contamination of the water supply by the colon group on the other, one may truly say that a new chapter may now be written in the history of military medicine, and that the world at large owes to Sir William Leishman and the R.A.M.C. a debt which it can never repay; and it should not be forgotten that the millions of men now in the war zone and far from their accustomed strains of enteric infection represent, without inoculation, virgin soil for the ravages of the disease.

Small-pox has been practically non-existent among the Canadian troops, as each man signs in his attestation papers an undertaking to undergo vaccination, which is universal.

Dysentery has occurred in a slight, sporadic form, but not as either epidemic or endemic. Such cases, even though only suspected, are sent to a special hospital in each army direct from the field ambulance, admitting by motor ambulance convoy car.

(b) Sanitary Control in the Field.

The two important parts of this many-sided problem are water control and disposal of waste. The organization necessary is briefly as follows:

1. Battalion and unit sanitary sections, specially detailed and trained by unit medical officers and employed under their direction. Responsibility rests with each O.C. for his own lines, the M.O. acting as adviser.

2. Divisional sanitary section under a specially qualified medical officer, who is also divisional sanitary officer, under command of A.D.M.S. of Division, reporting to him, and employing the other ranks of his unit as inspectors over the whole area occupied by the Division with reference to water supply, disposal of waste, and conservancy arrangements of every sort.

The opinion has been steadily growing that for the semi-siege type of warfare so far prevailing on the Western front, too frequent moves of these divisional sanitary sections detract seriously from their usefulness, and that they should, within limits, be made more permanently responsible for the areas with which they have become familiar, after the manner in which town majors and camp commandants are employed.

With respect to the protection of the water supply, in addition to the supervision maintained by the divisional sanitary sections, which is good, the Canadian corps has in action a water patrol. This patrol places a second check upon the chlorination of water.

Experience has shown that a water which gives a good reaction for the presence of free chlorine half an hour after the addition of chloride of lime can be considered a safe water. The requisite amount—1 gram (1 scoop), or more, to 110 gallons (the capacity of the water-cart)—is gauged by testing at frequent intervals during the day, the amount varying according to the organic content of the water. Small cases are supplied to the British Expeditionary Force, whereby sanitary or regimental medical officers may so test water and establish the amount of chloride of lime necessary to produce sterilization. Mobile laboratories are

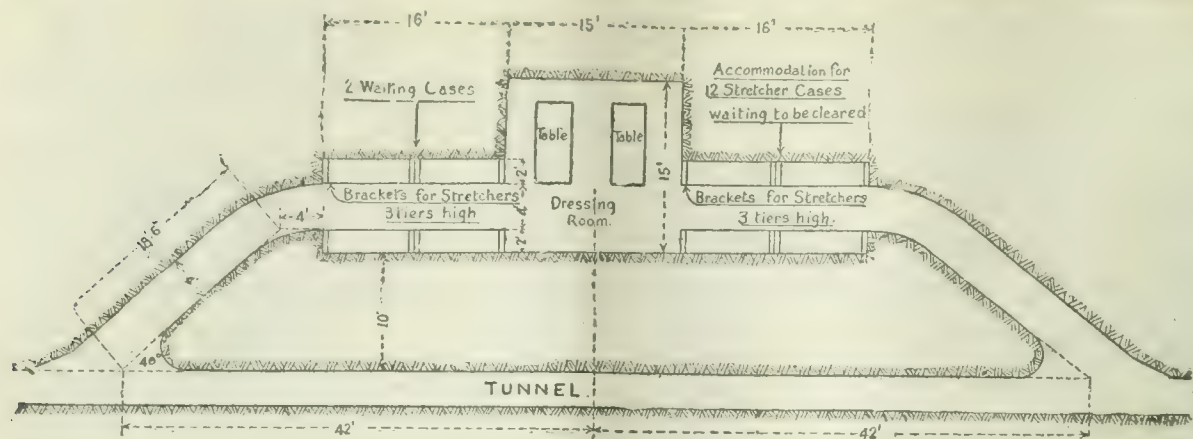

FIG. 1.—Regimental Aid Posts in a Tunnel. Accommodation, 24 cases.

available to examine and give any information on request. Muddy water must first be filtered, otherwise sterilization will not be complete, the chloride of lime failing to penetrate to the centre of particles of mud.

Water patrols, covering a Canadian corps area, are in charge of an officer under the "Q" Branch. A survey is made, maps prepared, and information collected. The corps area is then subdivided into patrol sections, each section being patrolled by one N.C.O. and five men (permanent base). The duties of these patrols are as follows:

- (a) To see that rivers, streams, ponds, wells, and springs are not polluted.
- (b) To see that no washing and no watering of horses are done at any but authorized points.
- (c) To see that no material connected with the corps water system is destroyed or removed without corps or divisional orders.
- (d) To visit daily each of the water tanks, stand-pipes, etc., where water carts are filled, collecting the daily report from the "divisional control" in charge.

Divisions are responsible that all orders regarding chlorination and "water details" are carried out, and also all instructions, such as those mentioned in paragraph (b). Any unit not complying with instructions regarding water supply is reported by the water patrols to the water patrol officer, but this does not relieve divisions from their responsibility for seeing that all instructions are carried out. Where a unit is reported to the water patrol officer a report is forwarded to the division concerned. Should the same unit be reported a second time, a report is forwarded to corps head quarters. Men belonging to, or attached to, the divisional sanitary sections are detailed as "water controls" by the O.C. sanitary sections for all authorized supplies in the divisional area. These water controls keep a "daily tank report" in triplicate, which sets forth the condition of carts drawing water, condition of lime, etc. A copy of these reports is forwarded daily to the divisional sanitary officer, one copy to water patrol officer, and one copy is retained as record by the water control. The divisional sanitary officer is responsible that the necessary steps are taken to prevent a recurrence. The O.C. water patrols summarize these daily tank reports once a week; a copy of this is sent to the D.D.M.S. A record is thus kept.

Other matters pertaining to the water supply are also reported to the D.D.M.S., and thus the medical services work in conjunction with the other branches to maintain as adequate and good a supply of drinking water as possible.

The incidence of water-borne diseases in the Canadian corps has been low, and it may be said has only occasioned anxiety when conditions were such as to interfere with, or prevent, the maintenance of those measures which have been indicated above.

Reference should be made to the very important topic of baths and laundries. In most British divisions it is understood that these establishments are under the control and administration of the A.D.M.S. for the "A and Q" branch of the staff. In the Canadian divisions the practice has been to relieve the medical service of this

responsibility and to place in charge a capable business man who is an officer seconded from his unit to the staff of the division. This has given excellent results, and would seem to be less wasteful of the special training of the medical officers, though close co-operation always exists between the A.D.M.S. and the officer in charge of baths and laundries through the A.A. and Q.M.G. The Foden-Thresh lorry disinfecter, for instance, which is on charge to the sanitary section and under the control of the A.D.M.S., is kept in operation at the divisional baths, where the men exchange their soiled clothing for fresh. Ordnance by arrangement makes issue of socks and underwear through the baths officer.

CLINICAL PROGRESS IN MEDICINE AND SURGERY.

The barest reference alone is possible to so wide a subject; a few topics of interest have been selected.

1. Injuries and Diseases of the Lung.

In a general way we have come to a set method of treating wounds of the lung, which usually reach the base hospital not earlier than the fifth day after infliction. Gun-shot wounds rarely, shell wounds frequently, are complicated. Haemothorax is usually demonstrable, and the history of haemoptysis is generally present. The rapidity with which blood is spat up after wounding depends on whether the upper or lower part of the lung is wounded, the haemorrhage being most prompt in the case of the former. Fever is usually present in the earlier days, often disappearing by the sixth or seventh day. When the fever continues we draw off blood from the pleura for the purpose of culture; such cultures usually prove sterile. As a usual thing we draw off by aspiration the blood about the tenth day; sometimes the blood so drawn off is replaced in a few days by effusion, so that subsequent aspirations may need to be made. The blood so drawn off is sometimes replaced by oxygen, the outflow of blood and the inflow of oxygen being made through separate needles at the same time. Of late we have not felt so keenly the necessity for the use of oxygen; our idea was that the replacement allowed a less chance of disturbance of the bulk of the lung, with consequent haemorrhage. An uncomplicated case is fit to travel, we judge, about the thirteenth or fourteenth day. The possibility of seasickness and vomiting is the chief reason against allowing cases to travel at an earlier date, as the repair of the lung wound seems to be relatively slow.

With shell wounds of the lung, and in cases where the foreign body remains in the chest cavity, no set method of treatment is possible. The x rays and the fluoroscopic screen are used to the fullest extent in all these cases; a certain small percentage of patients with foreign body are found amenable to early operation with removal. The relative infrequency of infection of the pleural blood is remarkable. I have personally seen only two cases of gas infection of the pleural blood, both of which recovered. A number of other infections by large bacilli, which might have been gas bacilli, but were not certainly so, have been treated as empyema and drained, and, so far as we know, with recovery in all cases.

In a winter such as 1916-17, there was a great prevalence of infection of the respiratory tract, including

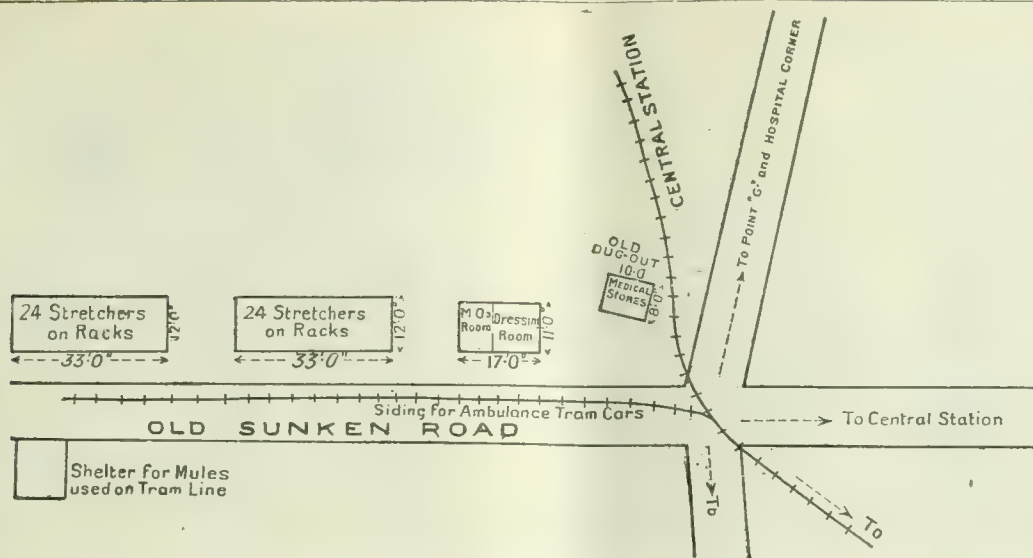

FIG. 2.—Advanced Dressing Station. Accommodation, 40 cases. This dressing station is situated in an old sunken road, and is fragment-proof. A siding has been placed in front of the station for hospital tram-cars, and a shelter has been built in the cut bank for the mules used in hauling tram-cars.

pneumonia, but it is remarkable how little prevalent lobar pneumonia has been. Severe cases of bronchitis, tracheitis, and laryngitis are common, and loss of the speaking voice is very often seen. It is difficult to distinguish mild bronchopneumonia from severe cases of bronchitis, and the presence of pneumococcus is in no sense diagnostic, as most cases show it to be present. The diagnosis has to be made on clinical grounds, and most frequently a high degree of physical disturbance, continued high fever, and the presence of blood streaks, blood or rose colour in the sputum, is used to determine the diagnosis in favour of bronchopneumonia.

A tendency to extension of the disease from one part of the lung to another at different times in the course of the malady is remarkable, so that sometimes patients are ill for weeks, with apparent extensions of the disease; the final chart of such a patient looks like a typhoid fever chart: so true is this, that in many cases we have been compelled to make agglutination tests for typhoid and paratyphoid fever, with almost constantly negative results. The absence of sunny, clear weather in winter in the northern parts of France seems to be responsible for the slow convalescence of many patients suffering from disease of the respiratory tract.

2. Continued Fevers (or "P.U.O." Cases).

Considering the cases of continued fever (or "pyrexia of unknown origin") coming to the hospital, it becomes necessary to divide them into the constituent diseases—namely, typhoid and paratyphoid fevers, so-called trench fever, and other less specific infections. Since the whole army is inoculated, the clinician is no longer able to determine on clinical grounds whether a case of continued fever be typhoid, paratyphoid, or another. The classical signs of enlarged palpable spleen, rose spots, etc., are too often absent. A dirty tongue implies gastro-intestinal disturbances but is in no wise specific. The old-fashioned Widal test is useless because it is positive by reason of inoculation. It therefore becomes necessary to make a quantitative agglutination test, which is done in series; this is done at intervals of not less than four days, and the positive diagnosis of typhoid or paratyphoid "A" or "B" may be possible by observing that there is an agglutination curve and not a stable agglutination line. From this it will be inferred that a diagnosis is sometimes made by a quantitative fall in agglutination power as well as by a rise, the fall or rise depending upon the phase in agglutination power which the blood shows at the time it is taken. No longer is the typical typhoid temperature chart to be seen. Regular, more or less continued fever, or even an acutely relapsing fever is to be seen; patients belonging to this group show very frequently myalgic pains, pains in the neck, pains in the thighs, pains in the shin bones, so that a diagnosis of the so-called trench fever upon clinical grounds becomes as difficult as a diagnosis of typhoid and paratyphoid fever. All the cases admitted into one base hospital during a certain period last winter with the pro-

visional diagnosis of pyrexia of unknown origin—that is to say, cases which were clinically transient pyrexias with no symptoms beyond the elevation of temperature and malaise—were examined bacteriologically, and it was demonstrated that 68 per cent. were typhoid or paratyphoid. Blood cultures and examinations of the stools for typhoid and paratyphoid fever were singularly useless. During the winter 150 cases suspected of typhoid or paratyphoid, whose stools were examined three times in succession, gave no positive result on any occasion.

3. Methods of Localizing Foreign Bodies.

A large percentage of the work done in an operating room of a base hospital in war time consists in the removal of foreign bodies. It is essential that this should be done with the least possible amount of traumatism, and this means that the position of the foreign body should be definitely known before the operator begins to work. The localization of these foreign bodies becomes therefore almost an art in itself, and the development of that art—if one may so call it—in the course of this war would be perfectly amazing to a civil surgeon. It is proposed, therefore, to give as briefly as possible, an account of the different methods used to locate accurately any foreign body.

For foreign bodies of known dimensions—for example, rifle bullets and shrapnel balls—a Canadian radiographer, Captain A. Howard Pirie, has devised a very ingenious scale, based upon the fact that the shadow of the foreign body increases in size as the plate is removed farther from the body. Suppose, then, the plate to be in contact with the skin, all that one has to do is to measure the size of the skiagram of the foreign body, and compare it with the scale, which will at once indicate the depth from the skin surface of the foreign body. A reference to the cross section atlas will then at once give one the position of the foreign body.

The Mackenzie Davidson method, by triangulation, of localizing the depth of a foreign body from a mark, placed previously upon the skin, is in constant use for all foreign bodies, such as pieces of shell, which are of unknown size.

If there is reason to believe, after measuring the depth of the foreign body and comparing it with the atlas, that the foreign body is in the thorax or the abdomen, a stereoscopic view is then taken and the location of the body is easily determined by looking into the adjustable stereoscopic apparatus.

As aids in the operating-room, we place first the large electro-magnet bearing the name of Bergonié of Paris. By its use can be determined the exact position of all electro-magnetic substances, and, fortunately, German bullets are electro-magnetic, whilst the English and French bullets are not. Even when these bodies are deeply situated, and their vibration cannot readily be made out by the hand, it can easily be heard by the stethoscope, placed on the skin opposite the electro-magnet. A sound, very like a steam-boat whistle, indicates the nearest point to the foreign

body, and the skin is marked at that point. In the case of non-magnetic foreign bodies, such as lead, brass, and nickel, or in the case where a magnetic foreign body is embedded in bone, and therefore cannot vibrate, we have recourse to the use of the telephone probe or, rather, forceps. This is of great assistance in locating the foreign body, either in the soft tissues or in the bone, and enables us to extract it with a minimum of damage to the tissues. In other cases, again, when the foreign body will not vibrate, or has possibly changed its position in the soft parts since the *x*-ray picture was taken (and this is notably so with foreign bodies in joints), we operate under the fluoroscopic screen.

It should be borne in mind that practically all the stationary and general hospitals sent by Canada have come from the medical faculties of the universities. A list of these it would not at the present juncture be wise perhaps to publish, but the fact that each one includes in its personnel the selected specialists and teachers in all branches of medicine and surgery from every medical faculty in the country, ensured from the outset a very high standard of professional efficiency. In addition, effective military administration has in most cases been secured, as in most of the universities there were medical men of military experience, both in the militia and in the South African war, and in the Canadian permanent service.

It is no improper divulging of official secrets to say that, both in the Mediterranean area and in France, the highest army medical authorities state that they have found these Canadian units second to none in the whole service. Their facilities for good service, too, are enhanced by the possession in several instances of large funds subscribed by the friends of their universities at home for additions to their equipment and supplies.

LABORATORY AND RESEARCH WORK.

The third main topic suggested at the outset of this article was laboratory and research work. Again, figures and statistics may not be given, and in any case could be as yet only partial. But valuable work has been done by Canadian workers, both in Canadian mobile laboratories and in collaboration in British units, in Britain, in France, and in the Mediterranean.

An enormous volume of work has been done also as part of the daily routine of the general and stationary hospitals, which requires time for the making of generalizations. Special researches of which one has heard have been made upon continued fevers, pyrexias of unknown origin, nephritis, trench fever, stomatitis, meningitis, and epidemic jaundice.

DENTAL SERVICES.

No account of the work of the C.A.M.C. would be adequate which failed to recognize the good work of the dental officers.

The dental profession in Canada is entirely distinct from the medical in respect of both training and control. There are separate Acts of Parliament for each of the professions in all the provinces. It may be that these circumstances underlay the decision of the late Minister of Militia to establish a separate Canadian Army Dental Corps. Members of the dental corps are posted one to each field ambulance in the field, and to each casualty clearing station and stationary and general hospital. In addition, there is a corps dental laboratory, where artificial dentures are made and repaired with very little loss of time or delay, such as was the case when there was no laboratory nearer than the base in France. The loss of military time from dental causes has been reduced to a minimum.

Apart from the value of their professional services to the troops at the front, which cannot be overstated, the dental officers with field ambulances take their full share of military duty in their units, on the same footing as the medical officers, and have thus still further proved their indispensability.

In France the dental service has been placed completely under the medical service, as it was realized that only one channel would be permitted for which a man might, for reasons connected with health, be allowed to escape duty. The arrangement has been completely effective and satisfactory to both dental and medical officers.

The thanks of the writer are due for their collaboration in the production of this article to various officers, and among them:

Lieutenant-Colonel A. P. Bazin, O.C. — Canadian Field Ambulance.

Lieutenant-Colonel F. S. L. Ford, C.M.G., A.D.M.S., — Canadian Division.

Lieutenant-Colonel John McCrae, Lieutenant-Colonel J. M. Elder, — Canadian General Hospital.

Major A. C. Rankin, D.D.M.S. Staff, Canadian Corps.

Major J. S. Jenkins, D.A.D.M.S., — Canadian Division.

ON THE ETIOLOGY OF TRENCH FEVER.

(A Preliminary Communication.)

BY

ALWIN M. PAPPENHEIMER, CAPTAIN, M.O.R.C.,

H. N. VERMILYE, 1ST LIEUTENANT, M.O.R.C.,

AND

SERGEANT J. H. MUELLER, U.S. ARMY.

(From the Pathological Laboratory of a General Hospital, B.E.F., France.)

The following observations bearing upon the etiology of trench fever are presented at this time because of the importance of this disease from a military viewpoint, and the desirability of having other workers confirm or refute our findings while material for the study of the disease is available in abundance.

Since our work is incomplete in many particulars, we shall at this time present merely a brief note of our experience, reserving a full publication for a later date. The literature has been available to us only in abstract form, but having no information that similar organisms have been described in connexion with the disease, we shall withhold a discussion of the work of others in this field for a later publication.

I. The Occurrence of an Organism in the Blood of Trench Fever Cases.

On June 26th, 1917, while examining a blood smear from Pte. B., a typical case of trench fever, there were found great numbers of small, circular or slightly oval, bluish-purple bodies lying upon the blood cells, or free in the plasma. They were distinctly outlined, often somewhat paler in the centre, and with a minute, intensely stained granule of pigment or chromatin at the periphery. The size of these bodies varied somewhat, averaging about one-fifth or one-sixth the diameter of a red blood cell, or approximately 1 to 1.5 microns. Not infrequently two or even several of them were found lying upon a single red corpuscle. They were not present within the leucocytes.

Since this first observation, a systematic study of blood smears of cases of trench fever admitted to the hospital has been made. Bodies of identical appearance have been found in nine cases, over 150 patients having been examined, some of them repeatedly. In some of these a few fairly typical forms have been found after long search, but in the nine cases referred to the bodies were extremely numerous, and assumed the form described. Their appearance in numbers in the circulating blood appears to be exceptional and transitory. For example, in one case (R.) a smear obtained at 3.30 p.m. showed innumerable typical forms; in smears taken at 9 p.m. none was found after prolonged search. Our records are not sufficiently complete to determine whether the appearance of the bodies in the blood coincides with febrile paroxysms and the exacerbation of the clinical symptoms. It is our impression that such is the case, although we have repeatedly failed to find the bodies during a pyrexial attack.

For the staining of the bodies Wright's, Giemsa's, and Leishman's stains have all been found satisfactory. After fixation of the films in bichloride-alcohol or Zenker's fluid the bodies stain more intensely than after fixation in methyl alcohol. Care has been taken to eliminate the possibility that the bodies observed might be artefacts. The stains have been diluted with freshly distilled water, and many controls prepared with the identical stains have been studied. The films in some of the positive cases were made on cover-glasses which had been boiled in nitric acid, so that the possibility that we are dealing with contaminating bodies on the glass seems remote.

FIG. 1.—Pte. S. Blood smear; methyl-alcohol fixation; Giemsa stain. Three blood cells containing typical bodies with peripheral granule. A group of blood platelets shown for comparison.

FIG. 2.—Section of muscle; Zenker fixation; Giemsa stain. A group of organisms scattered about the adventitia of small blood vessel.

FIG. 3.—Pte. G. Nine-day culture on slant agar of excised periosteal tissue. Note clouding of media about tissue fragments and condensation water. A. Control; B. Culture.

II. The Occurrence of Similar Organisms in Periosteum and Fascia.

With the voluntary consent of the patients small fragments of periosteum, fascia, and muscle tissue have been excised under general anaesthesia from the tibial region of nine cases showing marked local tenderness. The tissue was fixed in alcohol, Zenker's fluid, and formalin and stained with haematoxylin, Wright's and Giemsa's stains. A portion of the tissue in each case was reserved for cultural experiments, which are described below.

Bodies similar to those found in the blood smears are present in considerable numbers in the periosteum and fascia. They show a somewhat less clearly defined structure and a greater variation in size, the individuals ranging from a minute granule to a discoid body as large as a blood platelet. They are quite intensely stained in Wright and Giemsa preparations, with a somewhat more purple tinge than those found in blood films. A peripheral granule can be made out in some of the larger forms, but is not seen in the smaller bodies.

As regards their distribution in the tissue, they are found in loose aggregations about the adventitia of the smaller blood vessels, or scattered sparsely amongst the collagen fibrils. A few typical forms have been seen also within the small nerves, lying between the medullated fibres. They appear to be practically absent in the muscle tissue proper, only occasional isolated bodies being found.

They appear to produce no degenerative changes in the tissue, and to call forth no inflammatory reaction. Although most cells are abundant, and their granules resemble in their staining reaction the organisms described, the variation in size and the occurrence of large aggregations and single bodies at a distance from any nucleus enables one to distinguish between organisms and mast cell granules.

III. The Isolation of the Organism in Cultures from Excised Tissue.

The fragments of periosteum, fascia, and muscle excised from nine cases under strict asepsis were cut into smaller pieces and implanted directly into the condensation water of meat infusion agar slants. Apart from a few tubes showing easily recognizable bacterial contamination, no visible surface growth occurred. There developed, however, after forty-eight hours, a faint clouding of the medium in the vicinity of the condensation water, or in some tubes where the fragment of tissue was later withdrawn to the upper part of the slant above the condensation water; the opacity developed also about the tissue. After continued incubation at 37° C. the cloudiness extended

and increased, until after three weeks a large part of the agar became opaque. This progressive clouding of the medium has been found to be a typical and constant phenomenon, and is due to the growth of the organisms through the substance of the medium. This can be shown by examining smears obtained from cylinders of agar removed with a capillary pipette, or more convincingly by fixing discs of agar in Zenker's fluid and finding the organisms in the stained sections scattered through the agar.

The condensation water after twenty-four hours shows an increasing number of organisms in the hanging drop. These appear as moderately refractile granular or discoid bodies, with an active Brownian motion, but no evident amoeboid activity. They may form a uniform suspension, giving a distinct turbidity to the condensation water, or may be aggregated into smaller and larger clumps. Often they appear as sharply contoured rings in which, by careful focussing, it is possible to distinguish a single refractile granule, either in the centre or at the periphery.

Stained smears from the agar and condensation water have shown a puzzling variety of form and stain. Often the presence of the agar seems to prevent the permeation of the stain, so that the bodies appear as clear faintly bluish or purplish rings about which there is a condensation of the stained ground substance. In other cases the bodies are more deeply stained, and resemble closely those found in sections of periosteal tissue and blood smears. Sections of the tissue fragment after several days' incubation show conclusively that a multiplication of the organism has occurred on the surface of the tissue. In such sections the finer structure of the bodies was very distinctly shown, the central pale area and the peripheral granule being easily seen. Forms were found which were interpreted as indicating division. The discs appear to become oval, then bacillary in form, assuming the shape of a short, plump rod with rounded ends. The more deeply stained chromatin (?) accumulates at the poles, leaving an unstained clear space in the centre, through which presumably division occurs. Many diploid forms, with the deeply stained granule at opposite poles, were found, and interpreted as having undergone binary transverse fission.

In several of the cultures forms were encountered which suggested a different cycle of development, or possibly an involutional change. The small bodies became surrounded by a broad, unstained, sharply limited capsule. The central mass then appeared to increase in size, being still surrounded by a capsule, until the entire body became almost as large as a red corpuscle. Fragmentation of this central

* We are greatly indebted to Lieutenant W. F. Cunningham, M.O.R.C., for his co-operation in these experiments.

mass into five or six somewhat irregular and often rod-shaped bodies appeared to follow, and finally a further subdivision into numerous small granules, each surrounded by a clear capsule. With the rupture of the original limiting capsule these small bodies which seem to form the starting-point of the cycle are again set free.

We have not as yet been able to follow these changes in the living organisms, and are unwilling to interpret them as indicating sporulation until further studies have been made. The appearances, however, are suggestive, especially in view of the forms seen in the intestinal tract of the louse, reference to which will be made later.

Transplants have been made from the condensation water upon the following media: hydrocele-agar, dextrose, lactose, saccharose, maltose and mannite broth, lactose-bile broth and Loeffler's blood serum. In none of these media has a growth of the organism been obtained. A transplant, however, made upon human citrated blood broth after one week developed an increasing turbidity, and examination of fresh and stained preparations showed typical organisms in great abundance.

The original cultures from periosteal muscle tissues have also been transplanted to tubes containing sterile human tissue obtained at autopsy, but with varying success. The experiments are being continued, but so far we have not obtained regularly a growth in the second generation. We have attempted, without success, to substitute sterile rat connective tissue and muscle.

IV. Culture from the Circulating Blood.

In two cases we have succeeded in cultivating the organism directly from the circulating blood. A small amount—less than 1 c.cm.—of citrated blood was poured into agar tubes containing sterile human periosteal tissue obtained at autopsy. Growth occurred slowly, but showed the same characteristic clouding of the media that was found in the periosteal and fascial cultures.

Two other blood cultures obtained at the same time from cases of supposed trench fever upon the same medium remained sterile.

V. Animal Inoculations.

Rabbits, guinea-pigs, and white rats have been inoculated with the blood of patients and with suspensions of the tissue. In none of these animals were there obvious signs of illness; temperature charts of guinea-pigs and rabbits were continued for four and a half weeks without showing a febrile reaction, and examination of the blood on numerous occasions has failed, thus far, to show the presence of the parasite. Further experiments on animals are being undertaken.

VI. The Possible Occurrence of the Organism in the Louse.

Upon the arrival of convoys at the hospital lice were collected from the clothing of the patients and placed in small tubes labelled with the diagnosis upon the admitting card. Smears were made by teasing out the tissues and the intestinal contents on a slide, and stained with Wright's stain. A certain number of lice have also been sectioned and stained. While it is too early to report definitely upon this phase of our work, it may be said that there are present in a number of the smears small ring-shaped bodies identical in appearance with those observed in our cultures and blood smears. We have also observed larger forms, surrounded by a capsule, and transitions between the small discs and these larger bodies. In sections we have found within the alimentary canal large encapsulated globular bodies resembling the sporulating (?) encysted forms observed in the cultures. We are not yet, however, ready to present in detail our finding, but regard this merely as a suggestive observation.

General Discussion.

It will be seen from the above that we have up to the present succeeded in finding a characteristic organism in blood smears, in cultures from the blood, in sections of periosteum and fascia, and in cultures from these tissues.

The morphology of the organism obtained varies somewhat under different conditions. It is most definite and

constant in the blood smears, whereas in the sections of the tissue and in the cultures smaller forms are met with the relation of which to the organisms present in the blood requires further study. So also the significance of the larger encapsulated forms seen in certain of our cultures. Since, however, we have repeatedly found, both in the cultures and in the sections of muscle, forms practically identical with those observed in the blood, we are of opinion that we are dealing with varying forms of the same organism.

As to the nature of the organism, we cannot yet commit ourselves definitely. That it is not bacterial seems probable, (1) because of its characteristic morphology and the changes which it undergoes in culture; (2) because of its peculiar staining reaction, which distinguishes it from ordinary bacteria; (3) because of its failure to grow on the usual bacterial media; (4) because of the absence of all inflammatory reaction about the organisms in the tissue.

While it is impossible to classify the organism finally until its life-cycle shall have been more completely studied, we would provisionally assign it to the genus *Piroplasma*.

We are much indebted to Miss May G. Robson and Mdlle. Scheu for their valuable assistance in the collection of histories and preparation of specimens.

A METHOD TO FACILITATE THE ISOLATION OF THE CHOLERA VIBRIO AND OTHER ORGANISMS.

By ALDO CASTELLANI, M.D., M.R.C.P.,

LIEUT.-COLONEL ROYAL ITALIAN MEDICAL SERVICE (NAVY); MEMBER OF PERMANENT COMMITTEE INTERALLIED SANITARY COMMISSION.

The method here described is based on the action of specific and non-specific agglutinins on the bacteria with which the cholera vibrio is most frequently mixed in the material (stools) to be examined.

To explain the general principle on which the method is based the following experiments may be made:

Action of Specific Agglutinins.

I.

Take two tubes of peptone water: inoculate Tube No. 1 with *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B.

Inoculate No. 2 tube with the same germs, but immediately before or after inoculation add:

- 3 to 5 drops agglutinating typhoid serum,
- 3 to 5 drops agglutinating paratyphoid A serum,
- 3 to 5 drops agglutinating paratyphoid B serum, and shake well.

Instead of the individual mono-serums, 3 to 5 drops of a high titre trivalent serum may be used derived from a rabbit inoculated several times with typhoid, paratyphoid A, paratyphoid B. Incubate both tubes at 37° C. for twelve hours and examine. No. 1 tube will show diffuse cloudiness; in No. 2 tube, on the other hand, there will be no diffuse turbidity, the growth taking place at the bottom; the medium will be quite clear, or will contain only a few flocculi, which will very quickly go to the bottom on centrifuging.

II.

To a tube of peptone water add

- 3 drops typhoid serum,
- 3 drops paratyphoid A serum,
- 3 drops paratyphoid B serum.

Or instead of the mono-serums 3 to 5 drops of high titre trivalent serum may be added, derived from a rabbit repeatedly inoculated with typhoid, paratyphoid A, and paratyphoid B.

Shake well; inoculate the tube with *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, and *Vibrio cholerae*.

Incubate at 37° C., and examine after twelve hours. The medium will show diffuse cloudiness, often more marked towards the surface (with at times a pellicle), due to the growth of *V. cholerae*, and also a certain amount of bottom growth, and occasionally some flocculi due to agglutinated typhoid, paratyphoid A and B bacilli. These three bacteria have been influenced by the specific serums, which have had no action on the cholera vibrio. In carrying out this experiment care of course should be taken to use typhoid and paratyphoid serums containing no coagglutinin for the cholera vibrio, or only in very small amount. Certain powerful typhoid and especially paratyphoid A serums may contain quite an appreciable amount of cholera coagglutinin, which is, however, in very small amount in comparison with the other coagglutinins, and may be removed by absorption.

III.

To a tube of peptone water add 3 to 10 drops of polyvalent *B. coli*, *B. pseudo-coli*, *B. coli tropicalis*, *B. neapolitanus* serum, or 3 to 5 drops of each of the respective mono-serums. Inoculate with *B. coli*, *B. pseudo-coli*, *B. coli tropicalis*, *B. neapolitanus*, and shake well. Incubate at 37° C., and examine after twelve hours; the medium will be clear. Repeat the experiment, inoculating the medium with the same bacteria plus *V. cholerae*, and examine after twelve hours' incubation at 37° C.; the medium will show diffuse cloudiness, often more marked towards the surface (and at times a pellicle), due to the growth of the cholera vibrio, which has not been influenced by the serums added. Care of course should be taken to use serums containing no cholera coagglutinin, or only in minute amount.

Action of Non-specific Agglutinins.

I.

Add to a peptone water tube 3 to 5 drops of a very powerful agglutinating paratyphoid B serum, rich in specific and non-specific agglutinins. Inoculate the tube with *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, *B. aertrycke*, *B. enteritidis* (Gaertner), and examine after twelve hours; there will be no homogeneous growth, and no diffuse turbidity. The growth is at the bottom, and at times under the form of flocculi in the medium, which will quickly go to the bottom on centrifuging.

If, instead of a very powerful agglutinating paratyphoid B serum, one of low titre is used, containing only a very small amount of coagglutinins, the medium will show a diffuse turbidity, due to the growth of the *B. typhosus*, *B. paratyphosus* A, *B. enteritidis*, while bottom growth and flocculi will be present, composed of agglutinated paratyphoid B bacilli, and also *aertrycke* bacillus, because generally any paratyphoid B serum contains nearly as much agglutinin for *B. aertrycke* as for *B. paratyphosus*. These two bacteria can be differentiated only by my absorption method, as demonstrated by Boycott, Bainbridge, O'Brien, and others.

II.

Add to a tube of peptone water 3 to 5 drops of a very powerful agglutinating paratyphoid B serum containing coagglutinins for the typhoid-paratyphoid group of micro-organisms.

Inoculate with *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, *B. aertrycke*, *V. cholerae*. Inoculate at 37° C., and examine after twelve hours. There will be diffuse turbidity, due to the growth of the *V. cholerae*, and flocculi and bottom growth due to the typhoid, paratyphoid, and *aertrycke* germs; the flocculi may easily be got rid of by a short centrifugation which will have no effect whatever on the non-agglutinated cholera vibrios. After a few hours longer there may be a distinct pellicle composed of vibrios. Of course, in carrying out this experiment, care should be taken to use a paratyphoid B serum which contains no coagglutinin for *V. cholerae*, or only in very small amount.

From the above experiments, and similar ones, a general method can be devised to facilitate the isolation of the cholera vibrio, the typhoid bacillus, and other germs. The method consists simply in adding to the medium in which the material is going to be sown, serums influencing—that is, agglutinating, and delaying the growth of—the germs we do not intend to isolate, while they do not hinder appreciably the growth of the particular germ, or group of germs, we want to grow.

Cholera.

For the isolation of the cholera and paracholera vibrios from stools the following technique may be followed:

Inoculate peptone water tubes with the faecal matter in the usual way, but before or immediately after making the inoculation add to each tube:

- 3 to 5 drops polyvalent lactose fermenters faecal bacteria serum (*B. coli*, *B. pseudo-coli*, *B. coli tropicalis*, etc.), or the respective mono-serums may be used.
- 3 to 5 drops polyvalent non-lactose fermenter faecal bacteria serum (*B. proteus* group, etc.).
- 3 to 5 drops paratyphoid B serum.

The addition of the last named serum is made with the object of agglutinating and delaying the growth of the bacilli of the paratyphoid B and *aertrycke* type, which, in the tropics at least, are not very rarely found in the intestinal fluid. Care should be taken, of course, to use serums containing no coagglutinin for the cholera vibrio, or only in very small amount. Or serums can be used from which the cholera coagglutinin—which is always in very much smaller amount than the other coagglutinins—has been removed by absorption.

The tubes are placed in the incubator, and the further steps in the investigation are carried out in exactly the same manner as with the ordinary methods.

1. From the very surface of the medium a loopful of liquid is taken, examined microscopically, and the agglu-

tionation reaction with cholera serum carried out straight-way.

2. A small loopful from the very surface is smeared in the usual way on gelatine plates, bile salt neutral red agar plates, etc., and any suspicious colonies which will grow are further investigated.

The method may be applied to the isolation of the typhoid group of bacilli.

Typhoid.

To facilitate the isolation of bacilli of the typhoid-paratyphoid group the following technique may be used:

1. Inoculate with the faecal matter to be investigated several tubes of taurocholate of soda peptone water, or Browning, Gilmore, and Mackie's telluric acid peptone water might be used.

2. Immediately after, or better immediately before, the inoculation, add 5 drops polyvalent lactose fermenter intestinal bacteria serum, 5 drops polyvalent non-lactose fermenter faecal bacteria serum (*B. proteus* group, etc.), taking care to use serums containing only a very small amount of typhoid coagglutinin; or serums can be used from which the typhoid coagglutinin has been removed by absorption.

3. Incubate for twelve or twenty-four hours, then make plates on MacConkey, Conradi-Drigalsky, or similar media, from the most superficial portion of the liquid medium, and investigate further any suspicious colonies which may develop, testing them with typhoid, paratyphoid A, and paratyphoid B serums, etc. When there are many flocculi of agglutinated bacilli also in the upper portion of the tube, these may be got rid of by a short centrifugation. A short centrifugation with an ordinary electric centrifuge will cause the agglutinated bacilli to fall to the bottom, while it has practically no effect on the non-agglutinated germs in young cultures.

REMARKS.

In theory the method I have described is simple, and it should be possible by means of it to isolate in absolutely pure cultures the germs we want to grow to the exclusion of all those we do not want to isolate. In practice things are not so easy, and several difficulties are encountered: (1) The intestinal bacterial flora found in association with the cholera vibrio varies to a certain extent from country to country, from epidemic to epidemic, and even from individual to individual. Therefore, the serums used may have to be varied, and serums have to be prepared influencing a large number of intestinal bacteria. (2) The preparation of powerful agglutinating serums against certain intestinal germs is far from easy. (3) Occasionally certain intestinal micro-organisms are at first inagglutinable by their homologous serums, becoming agglutinable only after several transplantations on artificial media.

In practice, therefore, we seldom succeed in agglutinating and retarding the growth of all the species of germs we do not want to grow, but merely succeed in agglutinating and retarding the growth of a certain number of them. Even this result is, however, of practical importance, and greatly facilitates the isolation of the germs we want to grow.

ADAPTATION OF THOMAS AND JONES SPLINTS TO OBTAIN FIXATION OF THE ARM IN AN ABDUCTED POSITION WHILE THE PATIENT IS AMBULATORY.

BY

ROBERT B. OSGOOD, MAJOR, M.R.C., U.S. ARMY,
U.S. BASE HOSPITAL No. 5, WITH BRITISH EXPEDITIONARY FORCE.

THE war has demonstrated quite clearly that the ring and wire splints of Hugh Owen Thomas and those which Sir Robert Jones has devised are wellnigh universally adaptable. As surgeons become familiar with their use, and appreciate the soundness of their simple mechanical principles, they are becoming more and more the method of choice, and the results obtained are becoming more perfect.

The principle of extension by traction and counter pressure makes of these splints a unit apparatus which provides easy and comfortable transportation, and allows the detailed treatment in the base and home hospital to be continued with complete satisfaction without change of

the apparatus, which may be and now usually is applied at the casualty clearing station or even at the dressing station. Their comparative cheapness of manufacture, their small bulk, and easy packing, are other advantages possessed to the same degree by no other splints with which we are familiar.

We question, indeed, the wisdom of devising other forms of splints at the present time, since the benefits of unit constitution and universal use are so obvious that it seems

rather that all surgeons should train themselves in their use; nor is that training difficult.

Many orthopaedic surgeons have been accustomed to use plaster-of-Paris, and feel that equally good results may be obtained with these dressings in combination with metal or plaster bridges. It is clearly our duty at the base hospital to abandon these bulky casts, which are time-consuming in application, and demand the acquirement of a certain specialized technique. It is our opinion, after a

DESCRIPTION OF FIGURES.

[The diagrams are to scale about one-eighth natural size.—ED. B.M.J.]

FIG. 1.—Thomas knee and leg splint.

FIG. 2.—Thomas arm splint.

FIG. 3.—Jones humerus extension splint.

FIG. 4.—Jones "cock-up" or "crab" wrist splint.

FIG. 5.—Adaptation of Jones humerus splint (Fig. 3) to retain abduction and some degree of immobilization of the shoulder and upper arm. Splint turned upside down. Axillary rutch fits over humeral crest. Wire designed to extend above shoulder should be padded and obtains its bearing below crest, between the anterior superior spine and the great trochanter. One padded perineal strap and another padded crest strap hold splint fast to pelvis.

FIGS. 6 and 6A.—Adaptation of Jones humerus splint (Fig. 3) and Thomas arm splint (Fig. 2) used in combination. Extension portion of humeral splint bent out to fit over bars of arm splint and retained as they cross by adhesive plaster or metal tape. Purpose: To retain arm in abduction with elbow flexed and arm outwardly rotated to any degree, depending upon the bend of the forearm portion of the Jones humeral splint. Patient ambulatory. Extension on humerus in direction of shaft obtained by adhesive plaster or (better) glued strips. More perfect immobilization of humerus is obtained than in Fig. 5.

FIG. 7.—Same combination as in Fig. 6, but well arm passed through ring of Thomas arm splint, whose bars are bent out somewhat to fit over front and back of chest. Counter extension obtained by soft swathe fastened to ring and extending around thorax of injured side. This adaptation leaves axilla and shoulder girdle of injured side free from apparatus.

FIGS. 8 and 8A.—Combination of two Thomas arm splints (Fig. 2). Purpose: To retain arm in abduction, immobilize the humerus, and provide for hypertension of wrist while patient is ambulatory. One of the Thomas arm splints is applied in the usual way with extension. The other Thomas arm splint has its ring bent (with two monkey wrenches) downward towards the uprights in order to make it fit more perfectly over the pelvis. The uprights of this splint are bent upward to any desired degree, and the splint acts as a bracket. Where the two splints cross (the pelvic over the arm splint) the arm splint is bent with a slight inward angle, and the pelvic splint is bent with a slight outward angle. Splints are fastened together where they cross by adhesive plaster or metal tape. The hypertension of the wrist is obtained by suspending hand to the projection of the pelvic splint above the arm splint. Perineal and crest straps as in Figs. 5, 6, and 7.

FIGS. 9 and 9A.—Adaptation suggested by Captain E. C. Cutler, M.R.C., U.S.A. Combination of two Thomas arm splints (Fig. 2). Purpose: To retain arm in abduction with extension and leave injured shoulder and axilla free from apparatus, while patient is ambulatory. The arm splint is bent downwards an inch or two from its end, while the pelvic splint is bent at the ring, as in Fig. 8, and fastened to pelvis by the same straps. At the point where the pelvic splint meets the arm splint it is bent in a horizontal direction, running parallel to the arm splint and fastened to it by adhesive plaster or metal tape. Extension straps run to end of pelvic splint and counter extension transmitted to pelvis and thoracic bands running from ring on well side to about thorax on injured side.

FIG. 10.—Adaptation of Thomas knee and leg splint (Fig. 1) for shoulder and humerus. Purpose: For quick application in injuries of shoulder and upper arm. Ring of leg splint passed over well arm. Bars bent out to fit front and back of thorax. Ring retained in position by soft swathes passed through it and about thorax of injured side. Shoulder straps to hold bars in place. Leaves shoulder free on injured side. Extension in usual way to end of splint, and counter extension by means of thoracic swathe. The patient may be ambulatory to some extent, but on account of its weight the splint is more useful for bed treatment. Patient, however, may sit up easily for dressings.

FIGS. 11 and 11A.—Combination of Thomas arm splint (Fig. 2) and Jones "cock-up" crab splint (Fig. 4). Splint may be described as a "yoke" splint. Purpose: To obtain fixation of shoulder girdle and humerus, leaving back of thorax free, and in case of pelvic or upper thigh wounds avoiding necessity of a pelvic support while the patient is ambulatory. The weight of the arm is borne by the roof of the neck like a water-carrier's yoke. The forearm is supported with the elbow flexed on a Jones "cock up" crab splint (Fig. 4), the iron bar bent flat and then twisted about an angular bend near the end of the anterior thoracic bar of the Thomas arm. The single rivet in the Jones "cock-up" crab splint hand bar allows the splint to extend forward at any angle from the arm splint, and thus any degree of flexion of the elbow maintained. Extension on the humerus in the usual way to the end of the Thomas arm splint against a counter pull on the thoracic swathes extending from the ring on the well shoulder about the thorax on the injured side.

FIG. 12.—Simple method of maintaining tight extension straps with Thomas leg or arm splints, devised by Lieutenant F. R. Ober, M.R.C., U.S.A. A four or five inch wire board nail is inserted between the extension bands above knot, and twisted like the tightening stick in a "buck saw" or a Spanish windlass. The head of the nail is caught under or over one of the bars of the Thomas splint. Any degree of steady traction may thus be obtained. [There is an error in the drawing: the number of twists above and below the nail should of course be the same.]

war experience in which we employed almost exclusively and with satisfaction plaster-of-Paris dressings, that, except in the occasional case, equally good, perhaps better, results may be obtained by the use of the Thomas and Jones splints.

The suggestions made in this note are in no way modifications of these splints, but only adaptations which may possibly be found to increase their usefulness.

In fractures of the head or neck of the humerus and in injuries to the bones or muscles of the shoulder girdle we have been impressed with the value of fixation with extension in the abducted position. In our experience there are a surprisingly large number of these injuries. Not only may better alignment and more speedy subsidence of the septic process be gained by the abduction, but the

comfort of the patient seems greater in this position. There can be no doubt that future function is favoured also. As Sir Robert Jones has pointed out, even a stiff shoulder with the arm in at least 60 degrees of abduction provides a surprisingly useful limb. As soon as the septic process begins to subside and the temperature is under control, ambulatory treatment increases the resistance of the patient, and greatly simplifies his care.

It is with these ends in view that these adaptations have been planned. Sufficient trial has been given in the wards and in transport to England to seem to prove their practicability. Many other adaptations may easily be made, indeed have been made. These figures with their legends are merely suggestive and demonstrative of certain forms we have found useful.

A SPLINT FOR THE TREATMENT OF GUNSHOT WOUNDS INVOLVING THE SHOULDER-JOINT.

By J. CAMPBELL, CAPTAIN R.A.M.C.(S.R.).

THE treatment in a base hospital in France of a large number of gunshot wounds involving the shoulder-joint has impressed on me in the first place the great necessity for securing adequate rest and fixation, combined with extension, and in the second place the absence of any useful method for attaining them. Many cases, that came under my care last year after being treated for some time, showed a considerable degree of toxæmia, and not infrequently had the elbow close-in to the side, a bad position for ankylosis owing to the subsequent limitation of movement in the limb. The method of treatment I formerly adopted was merely to bring the arm to the fully abducted position, and secure it there by means of weight extension over a pulley. The abducted limb was slung in place from a Balkan frame placed crossways of the bed, at the level of the shoulders. Care was taken that the patient was never

the uppermost malleable band, is also turned forwards in the same way. To the extremities of these rigid, forwardly curved bands are attached the side pieces of an ordinary Thomas arm splint, in a position of almost complete abduction with very slight forward flexion. The splint is applied in the following way: The patient is placed on his back on the padded frame with the affected shoulder region lying over the gap in the frame, and securely fixed by bending the malleable iron bands to the contour of his body (Fig. 3). He is prevented from slipping up or down on the frame by shoulder and perineal bands fastened as shown. The affected arm is supported by rigid bands of perforated zinc, and fixed extension is applied, *not to the forearm, but to the upper arm*. In this way the elbow can easily be passively moved and thereby prevented from becoming stiff—a most important consideration in treatment. By passing a bandage, impregnated with French chalk, from side to side between the body and the frame several times a day, any tendency to a sore back is easily overcome.

By the use of this splint I have found that the patient can be easily nursed and the dressings changed without pain or discomfort, and without the general reaction described above. Certainly such cases as I have treated on this frame settled down more rapidly and required less interference than had formerly been the case. Furthermore, patients can be transported in it with ease.

FIG. 2.—Frame, back view.

FIG. 3.—Frame applied.

moved. The dressings were changed only once in five to ten days after slightly raising the patient's shoulders and pushing the bed from underneath towards the sound side, till the patient was lying on the edge of the bed with the scapular region exposed behind. The dressings could then be done with but little movement; in spite of this, however, there nearly always followed a not inconsiderable rise in temperature and pulse rate, lasting several days.

Accordingly the idea suggested itself that a splint made after the principle of a Jones's abduction frame for the lower limb would prove useful for such cases, and after having used it in several instances I am quite convinced of its efficacy.

The splint consists of an iron frame, as shown (Figs. 1 and 2), covered by a thick, firm pad. The frame and pad are cut away in such a manner as to allow of free access to the greater portion of the scapular region. Three pairs of malleable iron bands, running transversely, embrace the body (a) just above the trochanters, (b) at the level of the lower ribs, and (c) at or just above the level of the nipples. The upper and lower bands are joined together in their respective pairs by straps and buckles. On the side for which the splint is intended the uppermost malleable iron band is replaced by a rounded rod of stouter metal carefully padded—this acts as the point of counter extension. The band of the frame on this same side also is curved round above the shoulder and then turned forwards, and a stout bar, running transversely at the level of

After the period of acute sepsis subsided the cases were put up in plaster with the limb still in the abducted position, but with the elbow flexed, and windows were cut out to allow of access to the wounds. The cases were then sent to England as walking cases.

My thanks are due to Surgeon-General Sir George Makins, K.C.M.G., for the help he kindly gave me in having the splints made at the Base Dépôt Medical Stores, Boulogne.

THE Paris house of Masson announces that it has made arrangements to publish in two annual volumes papers founded on the work done at the Ambulance de l'Océan, La Panne, Belgium. The publication will be directed by Dr. Depage, with the assistance of Drs. A. P. Dustin and G. Debaisieux.

SCHWARZE (*Deut. med. Woch.*, August 2nd, 1917), in some comments on methods of treatment of bacillary dysentery in the field, is rather pessimistic as to the so-called specific treatments, such as antiserum, bismuth, etc. He has had the best results with daily injections of adrenalin up to six doses, combined with two or three injections of atropine. The colic and tenesmus were greatly relieved, and the styptic action of adrenalin was of value in severe and debilitated cases.

PNEUMOCOCCAL MENINGITIS.

BY

C. WORSTER-DROUGHT, M.B.CANTAB.,

TEMPORARY CAPTAIN R.A.M.C.,

OFFICER-IN-CHARGE CEREBRO-SPINAL FEVER WARD, ETC., ROYAL
HERBERT HOSPITAL,

AND

ALEX. MILLS KENNEDY, M.D.GLAS.,

TEMPORARY CAPTAIN R.A.M.C.,

BACTERIOLOGIST, ROYAL HERBERT HOSPITAL.

The following observations are based upon a study of nine cases of pneumococcal meningitis which have come under our direct care, the ages of the patients varying between the wide limits of three months and forty-one years. In five cases the disease was the so-called primary form—that is, no lesion conceivably due to active pneumococcal infection was discovered elsewhere. This diagnosis, in three cases, was confirmed by *post-mortem* examination; in the remaining two an autopsy was not obtainable, but, clinically, no other lesion could be detected. In four cases meningitis occurred as a secondary infection.

PRIMARY MENINGITIS.

Of the five cases, two were infants, aged three and four months respectively, one was a boy of 11, and two were adults aged 22 and 41. The adults had had catarrhal "colds" for three or four days, followed by severe headache, prior to the appearance of meningeal symptoms, while the younger infant had had sudden convulsions. Following the appearance of headache, vomiting occurred in four of the five cases, and delirium rapidly supervened in the two adults.

SECONDARY MENINGITIS.

Of the four cases in which meningitis occurred as a secondary infection to a focus elsewhere, in two the primary lesion was a lobar pneumonia, in one middle-ear disease, and, in the last, an empyema of the sphenoidal sinus. The number of cases of pneumonia in which a secondary meningitis occurs is probably less than 2 per cent.

Lobar Pneumonia.—The first case, that of a child aged 14 months, was admitted to hospital with a temperature of 103° F., pulse 140, and respirations 80. The only physical sign was distinctly impaired resonance over the upper lobe of the left lung, with somewhat diminished breath sounds; on the following day, however, bronchial breathing was present over this area, both in front and behind, and also numerous râles over the rest of the left lung. Neck rigidity was also present, the head showing a tendency to retraction, and the fontanelle increased internal tension. Lumbar puncture yielded a turbid fluid, showing numerous polymorphonuclear cells, with Gram-positive diplococci; on culture a growth of pneumococci was obtained.

The second case, a girl aged 5 years, was first seen with an ordinary lobar pneumonia affecting the lower lobe of the right lung. On the fourth day of illness extreme restlessness and irritability were noticed; neck rigidity and Kernig's sign were elicited, and lumbar puncture showed a turbid fluid containing pneumococci.

Middle-ear Disease.—The patient, a man aged 23, had had an ear discharge eight months previously, which persisted for a few weeks and then ceased. Five days before admission to hospital he complained of severe headache, and the discharge recurred next day. Two days later he vomited and became delirious the same evening.

Empyema of Sphenoidal Sinus.—In this patient, a man aged 26, headache had been present for a few days when one morning it became increasingly severe and he vomited. During the evening he was found to be quite delirious and sent to hospital. He had made no complaint of any symptoms referable to a pathological nasal or post-nasal condition, and the empyema of the sphenoidal sinus was discovered only upon *post-mortem* examination.

COURSE.

From the day of onset the course of the disease varied from three to fifteen days' duration in different cases. With two adults, aged 22 and 41, both cases of the primary form confirmed by *post-mortem* examination, the course of meningitis was extremely acute, lasting only three days; the temperatures were never below 101°, and often reached 104°. Five other cases were also acute; the one in which, *post-mortem*, the sphenoidal sinus was found filled with pus died four days after the commencement of headache. Both the children in whom meningitis occurred secondarily to

lobar pneumonia lived only two days after the appearance of meningeal symptoms. In none of the above cases did any lasting improvement follow the evacuation of cerebro-spinal fluid from the intrathecal space. A man aged 23, in whom meningitis occurred secondarily to otitis media, ran a course of nine days' duration, being continually delirious in spite of the daily withdrawal of 55 to 100 c.cm. of cerebro-spinal fluid, before sinking into coma. An infant of three months also continued for eight days acutely ill and with occasional convulsions. The courses of two other cases, both primary forms, were somewhat subacute; one was an infant, aged 4 months, who lived for twelve days with retracted head, arched spine, and occasional vomiting. Towards the end convulsions were frequent. The second subacute case is deserving of special mention.

The patient, a boy aged 11 years, complained of a headache and appeared generally unwell; three days later he vomited and seemed somewhat drowsy. For four days following this his condition remained about the same, the temperature remitting between 101° and 104°. When seen on the fifth day his mental condition was quite normal, neck rigidity moderate, and Kernig's sign positive. The heart, lungs, ears, and nose showed no abnormality. Lumbar puncture was then instituted, the fluid obtained being slightly opalescent and under moderate pressure; direct examination of films showed the presence of numerous polymorphonuclear cells but no organisms. On culture, however, a growth of pneumococci was obtained. Lumbar puncture was continued until the day before death, which occurred on the fifth day of illness; the withdrawal of 30 to 50 c.cm. of cerebro-spinal fluid was invariably followed by a fall in temperature, usually to normal or 99°. Throughout, the patient complained of headache of varying intensity. His condition continued with little or no alteration, either in the clinical signs or in the microscopical characters of the cerebro-spinal fluid, until the eleventh day. Muscular rigidity was then more marked, and during the evening he became delirious and incontinent for the first time. Lumbar puncture next day revealed a purulent fluid, which on microscopical examination showed numerous Gram-positive lanceolate diplococci; this was the first occasion on which organisms had been seen, in spite of prolonged search, on direct examination. Delirium and restlessness increased, flocculation and carphology appeared, and two days later the patient died.

SYMPTOMS AND SIGNS.

Temperature.—In the seven acute cases the temperature generally remained at a high level, varying between 101° and 104°, and seldom indeed falling below 100°. Lumbar puncture was without effect on the temperature in five of these cases; in one infant, a primary form, it was occasionally followed by a fall of about two degrees (103° to 101°), and in a second patient, with meningitis secondary to otitis media, the initial lumbar puncture produced a fall from 104° to 100°. Subsequent punctures had little or no effect on the pyrexia, although large amounts (85 to 100 c.cm.) of purulent fluid were obtained daily.

Of the two subacute cases, one has already been dealt with; the other, an infant of four months, admitted with a temperature of 102°, showed a fall to normal following the first lumbar puncture. After two days it gradually rose, with a few intermissions, to reach 103° on the ninth day, thereafter never falling below 100° and frequently reaching 105°. In all cases some rise of temperature occurred as death approached.

Pulse.—The pulse-rate was more frequent than is usual in either meningococcal or tuberculous meningitis. In one case only was it below 100 per minute on admission to hospital or when meningitis was discovered; in this case the pulse was 88, but after the third day it gradually increased to 140 towards the end of the course. After the first few days the subacute case, aged 11, running a course of fifteen days, showed a pulse-rate varying between 84 and 96, with an increase to 100 to 120 during the last three days. In all other cases it varied between the limits of 120 and 160. Excepting in very acute cases, the pulse-rate showed a greater tendency to vary directly with the temperature than is usually seen in meningococcal meningitis.

Respiration.—With the exception of the two cases with lobar pneumonia, the respiratory rate was at first comparatively slow, being 24 to 30 per minute in adults and 30 to 40 in children; the respirations increased in frequency towards the end of the course. In adults, both Cheyne-Stokes respiration and Biot's respiration were observed.

Vomiting, etc.—Apart from that occurring at the onset, vomiting was present in one case only, an infant aged 4 months. Profuse diarrhoea occurred at the onset in

another infant, and, early in a course of nine days, in one adult.

Mental Condition.—Delirium, varying from incoherence to noisy restlessness, was the general rule in adults; in the cases continuing for only three days it was rapidly succeeded by coma. Screaming occasionally occurred in one infant, while, in a subacute case, the mental condition remained normal until the eleventh day, when delirium appeared, the patient dying on the fifteenth day. All cases died comatose.

Sphincters.—Excluding infants from consideration, retention of urine was present in two cases on admission, followed later by incontinence. The subacute case showed no change in the sphincter condition until the eleventh day, when, with the onset of delirium, incontinence occurred. The remaining patients were incontinent throughout.

Cervical Muscles.—Pronounced retraction was present in the three infants, in the girl aged 6 years, and in one adult, a primary form, aged 22. In all other cases there was rigidity of the neck muscles throughout the course, including the subacute case; no retraction, however, appeared in these cases.

Kernig's Sign.—In infants of under 2 years of age, Kernig's sign is of no definite value in the diagnosis of meningitis; some authors state that it is a normal phenomenon at such an age, but this is incorrect. As a matter of interest, in one infant aged 13 months the sign was negative throughout the course of six days; in a second, aged 4 months, it was absent until the fourth day of illness, when it developed on the left side only, thus persisting until death on the twelfth day. In the last infant, aged 3 months, Kernig's sign was present on both sides throughout a course of eight days. In all other cases it was well marked.

Spine.—Spinal rigidity was observed in all cases. The infant aged 4 months died on the twelfth day in extreme opisthotonos, which had gradually developed during the previous days. Both the other infants also showed some degree of opisthotonos.

Deep Reflexes.—In one patient only, aged 23, were the knee and ankle jerks absent throughout the course of meningitis; in all the infants they were at first slight, but disappeared during the last two or three days. In one adult they were distinctly exaggerated; with the super-vention of coma they disappeared. Definite ankle clonus was not observed in any case.

Superficial Reflexes.—Plantars: Extensor responses were elicited in two patients only, aged 22 and 23. Active withdrawal of the leg on plantar stimulation, so frequently observed in early cases of cerebro-spinal fever, was present in four cases. Abdominals and epigastrics: These reflexes were absent throughout in all cases excepting three. They were slight at first in two adults, but disappeared later. In a subacute case they remained present until the eleventh day, disappearing with the onset of delirium and incontinence.

The reflexes, both deep and superficial, as a general rule, are directly proportional to the consciousness of the patient, being present in mild delirium and absent in more profound delirium and coma. The superficial reflexes disappear at an earlier stage than the knee and ankle jerks and, consequently, their absence, in the presence of other signs, rather favours diagnosis of meningitis.

Cranial Nerves.—The pupils were usually slightly dilated and reacted sluggishly to light; they were widely dilated throughout the illness in one adult dying on the fourth day. Inequality in size of the pupils was present in two cases only, an infant of 4 months and a boy aged 11; in the latter it developed on the twelfth day. This case was the only one in which definite strabismus was observed; it also appeared on the twelfth day, with an increase in meningeal symptoms, and was apparently due to an involvement of the right sixth nerve. One case, a man aged 23, had left facial paralysis, but this was due to involvement of the facial nerve by the infection from the middle ear, from which his meningitis originated; *post mortem*, pus was found in the Fallopian aqueduct.

Motor Disturbances.—Convulsions occurred at the onset in two infants; both showed recurrences during courses of nine and twelve days respectively. Catching at imaginary objects and picking at the bedclothes (flocilation and carphology) were present in two other cases.

Urinary Changes.—Glycosuria occurred on the eighth day of illness in a patient, aged 22, whose meningitis was secondary to chronic otitis media; he died on the ninth day. The glucose amounted to 5.8 grams per litre and its presence was confirmed by the phenyl-hydrazine test. The occurrence of glycosuria during the course of meningitis has occasionally been noted; it is possible that it may be associated in some way with a disturbance of the floor of the fourth ventricle, such as pressure from within by distension of its cavity, or irritation of its ependymal lining. In the above case *post-mortem* examination showed the fourth ventricle to be somewhat distended with turbid fluid. Glycosuria also occurred in two cases of meningococcal meningitis coming under our care; in both, the appearance of glucose in the urine was coincident with symptoms of a degree of hydrocephalus. Both patients eventually recovered. Albuminuria was present in four adult cases.

The Cerebro-spinal Fluid.—A turbid fluid was obtained at the first lumbar puncture in the four cases of six years and under; the fluids were withdrawn on the first day of meningeal symptoms in the two cases secondary to pneumonia, and on the third and fourth day respectively in the two primary cases. Of the remaining five, the cerebro-spinal fluid was definitely purulent in four adults, even at the first withdrawal, on the second or third day following the onset of illness. The first specimen of fluid from the last patient, aged 11 (the subacute case), was not obtained until the fifth day of illness; it was at first only slightly opalescent, and did not become purulent until the eleventh day. In the majority of cases there was a considerable increase in tension. In all, excepting the subacute case, pneumococci were both seen on direct examination of stained films and obtained in culture from the first specimen of fluid withdrawn. In the exception no pneumococci were seen in films until the eleventh day, when for the first time the fluid was purulent; the organisms were obtained in culture, however, from that evacuated at the first withdrawal. Cytologically all fluids invariably showed numerous polymorphonuclear cells, and occasionally a few mononuclears. On testing with Fehling's solution, no glucose was ever detected in any of the cerebro-spinal fluids, with the single exception of that obtained from the subacute case, aged 11, on the first day of withdrawal (fifth day of illness). Following this, however, it disappeared next day, and remained absent.

MORBID ANATOMY, ETC.

Post-mortem examinations were made on seven of the nine cases; the two in which permission could not be obtained were apparently instances of the primary form of meningitis, in that no lesion was discoverable elsewhere, the chest, abdomen, ears, and accessory sinuses of the nose all appearing normal.

Primary Meningitis.

Of the three cases examined, two were infants aged three and four months respectively, and one was a man aged 41 years. In all cases the convulsions were flattened and well marked; purulent meningitis was present. In two cases greenish-yellow pus was more abundant over the convexity of the cerebrum, almost completely obscuring the cortex; there was less purulent exudate over the cerebellum, and very little in the pons and medullary regions.

In the third case, an infant, there were patches of purulent exudate over the convexity of the cerebrum, with abundant greenish-yellow pus at the base, over and around the cerebellum, pons and medulla, being more plentiful anteriorly than posteriorly.

There was no pus found in the middle ears, in the frontal or sphenoidal sinuses, or in the ethmoidal air cells; nothing abnormal could be seen in the nasal fossae.

Secondary Meningitis.

1. **Lobar Pneumonia.**—In both cases the meninges were very red and injected, and showed patchy gelatinous exudate over the cerebral cortex, with occasional pus along the course of the blood vessels. There was also considerable sero-purulent exudate over the pons and medulla, and, in one case, over the cerebellum also. In the infant aged thirteen months the upper lobe of the left lung was consolidated; there was also oedema of the lower lobe, with adhesions at the base. The other case showed consolidation of the right lower lobe.

2. **Chronic Otitis Media.**—A well marked purulent meningitis was present, limited chiefly to the basal region of the brain and extending over the pons, medulla, and cerebellum; pus could be traced extending along the sides of the blood vessels up the lateral aspects of the cerebrum. The right middle ear showed old-standing purulent otitis; pus also extended along the

petrous bone to its internal tip, involving the inner ear, and appearing to be conveyed along the auditory nerve to the meninges. There was a small collection of thick pus lying between the dura mater and inner half of the petrous bone; in the Fallopian aqueduct pus was also found. No sinus thrombosis was present. Microscopical examination of films from both the meningeal exudate and the pus in the middle ear showed pus cells with numerous pneumococci; examination of the discharge from the external auditory meatus, during life, had shown *Staphylococcus aureus* and a Gram-negative bacillus, but no pneumococci were seen or cultivated.

3. *Empyema of Sphenoidal Sinus*.—The autopsy showed well marked meningitis with massive fibrino-purulent exudation, limited almost wholly to the basal region of the brain; there were a few small patches of purulent exudate in the neighbourhood of the great longitudinal fissure. The sphenoidal sinus was found to be filled with pus and also the posterior ethmoidal cells; the nasal fossae and other bony sinuses appeared normal. Films of the pus, both from the sphenoidal sinus and meninges, showed pneumococci.

In all cases the purulent exudate extended down the spinal cord. With regard to organs other than those already mentioned, the heart, liver, and kidneys invariably showed cloudy swelling; the spleen was occasionally enlarged and the pulp somewhat soft.

DIAGNOSIS.

Meningitis having been diagnosed by the rigidity of the neck muscles, Kernig's sign, etc., its causative organism can only be determined by bacteriological examination of the cerebro-spinal fluid. Even in the presence of pneumonia meningitis is not necessarily pneumococcal, as, in occasional cases of cerebro-spinal fever, a bronchopneumonia may at first mask the meningeal symptoms. The majority of the cases described above were sent into hospital with a diagnosis of cerebro-spinal fever; it was only upon finding pneumococci in the cerebro-spinal fluid that their true nature was revealed. It is frequently possible to diagnose tuberculous meningitis clinically, but, at the present time, it is safer to regard any other examples of meningitis as meningococcal until proved otherwise.

PROGNOSIS.

The prognosis of pneumococcal meningitis is exceedingly grave, and it is doubtful if any severe cases ever recover. Hemenway¹ reported the case of a child, aged 2 years, suffering from pneumonia, who on the twelfth day developed head retraction and signs of meningitis. Lumbar puncture revealed a clear fluid under pressure, from which pneumococci were cultivated. The meningeal infection, however, must have been very mild, as the cerebro-spinal fluid was clear, showing no cellular reaction, and the case recovered. Four cases of recovery are mentioned by Broadbent,² three being children and one a soldier. The latter does not appear to have lost consciousness, although the cerebro-spinal fluid was cloudy, and yielded a growth of pneumococci; the course of meningitis was of about twenty days' duration. Netter Shand³ and Carnarvon Brown⁴ have also recorded instances of recovery; that of the latter observer was a severe case, but unfortunately, beyond the statement that pneumococci were found in the cerebro-spinal fluid, nothing is said of the bacteriological findings. Shand's case was apparently very mild, the patient, aged 28 years, showing no deviation from normal consciousness, and recovering after a few days.

TREATMENT.

The treatment of pneumococcal meningitis is at present most unsatisfactory. The nine cases recorded here serve to demonstrate the failure of repeated lumbar puncture. Each patient was punctured at least once daily, and in some cases every twelve hours, the subarachnoid space being drained on each occasion, until practically no more fluid would flow. As a result of the drainage the symptoms were occasionally alleviated for a time, but the ultimate result was not affected. Vaccines may be of value, but it is seldom that a case lasts sufficiently long for vaccine therapy to have an effect.

We have found hexamine of no value in the treatment of meningitis. Since the chief therapeutic properties of the drug appear to be due to its oxidation into formaldehyde, which takes place only in an acid medium, it probably has little or no action in meningitis. In the course of the chemical examination of numerous samples of cerebro-spinal fluid from cases of meningitis, we have found less than 2 per cent. giving a very faintly acid

reaction. The fluid is usually faintly alkaline, but occasionally neutral; the indicators used were litmus, phenolphthalein and methyl orange. Hexamine can be detected in the cerebro-spinal fluid within an hour of administration by the 'mouth', but the Burnam-Ramini test fails to demonstrate the presence of free formaldehyde.

Lamar,⁵ working with monkeys, showed that sodium oleate attacked and dissolved pneumococci, and, when combined with a specific antipneumococcal serum, had a decided therapeutic effect on pneumococcal meningitis, even when the organisms were multiplying in the blood stream. The action, however, is restricted to the particular type of pneumococcus from which has been produced the immune serum in the mixture of serum and sodium oleate. When the infecting pneumococcus was different in type from that represented by the immune serum, no therapeutic action resulted. When, therefore, a satisfactory polyvalent immune serum is forthcoming, the most promising method of treatment would seem to consist in the intrathecal injection of the antipneumococcal serum mixed with a solution of sodium oleate.

AN INQUEST ON A LEG.

BY

NORMAN PORRITT, M.R.C.S., L.R.C.P.LOND.,

CONSULTING SURGEON, HUDDERSFIELD ROYAL INFIRMARY.

On April 6th, 1917, J. J., a master miller, disappeared from home. No trace of him was discovered until September 1st, when a fisherman found the remains of a leg in the river. In the hope that the rest of the body might be found the coroner ordered the river to be searched. This proving fruitless, the coroner decided to hold an inquest on the leg, and asked me to examine it and give evidence at the inquiry. The following notes of my examination may prove of interest.

On September 7th, five months and one day after the man disappeared, and six days after the leg was found, I made the examination. On the foot was a boot, which was identified by the village shoemaker as one he had made for the missing man. Under the boot was a stocking foot of blue homespun, joined to the leg portion behind the heel, the greater part of the front of the stocking being torn and missing. The missing man's wife identified the stocking, and also a bandage beneath it found round the ankle. It was clear, therefore, that the leg was that of the missing man.

The remains consisted of all the bones of the lower limb of the right side, more or less denuded of flesh. The femur was bare, except around the knee, from which the remains of the soft tissues, gradually tapering off, reached a point 4 in. above the middle of the patella. The head of the thigh bone, though denuded of cartilage, was undamaged; the neck was thick, strong, and sprang obliquely from the shaft; and all the bony prominences and depressions were strongly marked. The bone was a compact whole, without trace of epiphyses. There was no antero-posterior bowing of the shaft. It was the bone of a man in the prime of life.

The patella was in position, but bare, and, though the fibula was covered and the structures of the calf were present, the anterior surfaces of the tibia were bare, except close to the knee and the ankle. The foot was attached to the limb only by the tendo Achillis. There was no trace of the ankle ligaments, and the articular surfaces of the joint denuded of cartilage were exposed. The foot was shrunken and black, but, protected by the boot, the skin had not disappeared. Over the heel the papillary ridges were visible to the naked eye. Across the sole along the roots of the toes was a ragged cavity filled with soft soapy material, into which the structures had been converted.

The soft tissues of the calf and around the knee were dense and shrunken. An attempt was made to find the popliteal artery, to form an estimate of the man's age from the condition of its walls. But although the thick trunk of a nerve was isolated, the artery could not be found among the dense mass of homogeneous structure into which the soft tissues had been changed. Though the surface of the soft tissues was uniformly black, their substance was changed into dense white structures, and patches of white material studded their exterior.

There was no sign of old or recent injury, but on the upper third of the outer side of the femur the round shaft had been worn flat. The flat, slightly excavated surface was exquisitely smooth, and could have been caused only by long-continued friction, such as would occur if the limb had been caught and nipped, and swayed about by the current of the river. With the foot in its natural position the limb measured from the top

of the great trochanter to the sole of the foot 33½ in. The femur was 17½, the tibia 13½, and the fibula 13½ in. long. Since the inquiry I have learnt that the stature of the man was about 6 ft. 6 in.

When asked by the coroner if the man from whom the leg came was dead I had no hesitation in answering in the affirmative. A leg disarticulated at the hip-joint must have been separated from the body either by some one with anatomical or surgical knowledge, or by the maceration caused by long exposure to the elements. The possibility of its removal by deliberate surgical operation can be dismissed, for surgeons do not remove limbs with hob-nail boots, stockings, and dirty bandages upon them, nor, after the operation, throw them into the river. If the limb had been criminally disarticulated the man was certainly dead. All the factors of the case suggest that the separation of the limb from the body was due to the force of the current of the river, which the macerated tissues were unable to withstand. The smooth flattened surface at the upper third of the femur suggests that the thigh may have been caught with the body hanging free; when, owing to the weight and leverage of the trunk, separation of the trunk from the limb, rather than tearing of the limb from the trunk, took place.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

EMETINE DIARRHOEA.

In a paper on the treatment of amoebic dysentery, published in the *BRITISH MEDICAL JOURNAL* of November 13th, 1915, I drew attention to the fact that emetine hydrochloride, given hypodermically, produced diarrhoea in many instances exactly in the same manner as ipecacuanha when used in large doses for the treatment of amoebic dysentery. Since that time such diarrhoea has been described by some as an evidence of emetine poisoning, an eventuality to be avoided. An annotation on diarrhoea due to emetine, published in the *JOURNAL* of October 6th, 1917, endorses this view, and quotes an observation—a somewhat late one—by Kilgore and Liu, published in the *Archives of Internal Medicine* (Chicago, 1917), calling attention to the importance of recognizing this condition. The same authors make the statement that the diarrhoeic stools due to emetine are almost indistinguishable to the eye from those of the amoebic dysentery for which the drug is given, and that when emetine diarrhoea occurs blood and mucus reappear.

In the old days the *rationale* of the ipecacuanha treatment was to press the remedy until a profuse diarrhoea was produced, the stools then becoming liquid and of a canary-yellow colour. After the cessation of the drug, solidity of the stools was quickly obtained, and to all intents and purposes many of the cases were cured clinically. Whether this was a real cure or not, it is not altogether easy to determine now, because in those days the cysts of the amoebae were unknown and prolonged microscopic examinations of the stools after treatment were not carried out. Some of the cases certainly did relapse clinically and others, in the light of our present knowledge, very likely became cyst carriers.

Since the oral administration of emetine, in the form of emetine bismuth iodide, has come into vogue, diarrhoea has become even more marked than when the drug was given by the needle. This, however, as I have just said, is exactly what one aimed at in giving ipecacuanha. In addition to the specific action of the drug, the bowel is thoroughly washed out, and this mechanical process is beneficial and not detrimental. (Compare the saline treatment of bacillary dysentery.) A few days after the termination of the course (twelve consecutive nightly doses of 3 grains of emetine bismuth iodide) the stools begin to become solid, and in a few days more, if cure has taken place, are formed and of a normal consistence. The liquid stools produced by the emetine, apart from the absence of amoebae and cysts in them, are, as a matter of fact, easily distinguishable from the true dysenteric stools, and there is no excuse for any one pushing the remedy to such an extent as to cause dangerous symptoms and even death. One

might in a similar manner produce equally dangerous symptoms, namely, weakness and collapse, by giving repeated excessive doses of ordinary magnesium sulphate. If the diarrhoea is excessive it can easily be controlled by tincture of opium.

Reappearance of blood during treatment is very rare; when it does occur it is often due to piles, and this source of fallacy must be excluded before it can be said that the blood is coming from the bowel ulceration. As regards other toxic symptoms of emetine, though not denying that peripheral neuritis may occur if the drug is given in excessive doses, I have not yet seen it in a long series of cases treated by ordinary courses.

It must be remembered that all drugs are poisonous if given in too large quantities and over too prolonged periods of time, and emetine is no exception to the rule.

GEORGE C. LOW, M.D.,

Assistant Physician London School of Tropical Medicine,
Temporary Captain I.M.S.

TREATMENT OF PAINFUL SHINS, FOLLOWING TRENCH FEVER, BY ELECTRO-THERAPEUTICAL METHODS.

EVERY physician connected with troops on active service knows the condition which is now officially diagnosed as "trench fever." He also knows that were it not for the "painful shins" which almost invariably follow, the vast majority of "trench fever" cases would be fit for duty in a very short space of time, whereas, in fact, thanks to these "painful shins," the convalescent stage of the disease is very long and disappointingly prone to exacerbation.

During the early part of last winter I tried many things electrical for the relief of this condition, watching the cases in their wards as well as in the electro-therapeutical department, and by the end of November I had come to the conclusion that the best remedy was ionization combined with faradism. My method is as follows:

Using liquor iodi fort., a patch 1½ in. wide and 3 in. long is painted, well outside and parallel with the anterior border of the tibia, in the middle third of the leg, and ionized for ten minutes, at the maximum of 10 milliamperes, the negative electrode being placed over the painted area, a thick pad well soaked with 2 per cent. sodium salicylate in 3 per cent. sodium chloride being placed between.

On the second day, ionization, with sodium chloride only, is applied over the original site, the negative electrode being placed as before. Ionization is now stopped, and for the next three, and subsequent days, the muscles of the calf and leg are exercised for ten minutes daily with faradism.

As a rule the men tell one at their second or third visit that they have experienced immediate relief from pain; that they have slept better and feel much better in themselves, and where they do not do so the fact soon becomes obvious from their general appearance. I watched the earlier cases for some weeks, keeping them to see if there was any tendency to recurrence, and having satisfied myself that there was not, I proceeded to carry out the above course as a routine.

Statistics of 100 Consecutive Cases received from the Wards for Treatment.

Days under Treatment.	No. of Cases.	Days under Treatment.	No. of Cases.
1	0	10	12
2	3	11	1
3	6	12	2
4	14	13	1
5	11	14	3
6	14	16	1
7	10	20	1
8	15	21	1
9	2	22	1

Sent to England as unlikely to be well in three weeks 2

100

Average stay under treatment = 7.50 days.

It will be noted that 2 per cent. were sent to England after treatment had been begun, owing to slow recovery, and that 98 per cent. were sent to duty "A" or convalescent dépôt, the latter means of evacuation being only used where it was thought that the man's general condition required a little longer rest.

ALFRED J. H. ILES,
Captain R.A.M.C.(T.F.).

Reports of Societies.

THE EFFECT OF WAR BREAD ON HEALTH.

At the meeting of the Medical Society of London on October 8th, after the President, Sir STCLAIR THOMSON, M.D., had delivered an address on "The Founder and the Foundation of the Medical Society," a discussion on war bread and its effects on health was introduced by Dr. ROBERT HUTCHISON and Dr. E. I. SPRIGGS.

Dr. HUTCHISON said that the wheat berry consisted of three parts—the pericarp, germ, and endosperm. In making ordinary white (pre-war) flour only about 70 per cent. of the wheat berry was used, the germ and pericarp being entirely discarded and used mainly for fodder. In order to economize wheat it was now compulsory for millers to extract 80 per cent. of the wheat berry as flour, and some of the pericarp and germ was included. This Government regulation (G.R.) flour was the basis of war bread. Chemically such flour was richer in every constituent except starch than white flour, and in particular it was richer in vitamins and phosphorus. The question of its absorptibility as compared with white flour was still *sub judice*, but there was no reason to suppose that it was inferior in this respect to white flour provided it were finely ground. War bread, however, was not always made from G.R. flour only. The addition of other cereals (maize, barley, rice, oats) up to certain limits was allowed. The proportion of these added by different millers varied, and it had been found impossible to standardize the flour for the whole country. None of the added cereals, however, could be regarded as injurious, and all were valuable foods. Maize had come in for most popular criticism, but if properly ground there was no harm in it, and much of the hostility to it was due to prejudice. As regards the bread, it must be recognized that it was impossible to prepare from the present flour a bread which had the same *aesthetic* qualities as pre-war bread. The darker colour was of no importance, but the relatively lower proportion of gluten, especially when other cereals were added, caused the bread to be less porous. This drawback would become less as bakers acquired more experience with the flour. As regards its effect on health, it seemed certain that there was nothing *chemically* injurious in war bread; indeed, it was superior from a chemical point of view to white bread. Any ill effects could only be due to its *mechanical* properties (presence of grit, doughiness, etc.), and could only affect the digestive organs. The quality of the bread produced in different parts of the country, and even by different bakers, varied greatly in these respects, but from fairly wide inquiry there was no real evidence of any serious disturbance of digestion by the bread in the great majority of individuals. It must be remembered that patients were apt to find in the war bread a convenient explanation of any disturbance of health for which they could not otherwise account. In cases in which the bread seemed to disagree the effect of toasting and more thorough chewing should be tried. Dr. Hutchison added that he had not seen any patient in whose case he was convinced that the bread had affected the digestion unfavourably.

Dr. E. I. SPRIGGS said that he had not found it necessary to order white bread for the patients in Duff House, although there was always a good number of sufferers from digestive complaints. The war bread was, however, much better in some districts than in others. The complaints which followed the measures taken by the Government to make good the lack of wheat by the use of other kinds of corn were due to several reasons. The change in flavour was one. Another was the lack of skill and experience in making the bread with the new kinds of flour. Further, the mass of the people did not realize before the war that the cereals given to animals were good human foods; and did not know that by eating oats, barley, or maize themselves they could get from them many times the food value that was obtained by turning them first into animal food. He referred to the figures of Professor T. B. Wood,¹ who calculated that of nearly 17 million tons of various kinds of corn used in this country before the war only 5 million went for human food. This was less than the average production of home grown corn, which amounted to 6½ million tons. Dr.

Spriggs said that he had advocated the use in home-made bread of a mixture of barley flour or meal, oatmeal, rice or maize, in the proportion of one part of the meal to two parts of wheat flour or war flour. This was a higher proportion of other cereals than millers were using at present. Examples of these different kinds of bread were shown to the meeting, and tasted by the members. Breads were also shown in which the added cereal had been boiled before mixing with the flour, making a spongier loaf. In order to compare the digestibility of such bread with that made from wheat flour, experiments had been made by Mr. A. B. Weir, B.Sc., chemist at Duff House, and himself. The subject was a healthy young man, who took a mixed diet containing the same foods and in the same quantities every day, each article being weighed or measured accurately. The diet was as follows. *Breakfast*: Eggs, butter, bacon, marmalade, cocoa, milk. *Dinner*: Fillet of beef, potato, cabbage, rice pudding, tinned pears, butter, cream, black coffee. *Tea*: Butter, jelly, milk, cocoa. *Supper*: Clear soup, haddock, butter, cheese, coffee, milk. With this a loaf of bread weighing about a pound was eaten daily. The bread was composed of two-thirds of white flour, and a third of the meal or flour to be tested, and was made as described in Chapter IX of *Food and How to Save it*.² These breads were compared with bread made from white flour alone, also with a war bread containing 10 per cent. barley and 10 per cent. maize. All the breads were palatable, and were preferred by the subject to baker's bread with the exception of that made with maize, the proportion of which (33 per cent.) was too high for making nice bread. The war bread, which contained 10 per cent. of barley and 10 per cent. of maize, was thought to be one of the nicest. Each experiment lasted three days. The flours were analysed separately. The other foods were all minced, mixed together, and analysed. The excreta for each three days were collected and their composition determined. The results showed that although there were differences in the amount of protein, carbohydrate, and fat assimilated yet the variations were not of importance, the total amount of foodstuff assimilated when expressed in calories being almost the same in each experiment, namely, between 95 and 96 per cent. of the food value eaten. The experiments demonstrated that bread composed of mixed cereals in the proportions recommended was palatable, and, in this subject, proved as nutritious as white bread.

Professor W. H. THOMPSON, Adviser to the Ministry of Food, said that it was important to get protein food from a number of sources, because all proteins were not "adequate" for both growth and maintenance. Even maize had about one-third of its protein of the adequate type. He thought that much of the trouble was due to ignorance in milling and baking. In the early days millers had not the apparatus to grind maize to a sufficient degree of fineness. Observations were now being carried out which he hoped would enable that difficulty to be overcome. Samples of bread complained of had been sent to the Ministry of Food, but in no case could anything be found wrong except the colour.

Dr. E. KINGSCOTE said that in North Italy before the war a large part of the community lived altogether on maize, many having no other food, but they were well nourished and healthy. He thought that the admixture of two flours might be the cause of the difficulty. The grinding of the maize was not equal to the grinding of the wheat, and in baking, each required a different amount of time to arrive at perfect cooking.

THE PRESIDENT said that it was to be gathered from Lettsom's writings that the price of the quartern loaf in 1774 was 8d., but by 1800 he wrote that the quartern loaf was 1s. 6d., "a sum truly oppressive to the poor." With our present day quartern loaf at only 9d., after three years of world war, our population might take courage by seeing what our forefathers had to endure in the Napoleonic struggles. In 1774, Lettsom, amongst his numerous essays, printed one entitled *Hints Respecting a Substitute for Wheat Bread*. The substitute he warmly recommended was the fine flour of Indian corn, to be mixed with that of wheat in equal proportion. He added that, if rightly managed, the colour would be about the same as the standard wheaten bread,

¹ BRITISH MEDICAL JOURNAL, August 25th, 1917, p. 261.

² H.M. Stationery Office. 1917. Price 3d.

and about 2d. in the quartern loaf cheaper than the fine wheaten, when that might be at 8d. per quartern. After insisting on the great nutritive value and the agreeable sweet flavour of maize, he wrote that "Some, indeed, did not so easily reconcile themselves to it, which often arose from the mismanagement of grinding the corn or baking the bread." The bakers, he said, had not acquired the best method of preparing and mixing it with wheat flour; as to the grinding, he advised that the millstones should first be set so wide as only just to burst the thick farinaceous part of the grain, which should then be passed through a sieve, so as to separate "the part of the interior edge of the grain composed of a ligneous spongy substance, the middle of which was of a dark brown colour and of a bitter taste, which, if ground into the flour, gave it a disagreeable flavour." When this deleterious part had been separated on the sieve, the remainder was to be ground with the stones set so as to render it sufficiently fine. Lettsom also suggested the use of potatoes as a partial substitute for bread, and recommended the use of one-fourth of potatoes, and stated that if a little ground rice were added the bread was prevented from crumbling, a matter of consequence in a large family.

Reviews.

TREATMENT OF WAR WOUNDS.

DR. W. W. KEEN, Emeritus Professor of Surgery in Jefferson Medical College, Philadelphia, has compiled a report on the treatment of war wounds for the United States National Research Council, and especially for its Medical Committee, of which Dr. Victor C. Vaughan is chairman. It has been published recently in a volume¹ in Philadelphia and London, and is of great interest in that it presents in a brief form a review of the recent literature on military surgery, written by a surgeon whose experiences go back to the American Civil War of over fifty years ago.

After a short account of the respects in which the present war differs from previous wars, in which special attention is given to the effect of the large numbers engaged and to the severity of the infection of wounds, Dr. Keen devotes a special chapter to the Dakin-Carré treatment as described in the *JOURNAL* of February 24th, 1917, p. 264; it has been brought to perfection by Carré at Compiègne and by Depage at La Panne. Dr. Keen adds a note on the recent use of an oily solution of dichloramine-T as described in our columns by Dakin and Dunham on June 30th, 1917, p. 865; as an application for the treatment of gunshot wounds it is still under trial.

After a short chapter on the removal of foreign bodies Dr. Keen gives a chapter to tetanus, founded largely on the inquiries carried out by Surgeon-General Sir David Bruce. In the chapter on gas infection and gas gangrene Dr. Keen states that he saw no case of gas infection during the Civil War in America and only one case in civil life since then. With regard to gas gangrene, he accepts fully the doctrine that not only must all foreign bodies, including clothing, be removed from the wound, but all dead tissue also, the wounds being kept open and frequent antiseptic dressings used; he states his impression that Dakin's fluid, Taylor's quinine chlorhydrate, and possibly some other antiseptics, when properly used in connexion with these absolutely necessary means, will enable the surgeon to conquer the infection at the start if he sees the patient within the first twenty-four hours.

With regard to head injuries Dr. Keen quotes with approval Dr. Harvey Cushing's conclusion, as to which there is fairly universal agreement, "that almost all cranial wounds produced by projectiles, even though they appear trivial, require surgical investigation," the possible exceptions being tangential longitudinal sinus injuries, which, as Sargent and Holmes have pointed out in our columns, present unusual surgical risks, and "certain fractures of the base, due to perforating wounds, owing to their inaccessibility." Experience shows, Dr. Cushing says, that even apparently trivial scalp wounds may in the

end require extensive and elaborate operations after a thorough neurological study, including the use of the fluorescent screen and x-ray plates. Dr. Keen supports the views expressed by Bowlby and by Sargent, that removal of bullets, even when the wounds have healed and the risk of septic infection thereby largely diminished, must, even in skilled hands, be attended by an amount of damage which in most cases would have more serious neurological consequences than the presence of a septic bullet. This, Dr. Keen says, corresponds to what he has always stated to his students and always acted on to advantage—namely, "if the surgeon, by seeking to extract a missile retained in the brain, will do more harm than the missile, do not operate."

The chapter on abdominal wounds is founded largely on the papers by Lockwood and others, and Fraser and Drummond, published in our columns last March, and Dr. Keen adds his own testimony to the need of gentleness in handling. "No good surgeon," he says, "will handle bowel or other viscera roughly, or expose more than a foot or two at a time, nor dally with his operation. Speed, but never haste, is the rule. This is especially necessary when scores of cases may be urgently needing surgical relief." In an appendix Dr. Keen gives a number of extracts from personal letters received by him from surgeons working at the Western front in France.

We congratulate Dr. Keen on the production of a report so comprehensive. It will be of great use to surgeons newly undertaking war work not only for what it actually contains, but as a guide to the literature. It may not be out of place to add that medical officers of the United States army are invited to make use of the library of the British Medical Association, where a file of this *JOURNAL* and of most, if not all, the other periodicals quoted by Dr. Keen may be consulted.

THE CHEMISTRY OF LIVING MATTER.

THE cessation of respiration has always been regarded as the best evidence of death. Without some interchange of oxygen and carbonic acid through some of the body tissues life cannot be maintained. In a recent book entitled *A Chemical Sign of Life*,² published by the University of Chicago, an account is given of a series of experiments undertaken by Dr. SHIRO TASHIRO to prove that such interchange is as essential to all forms of living matter, vegetable as well as animal, as it is to man. Directing his attention to the detection of carbon dioxide proceeding from living tissues under varying conditions, he devised an extremely delicate test whereby the presence of one ten-millionth of a gram could be demonstrated with certainty. The test consisted in the formation of a precipitate of barium carbonate, easily visible through a hand lens, when carbon dioxide is brought into contact with a film of half saturated barium hydroxide solution. The ingenious apparatus in which the test is applied is fully described and figured, and appropriately named a "biometer." Waller and others have long since demonstrated the occurrence of electrical changes in the course of all vital processes, and it has thus been proved that chemical changes also are no less constantly present in all living matter.

The concise monograph in which Dr. Shiro Tashiro's work is recorded is written in clear and definite language, the subject is arranged in admirable order, and the whole account is interesting, original, and highly instructive. The experiments ranged over a wide field, but special attention was paid to the chemical changes taking place in living nerves, both medullated and non-medullated. It is clearly shown that the chemical change in a stimulated nerve is greater than in a nerve at rest, and that such changes ceased or were greatly diminished when the nerve was anaesthetized. "Irritability is the universal sign of life, and by it living matter adjusts itself to its environments"; but whether such irritability is the cause or the consequence of the chemical changes remains to be proved.

Fully alive to the possibilities of fallacy, as from the effects of decomposition, etc., the author safeguarded his experiments and checked his results with great perseverance, and the case that he has presented is proportionately

¹ *The Treatment of War Wounds*. By W. W. Keen, M.D., LL.D., Emeritus Professor of Surgery, Jefferson Medical College, Philadelphia. Philadelphia and London: W. B. Saunders Co. 1917. (Post 8vo, pp. 169. 1.75 dollars net.)

² *A Chemical Sign of Life*. By Shiro Tashiro, Instructor in Physiological Chemistry in the University of Chicago. Chicago: University of Chicago Press. 1917. (Cr. 8vo, pp. 142. 1 dollar net.)

convincing. The evidence that has thus been accumulated by means of the "biometer" is full of suggestion, and, the author believes, has brought us "as near as we have yet got to Life itself."

PAINLESS CHILDBIRTH.

A NEW presentation of the twilight sleep question from the woman's point of view is given in a volume entitled *Painless Childbirth*.³ It contains personal narratives of which one is that of Marguerite Tracy's sister and another that of Mrs. Boyd. It includes a careful and reasonable history of the whole subject of obstetric anaesthesia, translations of the official reports of the Freiburg school, and a preliminary account of methods which had up to the time of its writing been suggested for simplification and for the extension of the advantages of painless childbirth. Leaving on one side the question of approving an appeal to women on a medical issue, the presentation of the subject from a lay standpoint could not well take a less objectionable form. No effort is made to minimize the limitations of the methods in vogue owing to the special care which they need for their success, and emotional influences are not unduly stressed. It is a useful book for the doctor to read if only that he may appreciate at the full strength of this sober statement the demand that women are likely to make on the obstetric practitioner of the future.

NOTES ON BOOKS.

UNPERTURBED by the war, which has now advanced firmly into the fourth year of its existence, and month by month involves an increasing number of the inhabitants of the world, the Carnegie Endowment for International Peace has published its Year Book for 1917.⁴ Here those interested may read all that has been done—or should one say attempted?—during the past year to secure the millennium for which the Endowment has been struggling since its foundation in the year 1910. Here, too, are recorded its hopes for the active part it is to take in the international organization that must closely follow on the conclusion of the war. For the past work of the Endowment one may, perhaps, turn the page and say, Peace be to its ashes! For the future, one may wish it a resurrection in happier days.

Dr. T. F. G. MAYER'S *Formulary*⁵ of drugs for use in the tropics consists of an alphabetical list of certain drugs and their preparations found useful in the surgical treatment of disease as met with in these parts. The author writes from Sierra Leone, and has succeeded in constructing a catalogue of formulas that should be of service to workers in hot climates who are able to get hold of the synthetic and other drugs, many of them now difficult to obtain, with which he deals.

³ *Painless Childbirth*. By Marguerite Tracy and Mary Boyd. With nineteen illustrations from photographs. London: William Heinemann, 1917. (Pp. xxxiii+316. 7s. 6d.)

⁴ *Year Book for 1917* of the Carnegie Endowment for International Peace. No. 6. Washington, D.C.

⁵ *Formulary of Certain Drugs used in the Surgical Treatment of Tropical Diseases*. Compiled by T. F. G. Mayer, M.R.C.S., L.R.C.P. (Senior Medical Officer, Sierra Leone). Freetown: Government Printing Office, 1917. (Demy 8vo, pp. xiii + 91.)

MEDICAL AND SURGICAL APPLIANCES.

A Hook Pin for Bandages.

RATHER more than two years ago (June 12th, 1915, p. 1008) we described and figured a hook pin for puttees and bandages devised by Dr. C. R. Rutland. It has now been modified by the inventor to adapt it specially for fastening bandages. He claims that it combines simplicity, rapidity, and security, and these claims seem to be justified. The inventor, who has received a special permit from the Ministry of Munitions for sufficient steel to make 150,000 pins, is willing to send trial samples to surgeons and nurses having wounded soldiers under their care on application to him at 1, Weymouth Street, London, W.1. The device seems to us well worthy of such a trial.

THE annual report of the Surgeon-General of Public Health Service of the United States for the fiscal year 1916 contains a summary of the many activities of this department, together with statistical and other tables. It contains a great deal of matter interesting to public health authorities and medical officers of health, and conclusive evidence of the effectiveness of the public health service in America.

NATIONAL SERVICE MINISTRY.

ORGANIZATION OF MEDICAL DEPARTMENT: MEDICAL ADVISORY BOARD.

THE first meeting of the Medical Advisory Board of the Ministry of National Service was held at the office of the Ministry, Hotel Windsor, Victoria Street, S.W., on October 4th.

The general plan for the organization of the medical side of the work of the Ministry of National Service is somewhat as follows: The Ministry has a central medical department, of which Dr. James Galloway, C.B., is Chief Commissioner. The Ministry and Chief Commissioner have the assistance of a Medical Advisory Board, consisting of Sir Donald MacAlister, President of the General Medical Council, Mr. Hodsdon, President Royal College of Surgeons of Edinburgh (Scottish Medical Emergency Committee), Dr. Verrall and Mr. E. B. Turner (Central Medical War Committee), Mr. Charles Ryall (Committee of Reference, Royal College of Physicians and Surgeons, England), Professor Arthur Keith, F.R.S., and Colonel Arnall Jones, A.M.S.(T.)

Great Britain has been divided into ten regions, each of which is controlled by a commissioner, who gives his whole time to the work. The following have already been appointed:—London: C. R. Tyrrell, C.B., M.R.C.S., L.S.A. Yorks, East Midland: T. Wardrop Griffith, M.D., F.R.C.P. West Midland: W. H. Bull, K.H.S., V.D., F.R.C.S. South-Western: Sir James Porter, K.C.B., K.C.M.G., M.A., M.D. South-Eastern: Sir Chas. H. Bedford, M.D., D.Sc. Scotland: Norman Walker, M.D., F.R.C.P.E. These commissioners will organize, supervise, and co-ordinate the work of the National Service Medical Boards and the local collection and classification of the information and statistics obtained by the boards as to the physical condition of the male population of military age.

Each region has been divided into areas, and for each area one or more—as a rule one—National Service Medical Board will be appointed with a President, giving his whole time, and a rota of practitioners, selected in the locality with the advice of the Local Medical War Committee, each member of which will undertake to attend in rotation so many sessions of the Committee at fixed intervals. The frequency of the sessions will, of course, depend upon the amount of work to be done. At first, until arrears are overtaken, several sessions a week, possibly daily sessions, will be necessary.

A man who is dissatisfied with the decision of the National Service Medical Board by which he has been examined has the right of asking the appeal tribunal for a review of his case, and if the tribunal considers that he has advanced grounds *prima facie* for inquiry, it will refer the matter to its medical assessors for a further report. These assessors will be appointed by the Local Government Board in England and Wales, and the Scottish Office in Scotland to the number of two or three score for the whole country. The appeal tribunals will be grouped so that one set of medical assessors may serve more than one tribunal.

The Commissioners of Regions and the Presidents of National Service Medical Boards, being whole-time officers, will be paid annual salaries. The members of the boards and the assessors, being part-time officers, will be paid by fees for each session.

At the preliminary meeting of the Medical Advisory Board, Sir Auckland Geddes, who took the chair, was accompanied by Sir Horace Monro, K.C.B., Permanent Secretary, and other representatives of the Local Government Board.

In an opening address, Sir AUCKLAND GEDDES said that the Ministry was concerned with the problem of the organization of the man-power of the country, and had been engaged in designing the machinery to steer into the proper channels men available either as volunteers in various capacities or compulsorily called up for military service. The machinery already set up included departments of trade and commerce, of labour, of recruiting for the Royal Navy, Army, and Air Service, a medical department, a department of registration of the male population of military age, a statistical department, and finance and secretarial departments. These central departments must work through a

very large peripheral machinery, and in this connexion the Ministry was asking help from trade unions, employers' federations, and from medical organizations. Advisory boards had been formed to keep the central office in touch with the several parts of the civil machinery. They would serve as a series of liaison bodies. The work of the medical department must underlie much of the work of all the others, and several difficult problems had to be solved by it. The first was the organization of the medical examination of recruits; the difficulty of this task was increased by the past history of the subject. From the old peace plan of the examination of voluntary recruits at dépôts there grew up after the outbreak of war a system of medical boards which at first had only to decide whether a man willing to serve was fit to serve. The introduction of compulsory military service made a great change, and the duties of the medical boards became often the converse of what they had been in the earlier stage. The fundamental nature of the change in conditions had not at first been fully recognized. Since the beginning of the year, and especially since the Review of Exceptions Act was put into force, the work to be done presented a totally new aspect. Large numbers of fit and willing men had been withdrawn, leaving behind the less fit and less willing, and every month there was a deterioration in both respects. The Ministry was faced with a widespread determination to avoid military service; the experience of the early part of this year showed that there were a number of persons engaged in fostering this unwillingness who would no doubt continue their activities and take every chance of discrediting any medical organization dealing with the examination of men compulsorily called up. In the past the medical boards had not been free from faults; certain medical practitioners had given certificates of unfitness on the scantiest evidence and without due regard to the national need; there was no doubt that personation on a large scale had taken place. Again, medical men in good standing had in some cases given certificates which necessarily weighed with the tribunals and from their general tone conveyed the impression that the man had been improperly examined by the medical board before which he had appeared. In addition, there had been difficulties due to the fact that in a few instances members of medical boards had permitted themselves to be influenced by unworthy motives to grade a man in a low category. On the charge of personation and on other charges it had been necessary to institute during the past fourteen months about 14,000 prosecutions on one ground and another, so that the Ministry and its Advisory Board had to face the fact that there was a large volume of shady practices to be defeated. What was now aimed at was not merely to ascertain whether an individual man was fit to be employed in the army either as a fighting man or in clerical or other sedentary work, but to gain a definite body of information on the physical composition of the man-power left in the country. This was a very big undertaking, nothing short of a medical survey of the male population of military age. It was, moreover, possible that before long the military age would have to be raised. At present no one knew what the reserves of the country were in man-power of any grade of physical fitness. Another duty falling upon the Medical Advisory Board would be to arrange for the supply of medical men to the medical services of the army and navy and of the air service, and also to look forward to the future of the medical profession, and study the effect of the shortage of students at the medical schools. Finally, the medical survey of the male population would afford an opportunity, which should not be neglected, of obtaining anthropological information. The Ministry intended to work with the help of existing organizations of the profession on the one hand, and with the navy, army, Air Board, Pensions Ministry, and other departments employing medical men on the other. The matters to which he asked the Medical Advisory Board to give immediate attention were, first, to lay down a code of standards of physical fitness for the guidance of the National Service Medical Boards to ensure uniformity, so that the returns might be comparable; secondly, to form the National Service Medical Boards; thirdly, to arrange machinery for appeals by men dissatisfied with the decisions of those boards; and fourthly, to consider the supply of medical students to medical schools, and whether it would be necessary to bring back

men now serving in the combatant ranks who had a certain number of medical examinations to their credit.

SIR AUCKLAND GEDDES then called upon Dr. JAMES GALLOWAY, the Chief Commissioner Medical Department of the Ministry of National Service, who said it was hoped in constituting the National Service Medical Boards to have the assistance of Local Medical War Committees. A board would generally consist of a president and four other medical members. He hoped that panels of medical men would be chosen from men in the various localities who had the confidence of their professional brethren. There might be, for instance, in an area a panel of eight or ten, so that no one member would have to give his whole time. In some areas it would be necessary to form new boards, and in so doing the department hoped to receive local recommendations through the Central Medical War Committee and Committee of Reference or the Scottish Medical Service Emergency Committee, as the case might be. The country would be divided into regions with a whole-time commissioner at the head of each, who would, in organizing the boards and selecting their members, consult with the local representative committees of the medical profession in the areas served by the boards. The presidents of boards would in nearly all cases be whole-time officers, who would be members of the staff of the National Service Ministry; they would be chosen by the central department and, speaking generally, would be men not connected with the particular locality. In the choice of presidents of National Service Medical Boards, the advice of the local commissioner would be obtained, and, as a rule, it would be desirable that the president should have some knowledge and experience of military service and organization.

In answer to questions, Sir AUCKLAND GEDDES said that undoubtedly some medical boards wanted overhauling with the help of the Local Medical War Committees and of the Central Medical War Committee. Nominally the medical boards appointed by the War Office would cease to exist when the work was transferred from the War Office to the National Service Ministry. With regard to the right of appeal to be given to men dissatisfied with the decisions of National Service Boards, it was proposed to set up groups of medical assessors, to be appointed and controlled by the Local Government Board in England and Wales, and by the Scottish office in Scotland.

SIR HORACE MONRO, K.C.B., Permanent Secretary to the Local Government Board, said that a man graded by a medical board could claim to have his case reviewed by the appeal tribunal, and if that tribunal thought that he had a *prima facie* case it would authorize him to go before the medical assessors. In the selection of these medical assessors and in the organization of their work the Local Government Board hoped for the assistance of the National Service Medical Advisory Board. There were about sixty appeal tribunals in England and Wales, but it would probably not be necessary to nominate so many assessors. He hoped that the medical assessors selected would be as a rule men of good standing of the general practitioner type; they would act together in local groups of three or four working together and would receive remuneration at a rate of so much per session, morning and afternoon. At the suggestion of Sir Auckland Geddes this matter was referred to a subcommittee consisting of representatives of the Local Government Board, the Scottish Office, Mr. E. B. Turner, Mr. Hodsdon of Edinburgh, and Mr. Ryall, member of the Council of the Royal College of Surgeons.

The question of drawing up a memorandum of directions as to standards of physical efficiency for the guidance of National Service Medical Boards was referred to another subcommittee, including representatives of the army and navy. With regard to the last matter—the supply of medical students to medical schools—Sir Auckland Geddes said that he believed the Royal Navy required five hundred surgeon probationers (students) within the next twelve months, while the army asked for newly qualified men. It was a fact that a fair number of students who had passed some medical examination were now serving in the army. These matters were referred to another subcommittee.

In conclusion, Sir AUCKLAND GEDDES expressed the hope that the subcommittees would get to work at once, and in particular that the committees charged with the duty of advising on the setting up of the National Service Medical Boards would report at a very early date.

British Medical Journal.

SATURDAY, OCTOBER 13TH, 1917.

MINISTRY OF NATIONAL SERVICE.

THE Minister of National Service has during the last ten days taken the public fully into his confidence, and it will have been gathered that it has been found necessary to establish a very large organization, both central and peripheral, for dealing with the many duties—some of them new—imposed on the Ministry.

Its first and main duty is to review the whole field of British man-power so as to be able at all times to give the War Cabinet information as to the meaning, in terms of man-power and consequential results, of all departmental proposals put forward. It will make the arrangements for the transfer from civil work not declared by the War Cabinet to be of primary importance, or if ordered by the War Cabinet, from the navy, army, or air service to urgent national work, of such numbers of men as may be declared by the War Cabinet to be necessary to reinforce the labour already engaged on that work. Subject to the approval of the War Cabinet, it will determine—in consultation with the departments concerned—the relative importance of the various forms of civil work and prepare lists of reserved occupations, with such age and other limitations as may be necessary to secure the maintenance of essential public services, and the preservation of a nucleus of civil occupations and industries.

In respect of the military forces it will be its duty to obtain for the army, navy, and air service, within numerical limits imposed by the War Cabinet, such men as can be withdrawn from civil life without detriment to the maintenance of essential public services and the due performance of the civil work necessary to maintain the forces at sea, in the field, and in the air, and any nucleus of civil occupations and industries declared by the War Cabinet to be necessary. In connexion with this last duty the Ministry must determine the physical fitness of men available, or possibly becoming available, for withdrawal from civil life. Its functions in this respect are limited by the action of the tribunals acting in conformity with regulations and instructions issued to them. The Ministry will also make arrangements for the provision, where necessary, of labour (male and female) in substitution for that withdrawn from civil life. For the better carrying out of these various duties it has been decided to establish in the Ministry eight departments—labour supply, trade exemptions, recruiting, registration, medical, statistics, finance, and secretariat. The first six will each have an advisory board, and will work largely through local agencies, chiefly those already in existence. For the office of the Chief Commissioner of the Medical Department, the work of which, as Sir Auckland Geddes said in the speech he delivered at the first meeting of the Medical Advisory Board, reported elsewhere in this issue, underlies nearly all the others, he has been fortunate enough to obtain the services of Dr. James Galloway, who has recently added to his long and varied experience of civil practice an acquaintance with military requirements and methods gained during a period of service as consulting physician to one of the armies in France. For the purposes of this medical administration Great

Britain has been divided into ten regions, one each for Scotland and Wales and eight for England. At the head of each will be a regional medical commissioner, who will give his whole time to the work and be paid by salary. He will be responsible for the administration of the new civilian National Service Medical Boards. The regions will be divided into recruiting areas, with a deputy medical commissioner for each, who will be president of the National Service Medical Board of the area. He will be a whole-time officer appointed by the Ministry, and, in fact, one of its staff. The Medical Advisory Board of the Ministry is representative of the chief professional organizations, and one of its first duties will be to prepare a list of medical practitioners of good standing and known competence prepared to act on the National Service Medical Boards in the various areas on a part-time basis. In forming these lists the Medical Advisory Board will consult the Local Medical War Committees and the central committee in England and Scotland; it is intended that in each area the number chosen shall be in excess of that required to attend any particular session of the board; that is to say, it is proposed to form a rota of local practitioners willing to give their services for a certain number of hours on certain days in the week, or perhaps less often after the first pressure of work has been got through. They will be remunerated by way of fee for each session attended.

The primary duty of the National Service Medical Boards will be to classify each man into one of four grades: in the first, men organically sound and in all respects physically fit for military service; in the second, men organically sound but with some defect either of special senses or in limbs, or some other system. To the third will be referred men falling between the second and fourth categories; they will be marked at the time of examination according to the work for which they are deemed to be fit, and will be called upon when needed for such work. To the fourth will be relegated men so unfit as not to be suited for military or national work of a strenuous kind. In the discharge of these duties the boards will be guided by a memorandum as to standards of physical efficiency which will be issued by the Ministry. A draft made by Dr. Hale White as editor-in-chief, with the assistance of experts in each speciality, has been referred to the Medical Advisory Committee for its approval.

A man who, after being examined and graded by a National Service Medical Board, considers that his physical condition has been modified, will be entitled to apply to the deputy medical commissioner for re-examination by the board. If after this re-examination he is still dissatisfied, or if re-examination be refused, or if even after original examination he considers he has a grievance, he will be entitled to appeal to the ordinary appeal tribunal. In such a case the matter will pass out of the hands of the Ministry of National Service. If the tribunal considers that the appellant has made out a *prima facie* case he will go before medical assessors, now being appointed in England and Wales by the Local Government Board, and in Scotland by the Scottish Office, and the decision of the assessors will be accepted by the Ministry of National Service. These assessors will be remunerated by fees.

THE CARE OF THE BLIND.

THE President of the Local Government Board took the occasion at a meeting at the London Mansion House on October 4th, in aid of the funds of the London Society for Teaching and Training the Blind,

to make a pronouncement on the whole position as to the blind in this country, their care, education, and employment. Mr. Hayes Fisher stated that he had been much impressed by the evidence given before the Departmental Committee, of which he is chairman, on the condition of the blind throughout the United Kingdom, of which we gave an account on August 18th. If its recommendations were carried out he believed that the number of blind in the country would be gradually but substantially diminished. He hoped to set up in the Local Government Board a small department with an advisory committee which would take control of the whole of the work for the blind in the country. To carry out such work a substantial capital sum and an annual grant would be asked for. Further, he stated that he was by no means content with the present position regarding the prevention and treatment of ophthalmia neonatorum, which alone was responsible for the causation of fully 10 per cent. of the total blindness. He hoped that shortly local authorities would stiffen their methods of inspection and nursing, and he was taking steps to secure more hospital accommodation for the treatment of the affected infants and their mothers.

This statement by the President of the Local Government Board marks a distinct step in advance in the recognition by the State of its responsibility for the prevention of blindness and for the care of the blind. Up till now the blind have been mainly cared for by voluntary effort, and noble work has been done by voluntary agencies, whose work will always be needed to give that touch of kindness and humanity which State provision can scarcely provide. But the exigencies of modern conditions, and the extension of legislation for the protection of industrial workers, such as the Employer's Liability Acts, have acted as a serious handicap to the blind. The risk of the employment of seriously disabled persons is now so great that the blind are less acceptable as workers than formerly. Such a position needs to be met by the provision of workshops for the blind—places where they can do their best work, protected from the disturbing effect of the keen competition of the sighted, and relieved from the necessity of themselves finding the market for their productions.

The society, for whose benefit the meeting at the Mansion House was held, works in the north and north-western districts of London and oversees the wellbeing of some 1,500 blind persons. It is now seeking to make better provision for the young persons who have left the elementary schools, and to give them a start in life, without which much of the good work done in the schools is lost. There is, indeed, great need of a better organization of the existing provision for the training of the blind. Voluntary effort is essentially local. The pity of the beneficent is drawn to the needs of their own blind, and schools have sprung up here and there for this purpose. The numbers of the blind are small, so that in one school there are blind of many types and grades of intelligence and capability. Under such conditions the best of the blind cannot rise, or rise with difficulty, above the general level of equipment provided for the average. What is wanted is a combination associating all these schools, so that there may be a specialization of work in the several schools. Under such conditions the best of the blind, those whose condition is due to more or less accidental causes and not to hereditary disease or defect, would secure the stimulus of the society of their compeers; whilst the less favoured ones would not be left in the backwater of a school, but be assured of that fostering care which their condition merited.

Mr. Hayes Fisher's comments on the unsatisfactory provision for the prevention and treatment of ophthalmia neonatorum, especially in London, are true in fact; but the deduction that London is to blame for this lack is not true. The defect is much more the result of the handicap presented by central department control. London ophthalmic surgeons have agitated for years, and have found a dead weight of officialdom in their path. Only so lately as June of this year a deputation from the Council of the Metropolitan Counties Branch of the British Medical Association waited upon the Metropolitan Asylums Board, the London County Council, and the President of the Local Government Board, to represent the urgency of a better provision for the treatment of the mothers and infants when this affection was manifest. The plea of the deputation met with sympathy truly, but there was always some lion in the path, or the thought that it was someone else's work.

Let us hope that the days of the blind beggar will soon be passed, and that the blind will take their place in the community with self-respect unimpaired. Not all the blind desire this; some remember the ease of the pitiable beggar's position, and prefer it to work, but this spirit is declining. The blind man with the dog, a placard, and a tin can will soon be a relic of the past. Possibly also the familiar figure of boyhood days—the old blind man sitting under a railway arch reading from a great book with mysterious raised letters—will be lost also. The work of these blind readers was not altogether a loss to the community. Not all the blind are fit for, or succeed at, handicrafts or clerical work; maybe there is a place for those whose chief skill is in reading. There are still villages in the depth of the country where news goes from mouth to mouth; where the source of knowledge is the market town rather than the newspaper, and where the word of the Food Controller does not run. Why should not some of these blind become authorized readers duly accredited to certain districts, and the means of communication between the country folk and the larger world around them? But they would no longer live on the precarious collection of the tin pot slung about their necks; the new readers would be the salaried officers of the Government.

THE PROPHYLAXIS OF SYPHILIS.

LAST January Sir Bryan Donkin, by a letter in the *Times*, to which we then called attention, raised the question whether the propaganda for the prevention of venereal diseases ought not to include a frank statement as to the therapeutic measures of prophylaxis which have been devised, having no doubt chiefly in mind the prophylaxis of syphilis by the method originated and tested by Metchnikoff and Roux. Down to that time the propaganda had been limited to an appeal on moral grounds, an appeal to reason pointing out the dire consequences of infection, and the offer of free and secret treatment of the diseases in their early stage. Sir Bryan Donkin's letter met, as he no doubt expected, with a mixed reception. No one nowadays probably would deny to an infected person the advantage of the best that medical treatment has to offer. At any rate, the official scheme for making such treatment easily and generally accessible has been put into force with general public approval; but there are those who dread what they believe would be the antimoral effect of publicly recommending prophylaxis before infection is declared. We may, perhaps, get a clearer idea of the contention of those who think with Sir Bryan Donkin by asking what would have happened if syphilis were not a disease usually disseminated by sexual irregularities, and had a method of

prophylaxis, including prevention of the development of the disease after exposure, been devised, and proved by crucial experiment to be highly efficacious. There can be no hesitation in affirming that the facts would have been made known first by individual medical practitioners and by public health officials in their reports to local authorities, and would eventually have attracted the attention even of the Local Government Board. The nature and results of the experiments of Metchnikoff and Roux were promptly and fully published by the medical journals in this country, and in due course found a place in textbooks. No one could be deterred from recommending the prophylactic by the fear of doing any physical injury, for the local application of calomel ointment to skin or mucous membrane is free from any risk; yet Sir Bryan Donkin asserts that "outside the medical profession at least there is little or no knowledge concerning the prophylaxis of venereal disease." This statement implies that the medical profession has this knowledge, and it must be qualified by the admission that medical knowledge as to the prevention of gonorrhoea is very incomplete, and that though the efficacy of the Metchnikoff prophylaxis of syphilis is high, it is not absolute. There are cases where a man is morally bound to expose himself to an infection, to diphtheria or typhus fever for instance, but there can never be any moral obligation to run the risk of contracting venereal disease through illicit sexual intercourse. Therefore, if a civilian medical practitioner is asked by a person who proposes to indulge his appetite in this way how he may do so without risk, the nature of the answer is a matter for the exercise of private judgement, but it seems to us that a refusal would be justified not only on social and moral grounds, but also on the scientific ground that the known facts do not justify any such positive assurance. The position is different if he is consulted after the inquirer has exposed himself to the risk of infection. He must give the best advice he can, guarding himself by the statement that it is the best means known but in such circumstances very far from infallible. Very seldom, however, is medical advice sought until the disease has declared itself. The dissemination of information about the prophylaxis of syphilis is a matter for the public health authorities, and, as Mr. Ernest Lane, who is quoted with approval by Sir Bryan Donkin, has said, it is within the competence of the Local Government Board to turn its attention to the prophylaxis of venereal disease, to subject all plans to thorough investigation, and to publish the results for the information of the public. In the navy and army the place of the civil public health administration is filled by the medical services. In the forces on active service the social conditions are so abnormal and the military effects of venereal disease so serious that the problem may have to be dealt with on lines which may not be applicable to civilian life.

ANATOMY AND STATECRAFT.

THREE and a half years ago, speaking at a banquet given in his honour, one who had recently given up the teaching of anatomy for a parliamentary career made a claim which the war has confirmed in a rather striking manner. Addressing the chairman, who is now Prime Minister, he said: "I do not shrink from saying that you will go far, Sir, in the ranks of medicine to find a wider-minded and more capable set of men than British anatomists, taking them altogether." At the present moment two of the most responsible posts in the Government are held by former teachers of anatomy. Sir Auckland Campbell Geddes, lately Director of Recruiting, and now Minister of National Service, began his career as assistant professor and demonstrator of anatomy at the University of Edinburgh. He then became professor of anatomy in the Royal College of Surgeons of Ireland, and at the outbreak of war was professor of anatomy in McGill University,

Montreal. Dr. Christopher Addison, lately Minister of Munitions, and now Minister of Reconstruction, was in succession professor of anatomy at University College, Sheffield, lecturer on anatomy at Charing Cross Hospital, and lecturer on anatomy at St. Bartholomew's Hospital. There is nothing very strange in a mind trained in the science of anatomy turning towards the larger business of statesmanship. A Victorian philosopher once said that "analysis has for its chief function to prepare the way for synthesis"; and history records many instances of the two mental processes being highly developed in the same person. Study of the organization of the human body, and the habit of precise thinking and speaking proper to a man of science, have been no handicap to Sir Auckland Geddes in the organization of man power. His knowledge of the construction of the human frame will likewise stand Dr. Addison in good stead in reconstructing the fabric of civilized life after the upheaval of war—a task more congenial to him, perhaps, than co-ordinating agencies of destruction. Neither statesman will find, in carrying out the work which lies before him, any cause to regret the "curious observations which he had lately made in an anatomy of an human body," to use the words written by another Addison 200 years ago.

THE CAUSE OF TYPHUS FEVER.

THE infecting agent in typhus fever has long been sought for and has long eluded capture. Its discovery has often been reported, however; bacilli, cocci, bacteria, and intracellular bodies have all been described since the year 1910 as the causal organism of the disease. The latest explorer in these regions of the unknown is Professor Kenzo Futaki, of Tokio, who indicates a spirochaete, named by him *S. exanthematophyi*, as the cause of typhus fever. An announcement of his claim was made in the JOURNAL of August 25th last, and the steps that led up to it are related in a new monthly periodical,¹ published in Tokio, in which a very competent editor attempts a running review of thought and achievement in the Eastern and Western worlds for the benefit, primarily, of Japanese readers. Professor Futaki has been engaged in the investigation of typhus fever since 1915, and since April of this year has found a spirochaete, which he believes to be characteristic, in sections taken from the kidneys of seven out of eight patients dying of the disease in Japan. The same organism was discovered in the urine of six out of seven other typhus patients. It was discovered also in the kidneys, urine, and suprarenal glands of a rhesus monkey injected with the blood of a human being suffering from typhus fever, but it was not found in six other monkeys presumed to be normal. The spirochaete is described as resembling the *S. pallida* in form; it is from 6 to 8 μ in length, with from 5 to 7 spirals; it is vigorously motile and ciliated at the ends. It can be stained by silver and by Giemsa's stain. Professor Futaki adds that the virus of typhus fever is filterable and that he has found it in lice. It will be remembered that Nicolle, working in Tunis in 1909 and 1910, showed that the clothes louse serves as carrier of the typhus virus, and that he found the louse able to pass on the disease only after the lapse of three or four days, and only for a period of four days. Nothing is said as to the artificial cultivation of Professor Futaki's *S. exanthematophyi*; he is proceeding with his investigations, and their extension and confirmation will be awaited with interest.

THE ATROPINE TEST FOR THE ENTERIC FEVERS.

AN antityphoid vaccine known as T.A.B. has been used very extensively for the protective inoculation of our troops serving abroad, a fact familiar to all of us. This triple vaccine protects against infection with typhoid, para-

¹ The New East (Shin Toyo), Tokio, August, 1917, vol. i, No. 3.

typhoid A, and paratyphoid B fevers, and in practice it has proved of the greatest value to our soldiers. But from the point of view of the clinician, treating cases of fever among our troops abroad, this prophylactic use of T.A.B. has one grave disadvantage. Under the ordinary conditions of service it prevents the employment of Widal's reaction for purposes of diagnosis in obscure cases of fever. In skilled hands and with adequate laboratory conveniences, as Major Dreyer has abundantly shown, the modified and quantitative Widal test can be made to differentiate between the effects of T.A.B. inoculation and those of a superadded typhoid or paratyphoid infection. But this differentiation hardly as yet comes within the scope of routine work, with the result that the diagnosis of mild typhoid or paratyphoid infections has become a matter of the utmost difficulty. Nearly a year ago Captain H. F. Marris published in the JOURNAL a preliminary report on the use of atropine as an aid to the diagnosis of typhoid and paratyphoid A and B infections (November 25th, 1916), and promised a fuller report, which has now been issued by the Medical Research Committee.¹ The use of the atropine test is simple: the patient lies horizontally, and is instructed to remain completely quiet throughout the test, which is not employed till at least one hour after the last meal. The pulse-rate is counted minute by minute until it is found to be steady—usually a matter of ten minutes. Atropine sulphate is then injected hypodermically, the dose being one thirty-third of a grain, preferably over the triceps region, to ensure rapid absorption. Twenty-five minutes later the pulse is again counted minute by minute, until it is clear that any rise which may have followed the injection has begun to pass off. The difference between the average pulse-rate before the injection and the maximum reached after it gives the "escape," or acceleration of the pulse rate, brought about by the dose of atropine. If the escape is 14 or less the case may be regarded as one of typhoid or paratyphoid fever. If it is 15 or more, the reaction is said to be negative, and the test must be repeated after two or three days, and then again if it is then negative. Captain Marris holds that three negative reactions falling within the first fortnight of a febrile illness exclude the typhoid group with a considerable degree of certainty; there are rare exceptions, but in them a continuation of the tests is usually suggested by the symptoms and remaining clinical signs. Negative reactions after the fourteenth day or after the fever has fallen are often unreliable. In a series of 111 cases proved by bacterial culture to be of the enteric group, 94 per cent. gave a positive reaction to the first atropine test applied to them. Captain Marris has used atropine as a test in over a thousand typhoid suspects; he believes the results of its use to be trustworthy from the fifth day of the disease to the end of the second week. A positive reaction has been found as late as the 110th day. A series of negative reactions immediately after the fourteenth day is on the whole to be taken as evidence that there is no typhoid infection. A positive reaction may be obtained in men aged 50 or more who have not got typhoid, particularly if they are arteriosclerotic. In febrile patients with a pulse-rate of 100 or more a positive reaction (or failure of the heart to quicken fifteen beats or more) is to be judged cautiously and the test should be repeated. Similarly, a negative reaction in toxæmic patients who are very ill may be regarded lightly. Six proved typhoid carriers all gave negative reactions; contrariwise, prophylactic T.A.B. injections are apt to produce positive atropine reactions in a day or two. It must be remembered that Captain Marris's observations apply to patients almost entirely young men seen under the conditions of active service; yet it can hardly be doubted that the test will be found equally trustworthy among patients of both sexes and similar ages in civilian practice. The simplicity of the method puts it

at the disposal of all clinical observers, and it appears to be devoid of danger. Particularly interesting is Captain Marris's account of the *rationale* of his test. He has been led to conclude that the bacterial poisons of microbes of the enteric group, in contradistinction from those of other microbes, exert a depressing effect directly upon the intrinsic rhythm centre of the heart, at the same time blocking the vagal control of the latter. Atropine inhibits the vagal slowing of the heart; but in the typhoid fevers atropine fails to accelerate the pulse-rate much because the heart itself is poisoned. He finds that the normal quickening of the heart-beat by the inhalation of amyl nitrite is much depressed in typhoid, and that the intravenous injection of small doses of adrenalin solution fails to produce the transient rise in systolic blood pressure seen in healthy men—perhaps in consequence of the action of the bacterial toxins upon the myoneural elements of the walls of the arterioles. It would seem that in Captain Marris's atropine test we have a most valuable addition to our diagnostic methods in pyrexias of unknown origin, that vast group of mild fevers brought to light by the war. We congratulate its inventor on the clinical insight that led him to its discovery and on the broad views he takes while indicating its applicability and limitations.

SAILOR BREAD-WINNERS.

No one who thinks for a moment about the matter can doubt that the country in large measure owes its present position as a belligerent to the courage and endurance of the officers and men of the Royal Navy and mercantile marine. There is a world shortage of food, both of cereals and meat, and the need for economy was never greater, but, so far, this country has not suffered any real privation in the matter of food. How it strikes one who has not been in this country for a year or two is illustrated by the remark of a Canadian officer on leave from France who, after a day or two wandering about London, said, "I should like to give any German, who believes the stories he is told about the starvation of England, sixpence to spend on bus rides in London." When the regulations with regard to the dilution of flour for the making of bread were first introduced a fear was expressed that it would have an injurious effect on the public health, and that in particular invalids would suffer. The general impression that these fears were groundless, and that in fact the new bread is, on the whole, more wholesome than our old white bread, is fully confirmed by the discussion which took place last Monday at a meeting of the Medical Society of London. Dr. Robert Hutchison, while looking forward to improvements which the bakers could make as they gained more experience, said that it was certain there was nothing chemically injurious in war bread, and that it was in fact superior from a chemical point of view to white bread; any injurious effect that could be attributed to it must be due to its mechanical properties, but after fairly wide inquiry he was able to say that there was no real evidence of any serious disturbance of digestion by the bread in the majority of individuals; he added that he had himself seen no patient in whose case he was convinced that the bread had affected the digestion unfavourably. As to invalids, Dr. E. I. Spriggs, who is the medical director of Duff House sanatorium (mainly for digestive diseases), said that he had not found it necessary in any case to order white bread. There will be a shortage of meat for the next year, certainly if the war continues so long, and probably even if it ends; but though this will be inconvenient and distasteful to many people there seems no probability of its leading to any actual privation. Therefore we are free from any serious anxiety, from the point of view of the public health, as to the main elements in the national diet. We could not have been in this position but for the courage and self-sacrifice of the seamen. The debt of gratitude we owe to them can never be wholly paid, but

¹ National Health Insurance. Special Report Series, No. 9. London. 1917.

the King George's Fund for Sailors offers every one an opportunity of diminishing the debt, for the *Daily Telegraph* is making a special appeal in aid of this fund, and is ready to receive contributions of all amounts. Already, in response to this appeal, a sum of £30,795 has been received, and the total is growing from day to day. The main object of the fund is "to secure more efficient aid for the marine benevolent institutions throughout the kingdom, which have done so much for the mariner in the past, and whose resources have been greatly strained by the calls made upon them in the stress of war." That is an official statement of the purpose of the Fund.¹ Shortly, it may be said that it is hoped to place on an assured footing an organization which will do for sailors' charities what King Edward VII's Hospital Fund, London, has done for the institutions which tend the sick—attract to them increased sympathy and financial support, encourage them to work with greater efficiency, assist them to cut down management expenses, and generally to foster them so that they may fulfil their various missions with even more success than hitherto. The King, who has held an active commission in the Royal Navy, is patron of the Fund; Prince Albert, who is now on the active list of the Royal Navy, is its president; the Duke of Connaught is chairman; and among its warm supporters are the First Lord of the Admiralty, the First Sea Lord, Sir J. R. Jellicoe, and the Commander-in-Chief of the Grand Fleet, Sir David Beatty. It is certain that any money given to the fund will be well administered. The death roll of the Royal Navy already fills 383 closely printed pages of the *Navy List*, and over 6,000 sailors of the merchant service have given their lives in defence of these islands, and to ensure that the German purpose of starving us out shall not succeed. The merchant seaman, officer or man, is almost always a poor man, unable to make adequate provision for his family if he dies young, or for himself if crippled or prematurely aged. Not enough has yet been said of the courage and endurance of these men, which we all of us are inclined, with full justification indeed, to take for granted. It is only now and again that a light is flashed on their work by an official note or a chance conversation. The other day, talking on a wild moorland with an officer of the mercantile marine who had been thrice torpedoed, he said, "at first the submarine had to approach us on the surface, and then dived to get close enough to launch its torpedo. Now they keep much more under water, with only the periscope showing; that makes it much more difficult to spot them; it's like looking for a broomstick a mile away in that heather." Yet thousands of ships go out and thousands come into our ports every week, bringing us the necessities of life. The anxiety of every man on board them is terrible, the strain on the nervous system enormous, and the risks to life very great. It is our part to relieve them at last of the dread of poverty for their families, or for themselves when past service by reason of age, injury, or privation.

ALLIED CONFERENCE ON PENSIONS.

THE permanent committee of the allied conference on pensions, with delegates from each of the allied countries, assembled in London on October 9th, under the presidency of Dr. Bourillon (France). Before proceeding to business the committee was welcomed at Westminster House by Mr. John Hodge, Minister of Pensions, who recorded his conviction that the allied nations could not be engaged in a work of greater importance than that of repairing the bodily damage caused by the war. He said that in this country we had taken as our motto not so much the giving of pensions to our disabled soldiers as restoring them to useful membership of the community. Anything that

could be done to make disabled men even more productive, in spite of their disablement, than they were before the war was of great importance. A laboratory was about to be started for the improvement of artificial limbs with the aid of the best surgical advice, mechanical ability, and inventive genius. Anything found better than our own in an allied country would willingly be adopted, and our own improvements would be handed over with equal readiness to our allies. In conclusion, Mr. Hodge expressed the debt of the allied nations to the medical profession for the great work accomplished, not only in direct military surgery, but also for its efforts to restore those suffering from shell shock, wounds of the face, and other injuries. When history came to be written, he said, it would be a bright page in the annals of the medical profession. Sir Arthur Boscawen, Parliamentary Secretary to the Ministry of Pensions, announced that it was hoped to hold in London next year an inter-allied conference on the after-care of disabled sailors and soldiers similar to the conference held in Paris last May, and he invited the members of the committee to send representatives. A committee representative of all the allied nations was thereupon formed to consider arrangements for the conference. During the week visits have been paid to the military orthopaedic hospital at Shepherd's Bush, Queen Mary's Convalescent Auxiliary Hospital at Roehampton for soldiers and sailors who have lost their limbs in the war, and other hospitals, training institutions, and hostels, and inspections have been made of the work of War Pension Committees.

PSORIASIS AND TUBERCULOSIS.

PSORIASIS has long been regarded as one of the manifestations of that vague diathesis known principally in France as *arthritisme*. It is commonly held to be not incompatible with the best of health; in fact, it is only when, under treatment or otherwise, it subsides that substitution troubles such as asthma or arthropathy are said to arise. According to Professor Gaucher of Paris, however, its parentage is not as respectable as we have been asked to believe; indeed, it appears to have very disreputable relations. Starting with the remark that psoriasis is of frequent occurrence in tuberculous families, Dr. Gaucher inclines to the view that this skin affection is in reality one of the protean manifestations of tuberculosis. He found on investigation that a large proportion of subjects applying for the treatment of psoriasis had lost one or more parents (brothers and sisters) from pulmonary tuberculosis, while osseous and glandular tuberculosis was common among their collaterals. Then, too, the offspring of persons suffering from psoriasis display a proclivity to tuberculous meningitis, or, later on, to one or other form of local tuberculosis. Lastly, the subjects themselves succumb in an unduly large proportion to the pulmonary form of the disease, and, short of that termination, they are very liable to the manifestations of latent tuberculosis—asthma, enlarged glands, and the so-called tuberculous rheumatism. In short, although the evidence in favour of the tuberculous etiology of psoriasis is at present purely clinical, it is comparable to that formerly brought forward in support of the contention that lupus was a tuberculous manifestation, a hypothesis now admitted by every one. The point is one which practitioners might bear in mind in order to determine the frequency of the association of the two morbid conditions.

ACCORDING to a Home Office Order dated October 4th, among the classes of work which, under the Aliens Restriction Order, it shall be unlawful from October 15th for an alien in this country to perform, unless in possession of an identity book, is included: "Any work in a naval or military hospital, or medical organization, or in any auxiliary or voluntary hospital or medical organization affiliated thereto, or in connexion with the transport of members of His Majesty's Forces, or from the premises of any such hospital or organization."

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.

A GENERAL meeting of the profession took place at the rooms of the Medical Society of London on October 10th to discuss the best methods of promoting the second appeal of the War Emergency Fund of the Royal Medical Benevolent Fund and to nominate a general committee. This Fund was established last year to afford assistance to members of the profession who, in consequence of having taken a commission, find themselves in temporary financial difficulties. Lieut.-Colonel Sir ALFRED PEARCE GOULD presided over the gathering, and was supported by Dr. Samuel West, Colonel Charters J. Symonds, and Major G. Newton Pitt, respectively the President, Treasurer, and Honorary Secretary of the Fund. It was announced that sympathetic letters had been received from Sir Alfred Keogh, G.C.B., and Surgeon-General W. H. Norman, Medical Director-General, R.N.

Sir A. PEARCE GOULD explained that as a result of the first appeal made last year the sum of £5,000 was raised, and so far about £2,000 had been raised or promised as a result of the second. The object of the Fund was primarily to assist those members of the profession who, owing to taking a commission, had suffered so severely in their financial position that on their return to civil life they would find themselves embarrassed. It should appeal, in the first place, to those who could not say that their acceptance of a commission had materially affected their financial position; it should appeal also to members of the profession who were in rather more favourable circumstances than the majority of their brethren; and, finally, it should appeal to the large body of the public who were constantly dependent upon the services of the medical profession. In this connexion he hoped that medical men who were in a position to put the appeal wisely before the wealthy members of the general public would be encouraged to do so. The executive committee had asked for the sum of £25,000. If any such sum as that were aimed at, it was imperative that it should be raised before the war was over. The money would be invested, presumably in Government securities, which could be easily liquidated, but it would not be invested with the idea that the interest only should be used. The whole of the capital sum would probably be expended within two or three years after the end of the war. In any such benevolence as this the amounts given to individuals must be large; if a man had lost his all by accepting a commission and had to start again, it was of no use giving him a £5 note. This Fund was something which they owed to these men. Just as the wounded wore their gilt stripes as an honourable badge, so the man who sacrificed his position in civil life for the sake of his country was bearing all about his body the golden band of service, which gave him title to the special care and forethought of his fellows.

Major NEWTON PITT said that the appeals which were coming in at present were on a smaller scale and of less urgency than those they expected to get when the war was over. The committee had not yet made grants on the scale which would probably be necessary later when commissions came to be given up. Several funds existed whose function it was to assist officers. The Military Service Civil Liabilities Commission made considerable grants to officers up to the rank of captain; this was a Government fund, and in most cases where officers had applied they had been well treated, and in some the grants had been very large. The Officers' Families Fund was also of great value, particularly in caring for the education of officers' children. Then the new pension scheme would undoubtedly be useful for men who had been disabled, and it was possible for a junior officer to get a pension up to the amount of £175 a year. Each of these funds, however, only dealt with a certain special set of conditions. The first two funds he had named would cease to contribute after a man had given up his commission; so that while it was desirable that application should be made to these sources, their own fund had its quite definite function to fulfil. It was difficult to form any estimate as to the number of cases which were likely to require assistance, but seeing that 12,000 men held

commissions, an application for help from 3 or 4 per cent. of these—and the proportion would certainly be higher than that—would necessitate at least £25,000 if reasonable grants were to be made.

Colonel H. E. B. BRUCE-PORTER urged that the money should be offered as a loan; not, indeed, a loan to be tied round the beneficiary's neck, but a debt which he could feel himself at liberty to discharge—though not bound to do so—should be get on his feet again. He thought it wiser, also, to appeal for a bigger total. He hoped that £25,000 would not be their horizon.

Surgeon-General H. D. ROLLESTON thought that the loan principle would have the great advantage of making it easier for the feelings of the beneficiaries, but he quite saw that there might be practical difficulties in the way. He agreed also with the suggestion that the lay public should be asked to subscribe, but he was not prepared with any suggestion as to how that could be done except by the personal intervention of the practitioner.

Dr. J. F. WALKER (Southend) suggested the decentralization of appeals. The Divisions of the British Medical Association might be used for this purpose, and, if the secretaries were interested, a surprising volume of local subscriptions might be forthcoming.

Dr. CHARLES BUTTAR pointed out that Local Medical War Committees existed all over the country, and through these mediums it ought to be possible to find a man in each area sufficiently in earnest to run the Fund among his brother practitioners and the public.

Dr. SAMUEL WEST said that this Fund would begin to do its work where the other funds left off. In a very few instances the colleagues of an absent practitioner might not have "played the game," but apart from these rare cases men lost their practice through no fault of others. A practice was a personal thing, and if the practitioner was away, not for months, as they thought at first, but for years, the people moved away and various local changes occurred, so that the man returned eventually to find his practice cut down to nothing. The danger of overlapping (to which Dr. Buttar had referred) could be met by the consultation of a common register showing whether people had applied to other charities and with what result. The loan scheme was naturally attractive, but to his mind benevolence and money-lending were not compatible. The Professional Classes War Relief Council had originally a loan fund, but it was found after two years' experience that it was a failure, and that the loans virtually became gifts. He would suggest, however, that a practitioner might get a loan of £1,000 from his banker to enable him to carry on, and then there was no reason why the Fund should not give him the £50 or so required for the annual interest.

Major JOHN FAWCETT pointed out that a certain number of men in civil practice, as a result of the extra work they had had to do in helping their brother practitioners, had broken down and needed help equally with those who had gone on active service. He hoped that that aspect of the question would not be neglected.

Dr. WEST said that the Royal Medical Benevolent Fund had what they called an emergency fund (as distinct from the war emergency), originally designed to take the place of the old *Lancet* fund, which might be made available for such cases. Answering a further question as to the privacy of application, Dr. West said that a case was investigated by one of the officials of the Fund and a number was given to it, after which it appeared only as a number, and no one except the officials knew the name of the beneficiary.

Colonel CHARTERS J. SYMONDS said that no obligation would be placed upon a recipient to pay back what he had received, nor would the benefaction be cumbered with interest, but it would be open to him to return it as he thought right. The number of applications up to the present was 25, the number relieved was 18, and the amount expended, £300. The real stress, however, would come when the men were back and no longer had their army pay.

The meeting, before separating, agreed to the appointment of a general committee, consisting of not more than eighty names and representing every branch of the profession. The executive committee at present is identical with that of the Royal Medical Benevolent Fund.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Wounded.

Surgeon A. G. WILLIAMS, R.N.

ARMY.

Killed in Action.

CAPTAIN H. D. N. MACKENZIE, R.A.M.C.

Captain Henry Deedes Nutt Mackenzie, R.A.M.C., was killed in action on October 4th, aged 48. He was the third surviving son of the late Rev. C. H. N. Mackenzie, Rector of East Harptree, Somerset, and was educated at Bath College and at Edinburgh University, where he graduated M.B. and C.M. in 1893 and M.D. in 1897. He had since led a very varied life. He served as a civil surgeon in the South African war, receiving the medal; then as a plague medical officer in India and Egypt successively; was for a short time in the service of the Siamese Government, and in 1905 was medical officer in the Zanzibar Protectorate, and British consular officer at Peruba. He then went to New South Wales, and practised for some years at Corowa. At the outbreak of war he offered his services to the Serbian Government, and was the first British doctor to serve in Serbia. After some months there he was attacked by typhus, and invalided to England. In the summer of 1915 he served in France under the French Red Cross, and in October, 1915, took a temporary commission as lieutenant in the R.A.M.C., and was promoted to captain on completion of a year's service. He had since served in the Dardanelles, in Egypt, and in France, and when killed was attached to the Royal Field Artillery.

CAPTAIN J. P. PEGUM, R.A.M.C.

Temporary Captain Joseph Patrick Pegum, R.A.M.C., of Cahara House, Glin, co. Limerick, was killed in action on September 26th, aged 24. He was educated at Clongowes Wood College and the Royal College of Surgeons in Ireland. He took the diplomas of L.R.C.P. and S.I. in 1916, received a temporary commission as lieutenant in the R.A.M.C. at once, and went to France three months later. He was promoted to captain on completion of a year's service.

Died of Wounds.

CAPTAIN H. D. FIELD, R.A.M.C.

Captain Hassell Dyer Field, R.A.M.C., died of wounds on September 28th. He was the younger surviving son of Mr. Lascelles Field, of Thirlfield, Norbury, and was educated at Uppingham and at St. Thomas's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1914. After acting as resident medical officer of the Royal Victoria Hospital, Bournemouth, he took a temporary commission as lieutenant in the R.A.M.C. in April, 1915, and was promoted to captain on completion of a year's service. He went to the front in December, 1916.

Died.

Lieutenant and Quartermaster G. R. Lougher, R.A.M.C. (T.F.).

Wounded.

Colonel J. W. Houghton, R.A.M.C.

Lieut.-Colonel G. H. L. Hammerton, R.A.M.C. (T.F.).

Major G. N. Craig, New Zealand Medical Corps.

Major G. A. Heydon, M.C., Australian A.M.C.

Major W. W. S. Johnston, Australian A.M.C.

Captain G. W. Armstrong, R.A.M.C. (temporary).

Captain F. E. Johnson, R.A.M.C. (temporary).

Captain M. B. Lawrie, M.C., South African Medical Corps.

Captain G. N. Redpath, New Zealand Medical Corps.

Captain E. Scott, D.S.O., R.A.M.C. (temporary).

Captain C. P. Symonds, R.A.M.C. (temporary).

Captain A. C. Taylor, R.A.M.C. (temporary).

Captain W. Turner, R.A.M.C. (T.F.).

Lieutenant H. E. R. Altounyan, R.A.M.C. (temporary).

Lieutenant F. H. Fuller, R.A.M.C. (temporary).

Lieutenant W. P. S. Johnson, R.A.M.C. (temporary).

Lieutenant M. S. Munro, R.A.M.C. (temporary).

Lieutenant J. C. Pearse, R.A.M.C. (temporary).

Lieutenant W. B. Thompson, R.A.M.C. (temporary).

Nurse M. C. Hanning, V.A.D.

Nurse L. Stewart, V.A.D.

DEATHS AMONG SONS OF MEDICAL MEN.

Armstrong, Forster, Major Royal Field Artillery, son of the late Dr. J. F. Armstrong, killed September 25th, aged 41. He was educated at Giggleswick School and Christ's College, Cambridge, where he graduated LL.B. in the Law Tripos in 1899, afterwards qualifying as a solicitor. He got his first commission in 1902 in the 3rd Durham Volunteer Artillery, which later formed part of the 4th Northumbrian Howitzer Brigade, in which he became captain on February 24th, 1906. On November 14th, 1914, he was appointed adjutant of the Northumbrian Divisional Ammunition Column, and was mentioned in dispatches. Early in 1917 he was promoted to major and given command of a battery.

Dawes, Oswald Stephen Bernard, killed in action on May 8th, 1917, in France. He was the second son of Dr. J. W. Dawes of Longton, Staffs.

Graves-Burton, Richard Hastings, Commander R.D., R.N.R., youngest son of Surgeon-Major Graves-Burton, of Ealing, died suddenly at Portsmouth on September 29th, aged 49.

Hewkley, Francis Paget, Sergeant, Signal Company, Australian Imperial Forces, only son of Dr. Frank Hewkley, of Walbrook, E.C., died of wounds on September 26th, aged 23. Whilst holding a position with conspicuous bravery during an attack on Zonnebeke Ridge he was seriously wounded, and within half an hour was again wounded, fatally. He had served in Gallipoli from the first day of the landing until the evacuation. He was awarded the Military Medal for gallantry and conspicuous bravery under fire a year ago.

Hillaby, Eric Crowther, Flight Sub-Lieutenant R.N., second son of Dr. A. Hillaby, of Pontefract, reported missing on July 6th last, now reported killed on that date, aged 19. He was gazetted to the R.F.C. in August, 1916.

Hull, Edward Cecil Gordon, Second Lieutenant Royal Field Artillery, elder son of Dr. Edward Gordon Hull, of Streatham Common, killed August 26th. He was educated at Streatham School, at the City of London School, and at King's College, London, where he studied divinity, and had passed for the B.D. degree. He joined the R.F.A. in 1915, was wounded in August, 1916, and returned to the front in July, 1917.

Richards, Charles Morgan, only son of Dr. Morgan Richards of Fremantle, Western Australia, killed September 21st, aged 20.

Rieu, Charles, Sergeant Middlesex Regiment, attached Intelligence Department, second son of the late Dr. Charles Rieu of London, W., killed September 13th, aged 42.

Rose, George Douglas, M.A., Second Lieutenant Gordon Highlanders, second son of Dr. Rose of Aberdeen, killed September 20th, aged 22.

Wright, Noel Stafford, Sub-Lieutenant R.N., son of Dr. Southey Wright, The Firs, Wook, Dorset, killed September 18th, aged 18. His seniority was from January 21st, 1917.

MEDICAL STUDENT.

Murphy, George, Second Lieutenant 13th Royal Warwickshire Regiment, attached to the 15th Lancashire Fusiliers, killed in action, was the second son of Mr. George Murphy, of Bolton. He was a medical student at Birmingham University, and on the outbreak of war obtained a commission in the Royal Warwicks from his O.T.C. He was sent to Egypt and was there attached to the Lancashire Fusiliers, and became an expert in the use of the Lewis gun. He was sent to France at the beginning of this year, and while leading his platoon in an attack on September 6th was mortally wounded.

Nurse Daisy Kathleen Mary Coles, V.A.D., was killed by enemy aircraft on September 30th. She was the only daughter of Mr. Walter G. Coles of Glasgow, and received her training at Leith Infirmary. She had served in the Royal Victoria Hospital and at Craigleith Military Hospital before she went to France last June.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

AN Army Council instruction has been issued on the medical treatment and training for industrial life of discharged soldiers. So long as inpatient treatment is needed and accommodation is available, soldiers will be retained in appropriate hospitals. On the termination of such treatment, if the man is considered to be unfit for further service, he will be brought before an invaliding board, but will not be discharged from hospital until the actual date of discharge from the service—that is, twenty-one days after the discharge has been approved by the invaliding board. This procedure will be followed in the cases of all soldiers in hospital who are about to be discharged on medical

grounds, except in limbless and mental cases and cases of tuberculosis who accept sanatorium treatment. When a soldier has been approved for discharge, and when subsequently discharged, out-patient treatment may, if required, be suitably offered at a military hospital or in a Voluntary Aid or Red Cross auxiliary hospital. A course of technical training may also be desirable for many of the cases, and the provision of means for such training rests with the Ministry of Pensions.

The American Ambassador, on October 4th, opened St. Katherine's Lodge Hospital for American and British officers, situated in Regent's Park, London. Mr. and Mrs. William Salomon have lent the premises to the American Red Cross and have undertaken to equip and maintain them as a hospital for forty orthopaedic cases. Mr. Page, in declaring the premises open, said that in this hospital American orthopaedic surgeons would develop that method of surgery under the great leadership of Sir Robert Jones. Among those present at the opening ceremony were Surgeons-General Sir Alfred Keogh, Sir George Makins, and Sir Francis Treherne. The nucleus of the medical staff will be Captain F. Kidner and Captain Willard, members of the United States orthopaedic unit now in England. The nursing staff will consist of American Red Cross nurses.

England and Wales.

THE COLLEGE OF AMBULANCE.

THE fourth year of the College of Ambulance was opened on October 8th by the Bishop of London at the College premises in Vere Street, Marylebone. Colonel James Cantlie, F.R.C.S., the principal, described how the idea of a central institute for ambulance instruction in London had developed out of the classes he conducted at the Regent Street Polytechnic in the early part of the war. The College was a teaching body and nothing else, and since its foundation the number of complete first-aid courses given was 106; of courses in nursing, 75; and in camp hygiene and sanitation, 40. In those three subjects alone 1,160 lectures had been given; in addition lectures were given on many special subjects and frequent ambulance demonstrations. The students who had received instruction exceeded 14,000 and were now to be found in every part of the war area. The institution had been the cradle—or the kindergarten—of the Friends Ambulance Unit. At a time when the Second Army took over from the French a district in which typhoid was rife among the civil population, that unit dealt with the infected area, and nursed and fed and segregated the people to such purpose that not one British soldier was infected as a result of the new occupation. It was hoped to establish the college permanently as the head quarters of ambulance teaching in England, and to that end a number of governorships and fellowships were being instituted. The Bishop of London said that he was trying to get the military authorities to raise and take out a "Parsons' Ambulance Corps" for front line service. Sir Malcolm Morris paid a whole-hearted tribute to the work which Colonel Cantlie had done in the Red Cross and ambulance service for the last forty years; and Colonel Professor J. G. Adami, of Montreal, added a further eulogy, and said that ambulance work must continue after the war not merely as a part of the preparation in the event of another, but as a necessary element of the training in British citizenship. The bishop then distributed the college fellowships and demonstratorships, after which there was a display of stretcher drill by both men and women. Visitors also had an opportunity of inspecting the lecture and class rooms and museum on the three floors which the college has at its disposal. In addition to the anatomical models and first-aid appliances, a very large model was on view, which covered the whole of one side of the building, illustrating the medical arrangements on the field of battle.

THE TREATMENT OF INVALIDED SOLDIERS AT VOLUNTARY HOSPITALS.

The position of the honorary medical staffs of voluntary hospitals in undertaking the care of invalided soldiers under arrangements with the Ministry of Pensions was considered at a meeting held at Crewe on September 29th. The meeting was summoned by the County of Cheshire Local Medical and Panel Committee, and was attended by

the officers of that committee and representatives of the honorary medical staffs of voluntary hospitals in Cheshire, with several in Lancashire, and Dr. Marsh, Chairman of the Panel Committee, was voted to the chair. The Honorary Secretary of the Medical Board of the Warrington Infirmary wrote that the board of management had arranged to undertake the care of discharged soldiers in the hospital on the terms proposed by the Ministry of Pensions, and had decided to allocate 10 per cent. of the sum received to the honorary medical staff. Dr. Park, of the District Infirmary, Ashton-under-Lyne, proposed (1) that whatever charges the governors of hospitals see fit to make for the use of their buildings and equipment should be paid to them by the Pensions Committee; (2) that the members of the staff of these institutions be paid for work done by the Commissioners according to their schedule. The Chairman seconded these proposals *pro forma*, but pointed out that the operations referred to in the schedule of the Commissioners were only such as come within the scope of a panel doctor's duties, and the schedule was therefore inapplicable to treatment for which hospital attendance is necessary; and, further, that the Insurance Commissioners had no connexion with this matter of hospital treatment, which was in the hands of the Ministry of Pensions. After some discussion, the proposals were by consent withdrawn, and the following two proposals suggested by the British Medical Association were unanimously adopted:

1. That the services of the medical profession should not be given gratuitously to patients who are maintained by public funds.
2. That from all payments received by the governing body of a voluntary medical institution from the State or local authority a proportion, to be agreed upon between the governing body and the honorary medical staff, should be placed to a special fund which shall belong to the honorary medical staff.

After discussion the following scale of charges was unanimously adopted:

	£	s.	d.
Major operation, including anaesthetists' and assistants' fees	7	7	0
Minor operation with general anaesthesia, and including anaesthetists' fee	2	11	6
Anaesthetists' fee where the assistant is not a salaried resident medical officer	1	1	0
Minor operation with local anaesthetic	1	1	0
Attendance on in-patients, after operation or otherwise, for each week	1	1	0
(For less than a week in proportion.)			
Attendance on out-patients:			
Initial consultation	0	7	6
Each subsequent attendance	0	2	6
Report when required	0	5	0
X-ray examination, according to case—			
10s. 6d., 21s., or	2	2	0
Electrical treatment, x-ray treatment, or ionization (initial consultation)	1	1	0
(Each subsequent sitting)	0	2	6

It was further resolved to submit these resolutions to the various hospitals concerned and to the Ministry of Pensions and the county pensions committees, and to communicate them to the honorary secretary of the Lancashire and Cheshire Branch of the British Medical Association.

Scotland.

On September 29th a memorial to the late Dr. William Grant MacPherson was unveiled at Bothwell, where he had practised for nearly thirty years.

GLASGOW MILITARY HOSPITALS.

On October 2nd Field Marshal the Duke of Connaught visited a number of hospitals in Glasgow and district. After going round the military hospitals of Stobhill he went on to the Scottish National Red Cross Central Hospital at Bellahouston, where he was received by Sir George T. Beatson, K.C.B., chairman of the Scottish Branch of the Red Cross Society, and Sir Hector Cameron and Lieut.-Colonel Chaffer, commanding officer of the hospital, as well as members of the resident and visiting staff, were presented to him. After going through one of the medical wards the Duke went to the orthopaedic department, surgical wards, operating theatres, x-ray room, and electricity and massage departments. In the manual

curative workshops, where about one hundred patients are engaged in carrying out this stage of their treatment, the object of the training in wood carving, art metal work, joinery, boot repairing, tailoring, and other handicrafts was explained. There are at present 844 patients in the hospital, and the total number treated since its opening in October, 1915, is 7,560. Finally he visited the Erskine Hospital for Limbless Sailors and Soldiers, opened last June; there he was received by Mr. John Reid, vice-president, and Sir William Macewen, chairman of the House Committee, by whom he was conducted over the wards, operating theatre, x-ray room, research laboratory, and the temporary pavilions.

EDINBURGH TUBERCULOSIS FARM COLONY.

At a recent meeting of the Public Health Committee of the Edinburgh Town Council Sir Robert W. Philip made a report on the tuberculosis farm colony. He stated that at the end of the quarter there were in residence twenty colonists—twelve men and eight women. The health of the colonists had been generally good and the final results for the most part satisfactory, but the want of preliminary training in graduated work among the colonists received was an obstacle. The colony had been visited by representatives of the Pensions Ministry, the Local Government Board in England, and other authorities, and the National Association for the Prevention of Tuberculosis had, in issuing an appeal for the foundation of a farm colony for tuberculous sailors and soldiers, cited the results of the Edinburgh farm colony in support of the plan.

EDINBURGH CHILD WELFARE SCHEME.

The Public Health Committee of the Edinburgh Town Council has agreed to purchase Gogar Burn House and grounds to provide a centre for the Edinburgh child welfare scheme. The purchase comprises a large mansion house and fifty-seven acres of ground, at present largely under grass. The house will be adapted to accommodate about 150 children, the primary object being to make it a place for recuperation and preventive treatment. The necessary alterations are to be put in hand at once.

Ireland.

A COMMITTEE has been formed in Dublin, with Sir Robert Wood, F.R.C.S.I., as honorary treasurer, and Mr. Trevor N. Smith, F.R.C.S.I., 8, Upper Fitzwilliam Street, Dublin, as honorary secretary, to assist Dr. J. F. C. Meyler, of Dublin, who is unable to earn a livelihood and in very embarrassed circumstances. He has completely lost his hearing owing to specific disease contracted during an operation.

SALARIES OF DISPENSARY MEDICAL OFFICERS.

The Swinford Board of Guardians (co. Mayo) has received an application from its medical officers demanding an immediate increase in their salaries and the fixing of a graded scale of increments. In connexion with this application the medical officers submitted the following considerations: First, the present salaries were fixed more than a generation ago, when the value of money was much higher than in recent years; the actual worth of the remuneration has consequently declined considerably. Secondly, the demand for a graded scale is justified by the obvious fact that the experience and skill acquired in years of practice enhance the worth of a medical man's service to the community. For these two reasons many unions, prior to the war, readily granted their medical officers an increase of salary in proportion to their length of service. At present the overwhelming majority of all the unions of the country have adopted this course. A demand which was just and reasonable a few years ago has now become an urgent necessity. The cost of drugs, surgical appliances, and the means of locomotion, has increased enormously. This has, of course, to be met out of fees, most of which are now eaten up by such extra expenses. Hitherto the medical officers have borne the loss out of their own pockets. This drain upon their resources is quite apart from the increased cost of living, which they have also to face, like the rest of the community. In

the circumstances they have postponed action until the last possible moment, but the time has now come when they are compelled to press their demands by every means in their power. Were their claim granted, only a portion of the burden would be lifted from their shoulders. While willing to share it they are not willing to bear it all. The medical officers go on to state that in the event of the Board being unable to agree to the suggestions of the County Medical Committee a new scale of fees will be brought into operation on November 1st in the respective districts, as follows: For treatment and medicine at the surgeries, 5s.; for visit and medicine, £1; for maternity cases, £2. They hope, however, that they may not be driven to this course. The recommendations submitted involve only a small addition to the rates, but would prevent the cost of treatment in sickness from falling too heavily upon the ratepayers individually. A committee of the board of guardians was appointed to meet on a fixed date to consider the question.

Correspondence.

THE WOUNDED TERRITORIAL MEDICAL OFFICER.

SIR,—Now that the pay of the rank and file of the army has been improved, could not the attention of the authorities be drawn to the hard case of the misguided Territorial and Special Reserve officers who gave their services to their country before the outbreak of war?

In my own case, after several years of combatant service, I joined the R.A.M.C.(S.R.) immediately Lord Haldane asked medical men to support his Special Reserve scheme. On the outbreak of war I spent many weary months training newly joined men and officers, the latter receiving higher pay than myself. On active service the difference in pay was so small that one did not worry much, but early in this year I received a severe wound, which has kept me many weeks in hospital, and will keep me many more. While in hospital my expenses are very little less than when on active service, but my pay falls to 15s. 6d. a day, while a brother officer of the same rank, who is in the same ward with me, who is several years junior to me both professionally and in the service, is receiving 24s. a day.

I am aware that a biblical precedent has been quoted for this injustice, but in that rather notorious case the late comers received no more than those who had borne "the burden and heat of the day."—I am, etc.,

October 3rd.

A MARRIED MAN.

SIR,—With reference to the letter in the JOURNAL of September 22nd from "Captain R.A.M.C.(S.R.) Three Years' Service" regarding the pay of Special Reserve and Territorial Officers, the difference between them and the temporary commissioned medical officers is strikingly exemplified in my own case. I have recently been invalidated home from France, the result of an injury sustained whilst under shell fire, and have close upon eleven years' service in the Territorial Force, including two years in France with the B.E.F.

On coming home my pay is now about £50 a year less than the temporary officer who possibly only took up a commission a few months ago. I might also add that I have been nineteen years in practice, and on mobilization in August, 1914, I had in common with so many of my Territorial brethren to submit to the loss of the greater part of it. In my opinion the payment of our war bonus yearly instead of having to wait until the end of the war is a much needed remedy.—I am, etc.,

September 26th.

CAPTAIN R.A.M.C.(T.F.).

PANEL COMMITTEES AND THE ASSOCIATION.

SIR,—Dr. H. B. Brackenbury, in one of the forensic efforts that seem to give him so much pleasure, has the following: "The Association hopes to do better . . . it hopes to prove its case, and, if supported by Panel Committees, to ask for ten shillings for all insured persons."

"Its case," not the case of the Panel Committees. But it is claimed in a recent pronouncement that the Insurance

Acts Committee is directly representative of Panel Committees. Let us examine this statement. There are fifteen members of the committee nominated by Panel Committees, and the other twelve elected members are selected by the Representative Meeting on a geographical basis. It is claimed that as the majority of these electors are panel men, therefore the majority of the twelve are panel men.

The Committee has power to deal with all matters arising out of the Insurance Act, but it has got to report to the Council and through it to the Representative Meeting.

Now, the natural and direct method of representation of insurance practitioners is through the Panel Committees. This is recognized by every one, and therefore we find Dr. Brackenbury and those who agree with him claiming that the Insurance Acts Committee, as at present constituted, directly represents Panel Committees. This opinion is neither held by every member of the Association nor by all Panel Committees, and the number who are in opposition are sufficient to weaken the unity of action of the profession.

We have already three bodies in the field claiming to represent insurance practitioners—the British Medical Association, the Panel Medico-Political Union, and, lastly, the proposed Panel Association. The existence of the last two is a criticism of the first. It surely behoves every one to study the situation, for unless we secure unanimity under a strong control body we are bound to be weak and ineffective in the coming fight—a fight that will tax all our medical statesmen to their utmost in securing good terms for the profession while at the same time safeguarding the welfare of the community.

I would lay it down as axiomatic that there is only one possible Central Body—namely, the British Medical Association. It is not perfect in constitution, but it holds the field, and is determined to hold the field. It has shouldered a Federation of Panel Committees, and it will do the same with the proposed association, for its claim to represent Panel Committees is incompatible with the existence of any other body. But can this claim be justified on democratic grounds? I submit it cannot. Only half the members of the Insurance Acts Committee are directly representative of Panel Committees, and these are nominated. The other twelve are appointed on a geographical basis by—the Representative Meeting. It is alleged that because the majority of representatives are panel men, therefore the majority of those elected are the same. Are our leaders really satisfied with this? I doubt it. They are too shrewd not to recognize the risks of such a situation.

We are asked to close our ranks behind the British Medical Association, and we panel men are reminded that we are primarily members of the profession. Yes, but there are other associations within the British Medical Association—for example, Public Health Officers, Poor Law Medical Officers, and Medical Women, and these act in direct co-operation with the parent Association.

One approaches a region of surmise as to why it should be impossible to have an association of panel men inside the Association. Let that pass. It is, at any rate, a fact that the present method of representation is undemocratic and partly indirect. Now, it cannot be too often reiterated—we must have unity to have efficiency. I submit it is the undemocratic and inadequate representation of Panel Committees on the Central Body that is the main cause of the canker in our midst. I would therefore appeal to our leaders to remove this cause of discord, which is the cause also of rejoicing amongst those who have no love for the profession. The outside critics of the profession are already saying the British Medical Association does not represent panel practitioners, and any one can imagine what a weapon such an argument would be in the hands of opponents in Parliament and the press.

Can democratic and direct representation of Panel Committees be secured within the constitution of the Association? I hold it can. The principle has already been conceded that Panel Committees represent panel men. It logically follows that the central representative body, that is, the Insurance Acts Committee, should be composed mainly of representatives of Panel Committees. I suggest, therefore, that the members of the Insurance Acts Com-

mittee should consist of, say, twenty-five directly representative of Panel Committees, with four or five *ex officio* members, and the same co-opted members as at present. If this were secured, it would cut the ground from under the feet of those who are antagonistic to the Association as such. It could then be claimed—and truly claimed—that the Panel Committees are directly and democratically represented.

If this is not done, a very considerable and active minority will be left with a grievance, and continued sectional action will weaken our unity of action. After all, the British Medical Association stands for democratic representation, and is not a bureaucratic body. The principle here urged has been conceded; it remains to apply it in its entirety.—I am, etc.,

October 7th.

CHAS. FORBES, Captain R.A.M.C.T.

PANEL PRACTICE AND REMUNERATION FOR DRUGS AND MILEAGE.

SIR,—The time is rapidly approaching when practitioners' panel agreements will have to be signed for 1918, and it is therefore an opportune moment to consider the question of adequate and fair rates of payment for drugs and mileage under the present war conditions, as the existing rates are not only inadequate but unjust to the practitioner in these times of inflated prices.

With reference to the rate of pay for dispensing, the scale is on a pre-war basis. The cost of drugs and accessories has, like everything else, increased enormously. The chemists, on the other hand, who dispense panel prescriptions, are paid per item at a scale revised and brought up to date monthly, yet doctors are having to supply the same things to the patients for whom they dispense at the flat rate based on the pre-war prices.

With regard to mileage, each Insurance Committee was credited with an ear-marked grant to meet the mileage claim in its particular area. This grant is a pre-war one. Since then the price of petrol has gradually risen, and is now costing between 4s. and 5s. per gallon, which is more than double the price before the war; other expenses in connexion with the running and upkeep of a car have also increased proportionately. Obviously these rates of pay in the present exceptional circumstances are pressing unfairly and unjustly on the panel doctors, who have to bear the burden of these additional expenses.

Surely the time has now come when this obsolete scale of pay should be revised and adjusted to meet these increased costs, or a bonus be made to panel practitioners on a *pro rata* basis.

If the practitioners themselves do not put forward a demand for an increased remuneration, I can well understand that the Insurance Act Commissioners will not voluntarily suggest it.—I am, etc.,

October 9th.

OLD OCTOBER.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—Evidently the discussion of this subject is approached very differently by your various correspondents. One man's diagnosis is clouded with an ingrained suspicion of danger, and his prognosis is grave; another comes with an open mind and a leaning for moderation in all things; and yet another thinketh no evil, and his hope never faileth.

The finance of the scheme seems to be the special bone of contention, and that ominous word "inflation" has been made such a useful scapegoat that one may be forgiven for viewing it with continual mistrust as having still further capacity for service on behalf of the soldiers' fund. From Memo. 233, I.C. it would seem that this fund will be primarily fed with sums of 9s. a head per annum (29). In uninsured cases payment will be made to the fund from the Navy and Army Insurance Fund at the rate of 8s. 6d. (30). In insured cases the 8s. 6d. will come out of the General Medical Benevolent Fund, to which all sums available for their medical benefit will have already been carried (31). The fund will also be credited with a domiciliary sixpence, either out of the General Medical Benevolent Fund or the Navy and Army Insurance Fund (34). Now, if 9s. is paid in accordance with the above statements, then it must be obvious that there is 9s. to come out, and so much of this to us, let it be stated lest

we forget, as the dividend rate will amount to. This does not seem to support one of your correspondents in his statement that the deduction of 9s. from the General Medical Benevolent Fund entails a further depletion of 1s. 10d., nor does it support his contention that treatment by non-panel men entails the loss of 1s. 10d. per head to panel men. It is difficult to see how inflation can come in here. Still, it is a powerful word. The pessimist has no doubt of its capacity for evil and advises a radical cure; the moderate man will await events with faith in passive treatment and placebos; the optimist whose hope springs eternal has no qualms about the issue. The ability the Commissioners exhibit in the production of involved and redundant statements and regulations is really astounding, and one may well sympathize with the pathetic wonder of one of your correspondents, whether it would be of any avail if the Association begged for a reissue of the regulations in simple, plain, and unmistakable language. It is a vain hope: these things are sent to try us. That there are abundant reasons for misgivings in accepting at their face value these latest regulations, is only too well borne out by our experiences of the past. I am on the panel list of three counties, and it is interesting to note the varying deflating value of "inflation." I can give accurate figures for two counties for 1915. The medical credits for Montgomeryshire were: Treatment 6s. 2½d., drugs 1s. 2¾d., plus 5¼d. (transferred owing to this county having the lowest cost per head of prescriptions in Wales); total 7s. 10¼d. For Shropshire the credits were: Treatment 6s. 8d., drugs 1s. 7¾d.; total 8s. 3¾d. Although the Montgomeryshire County Committee sent into the Welsh Commissioners a strong resolution on the question of the medical credit for the county, with an explanatory letter from the clerk, who emphasized the fact that the register had been consistently kept free from inflation, we have derived no more satisfaction than a hungry man wandering in a valley of dry bones.

May I further draw attention to the manner in which the Commissioners' appreciation of inflation operates in the war-time scheme for the adjustment of the final credits in rural as compared with industrial areas. Obviously the proportion of the insured population available for enlistment in the former cannot be as great as it is in the latter, and to make an equal percentage reduction for inflation, based merely on the register, is unfair to the former. The following figures for Montgomeryshire bear this out:

July, 1914 ...	8,551 men	4,018 women	= 12,569
October, 1916 ...	7,913 "	4,619 "	= 12,532
	- 638	+ 601	- 37

—I am, etc.,

Llansantffraid, Mont., Oct. 9th.

W. H. LEWIS.

SIR,—In spite of various illuminating letters in your columns, few men have yet thoroughly grasped the inequity (and iniquity) of the arrangements made for defraying the cost of attendance on these disabled men, and the "explanatory statement" in the SUPPLEMENT of September 22nd avoids the question entirely. Every member of the profession, whether working the Insurance Act or not, should be made aware that the principle pervading the Notification of Births Act crops up again here and will soon be firmly entrenched in our legislation—namely, that medical men must willy-nilly give a certain amount of gratuitous work to the State in order to save the pockets of the rest of the community. It is quite obvious from the new regulations that a certain portion of the fees paid for attendance on these disabled men will come out of the pockets of the panel practitioners, whether they be paid to themselves or non-panel practitioners. What proportion of these disabled men will be able to work and send in stamped cards for the first half of the year we do not know, but half would probably be a liberal estimate for the first few years, the proportion dwindling as time goes on until eventually none will do so. Let us take 1,000 men and assume that 500 send in stamped cards, then the General Medical Benefit Fund, which belongs to the panel practitioners (and chemists), will receive 500 contributions of 9s. = £225 and 500 contributions of 2s. 6d. = £62 10s., a total of £287 10s., whilst it will pay out to the invalided soldiers fund 1,000 × 9s. = £450, or £162 10s. more than it receives, and this £162 10s. is the

contribution of the panel practitioners (either in work or in fees paid to non-panel practitioners) towards the cost of attendance on each 1,000 disabled men, in addition to what they pay in taxation in common with the rest of the nation. The exact amount, however, is immaterial to the principle, for if only ten of the thousand failed to send in cards the panel doctor would still be bearing a special tax.

It is difficult to imagine a commercial proposal quite analogous to the "regulations" of the Commissioners, but I think the following is fairly so: I (representing the Government) ask certain provision dealers to supply me with a million pounds of cheese (of 1s. per lb. quality) at 1s. per lb., and explain to them in the contract that 1s. does not mean one shilling, but merely a "dividend rate," which may be 11d., 10d., or less according to the price of butter at the time. I also explain that most probably I shall not be able to pay even the dividend rate from my receipts, as none of my customers will be able to pay more than 9d. per lb., and a great many will be able to pay only 3d., but as I am inclined to be generous I will make up the difference between 9d. per lb. all round and the dividend rate. They say, "Well, suppose we accept your dividend rate; what about the 6d. in the case of all those who pay only 3d. instead of 9d.?" I reply, "That's all right; you pay that out of what I pay you for eggs; and, by the way, I intend to get some of this cheese from other dealers, and you will, of course, pay them for it at the dividend rate." I am afraid there would be "nothing doing," except, perhaps, language. Ridiculous as such a proposal would be to commercial men, the Commissioners have ordained that an almost precisely similar one shall be not only made to, but practically forced upon, the medical profession, brains and work taking the place of cheese in the contract, and the disabled men that of the customers. Such proposals are not made to commercial men, to lawyers, or to trade unions, but are reserved for men who are credited with lack of the gumption to understand them, the spirit to resent them, and the *esprit de corps* and ability to combine which would enable them to reject them and insist on something reasonable. Such a body of men is, apparently, the medical profession, and the complacent explanatory statement of the Chairman of the Insurance Acts Committee may well be quoted as a proof thereof, unless the rest of the profession dissociates itself from him.—I am, etc.,

Swinton, Sept. 23rd.

J. PRICE WILLIAMS.

SIR,—Since writing on the subject of the new regulations (p. 438) I have been assured on the best authority that the temporary resident insurance dividend rate of approximately 95 per cent., upon which the payment of accounts under the new scheme is based, is absolutely and definitely fixed for at least one year, and probably two, until record cards are again in use.

My opposition to the new regulations was based mainly on the ground that the temporary resident dividend rate was likely to fluctuate within wide limits from year to year, and that our payments under the new regulations would suffer accordingly. As this is not the case (a vital point in the scheme, but one which has not, I believe, so far been made clear), I do not propose to offer any further objection to the scheme as a war-time expedient. Other disadvantages—for example, the departure from the principle of payment by capitation and the extra clerical work entailed—are of a minor character and not in themselves such as to invalidate the scheme.

I still hold to the opinion that a capitation rate would be preferable, and we must endeavour to secure this when the experimental period is over.

The method of procedure by which these new regulations have been enforced without Panel Committees having been afforded opportunity for the adequate preliminary consideration of them raises questions of a wider nature, of which more will shortly be heard.—I am, etc.,

London, N., Oct. 2nd.

A. S. DOWNTON.

SIR,—I should like to answer the specific questions which your correspondents ask me.

Dr. Bell, referring to the Conference resolutions authorizing the Insurance Acts Committee to voice the opinions of Panel Committees in central negotiations, asks whether I think these resolutions conferred plenary powers to agree to anything the Insurance Acts Committee

liked. My answer is. Certainly not. We have always been careful in meeting the Commissioners to disclaim any plenary powers. We do our best to let Panel Committees know what is going on, and to consult them if possible. In the present instance we should like to have had more opportunity for doing this, but in our actions we relied not merely upon the general resolutions to which Dr. Bell refers, but particularly upon the more detailed resolutions laying down the directions of the Conference upon this particular subject. To these directions we have adhered very strictly throughout.

Dr. Gardner asks me whether he is to understand that there is to be no system of checking excessive attendance on these men. My answer is, Yes; that is exactly what Dr. Gardner and others are to understand. The profession is to be relied upon to give the men adequate and proper attendance, and every item of attendance is to be paid for at the insurance rate.—I am, etc.,

London, N., Oct. 7th.

H. B. BRACKENBURY.

LONDON LOCK HOSPITALS.

SIR,—A great deal of misapprehension seems to exist in both medical and lay minds regarding the position of the London lock hospitals, so, at the request of the board, I have been desired to write asking you to be so kind as to insert this explanatory letter in the hope that it will clear away any misconception that may exist.

The male and female lock hospitals, which were founded in 1746, have been the principal centres for the treatment of venereal diseases in England since that date, and on the coming into force of the Venereal Diseases Regulations, 1916, the Lock Hospital immediately applied for approval under the new scheme. This was granted by the Local Government Board at the close of last year and a grant in aid is now received at both institutions towards the work being done, but the lock hospitals have always dealt with large numbers of cases in addition to those treated within the London County Council area, and experience has proved during the last nine months that more than ever is the hospital called upon to deal with cases of venereal disease that do not come within the scope of the new scheme, which it must be remembered only applies to venereal diseases in their early and communicable stages.

After allowing for the grant in aid referred to above the hospital has to raise in voluntary contributions a sum estimated at over £9,000 per annum, and the board earnestly desire that the medical and the lay public should realize the true position of the lock hospitals at the present time, when an idea appears to exist that the hospitals are entirely supported by grants from the Local Government Board, an impression which may seriously damage any efforts to obtain the necessary funds to carry on the important work at both institutions.—I am, etc.,

J. ERNEST LANE, Major R.A.M.C.(T.),
Member of the Board of Management and Chairman
of the Medical Committee.

London, W., Oct. 4th.

THE AIR WAR.

SIR,—I think it right to take exception to a paragraph in the latter part of your recent leader under the above heading. You quote the conviction of those on the spot that the damage done to a hospital base on the French coast in a recent raid, during which an American surgeon was killed, cannot be considered to have been accidental.

I was near that spot when the lamentable event took place, and I went the round of these hospitals on several successive days. A hospital base it certainly is, but cheek by jowl with the hospitals lie ammunition dumps, cement works, reinforcement camps, and training grounds, and I cannot believe that it is right to conclude, because one hospital was hit, that it was definitely aimed at. Surely, with so rich a harvest spread beneath him, it is incredible that an enemy aviator would deliberately waste bombs on so poor a target. I cannot refrain from expressing this view because, at the time it happened, one of our own journalists actually stated his belief that this raid was evidently carried out in order to intimidate, or wreak particular vengeance on, our American allies.

Surely the tale of German barbarity is enormous enough

without our having to make this particular charge, which, on the grounds I have stated, appears to me to be unjust.—I am, etc.,

ALEX. MACPHAIL,
Captain R.A.M.C.(T.).

London, E.C., Oct. 10th.

Obituary.

DR. JOHN WILLIAM DAVIES of Ebbw Vale, who died on July 19th, in his 68th year, took an active part in the local affairs of that district. He was the eldest son of Dr. John Davies of Brecon, Abersychan, and Ebbw Vale. He was educated at Christ's College, Brecon, and received his medical training at Edinburgh University and Guy's Hospital. After practising for three years at Clun, Shropshire, he removed in 1880 to succeed his father as surgeon to the Ebbw Vale Steel, Iron, and Coal Co.'s workmen. He held the appointment of Medical Officer of Health to the Ebbw Vale Urban District Council for thirty-seven years, and was also district medical officer and public vaccinator to the Bedwelly Union, certifying factory surgeon, and school medical officer. The lately formed Maternity and Infant Welfare Centre, of which he was medical officer, had his warm sympathy and support, and he entered heartily into the arrangements being made for baby week in the town, but, unfortunately, did not live to see the accomplishment of his schemes in that direction. He took an active interest in military work, and was instrumental in the formation of the 1st Welsh Field Ambulance, of which at the outbreak of the war he was lieutenant-colonel. It was a keen disappointment to him that, in consequence of failing health, he was unable to undertake active service and was placed on the retired list. Dr. Davies leaves a widow and large family, one of the sons at present serving as captain in the R.A.M.C.

DR. JAMES MILNE of Wincobank, Sheffield, passed away in the early morning of September 25th with tragic suddenness. Dr. Milne was born at Keith, Banff, in 1866, and received his early education there. Later he entered Aberdeen University, graduating M.B., C.M. in 1888. For a time he practised in Wales, but eventually he settled in Sheffield in 1893. He conducted a large practice and was universally respected by his patients and medical brethren. He was a member of the Sheffield Medico-Chirurgical Society and an old and loyal member of the British Medical Association. He was an original member of the Attercliffe Medical Guild which was founded in 1906. His energies were devoted solely to his profession. He was of a shy disposition and took no part in public affairs. He was buried at Kimberworth on September 29th amid signs of general mourning. A large number of his patients and friends showed their respect by their presence at the graveside. He leaves a widow, two sons (one in the army), and a daughter.

Universities and Colleges.

UNIVERSITY OF LONDON.

MATRICULATION EXAMINATION.

At the matriculation examination last month 266 candidates were successful, of whom 32 were placed in the first division; 15 supplementary certificates were granted, of which 10 were in Latin.

UNIVERSITY COLLEGE.

Three public lectures will be given in the Chadwick Departments of Municipal Engineering and Hygiene and Town Planning, as follows: On Thursday, October 18th, on "The effect of the war on municipal engineering and public health," by Mr. H. Percy Boulnois, M.Inst.C.E.; on Thursday, November 1st, on "Sanitary work in the army," by Major Arthur J. Martin; and on Thursday, November 15th, on "Some general aspects of town planning after the war," by Professor S. D. Adshead, F.R.I.B.A. The lectures will begin at 5.30 each day.

UNIVERSITY OF GLASGOW.

At a graduation ceremony, held on October 8th and presided over by Principal Sir Donald MacAlister, the following degrees were conferred:

M.B., Ch.B.—"Maud C. Cairney, B. W. H. Fergus, J. B. D. Galbraith, K. J. A. Gillanders, W. M. Kerr, Elizabeth C. McHaffie, J.

Macleod, Alice J. Marshall, Margaret M. Morton, F. L. Richard, A. Riddell, S. M. Riddick, I. M. Robertson, Jessie N. Robertson, J. A. Stewart, J. T. Taylor, W. H. Wallace, J. P. White.

* With commendation.

Mr. J. S. Martin, who graduated on July 21st, gains the Brunton Memorial Prize of £10, awarded to the most distinguished graduate in medicine of the year.

CALENDARS.

THE *Glasgow University Calendar*¹ for the year 1917-18 appears in a modified form owing to the exigencies of the war. Notification, too, is made of the fact that the list of classes to be held this year can only be regarded as provisional, for the same reason. For the rest, the volume contains the mass of detailed information and the lists of names customary in these indispensable works of reference.

The *Calendar of the National University of Ireland*² for the year 1917 contains an account of the work of its three constituent colleges in Dublin, Cork, and Galway, and its recognized college at Maynooth, together with the lists of teachers, examinations, examination results, and so forth that constitute the bulk of useful publications such as this.

¹ *The Glasgow University Calendar for the Year 1917-18*. Glasgow: J. Maclebose and Sons. 1917. (Cr. 8vo, pp. 442.)

² *Calendar for the National University of Ireland for the Year 1917*. Dublin: Alex. Thom and Co., Ltd. 1917. (Post 8vo, pp. viii + 579.)

The Services.

INDIAN MEDICAL SERVICE.

THE Secretary of State for India again announces that a limited number of appointments to meet the indispensable needs of the Indian Medical Service will be made on the recommendation of a special selection committee; full particulars can be obtained from the Secretary, Military Department, India Office, Whitehall, S.W.1. Applicants must be between the age of 21 and 32.

Medical News.

THE vacancy to the chair of natural history in the University of St. Andrews, caused by the retirement of Dr. McIntosh, has been filled by the appointment of Mr. D'Arcy Wentworth Thompson, C.B., professor of natural history in the University of Dundee.

THE Joint Committee on Ophthalmology and Otolaryngology of the United States Medical Board has under consideration a scheme for the organization of a section on brain surgery. If necessary, schools under the direction of brain specialists will be established in Chicago, Baltimore, New York, and Philadelphia.

THE sixth edition of Sir Patrick Manson's *Tropical Diseases* is ready for publication. It has been revised and enlarged, and the sections on mosquitos, tsetse flies, and ticks have been brought up to date by Lieut.-Colonel Alcock, C.I.E., F.R.S., of the London School of Tropical Medicine.

DR. CHARLES JOSEPH MACCORMACK, one of the medical inspectors of the Local Government Board in Ireland, has been appointed inspector of reformatory and industrial schools, and medical member of the Prison Board, Ireland, in succession to Surgeon-General D. E. Flinn, who has retired after a long period of service.

AT a conference arranged by the British Hospitals Association, when the chair will be taken by Mr. H. Wade Deacon, Chairman of the Royal Infirmary, Liverpool, the Rev. G. B. Cronshaw, Chairman of the Radcliffe Infirmary, Oxford, will open a discussion on the increase of grants for the treatment of soldiers and the proposed payment for discharged soldiers. The meeting will take place on Thursday next, at 3.30 p.m., at the Westminster Hospital.

AT a meeting of medical practitioners in the York area, held on October 6th, a resolution was unanimously adopted protesting against the new regulations as to invalid seamen and soldiers issued by the National Insurance Commissioners and expressing the opinion that the regulations are unfair to both patients and doctors, and should be replaced by a system securing adequate attention for the disabled men and adequate remuneration for the practitioners attending them.

MR. SAMUEL CRADDOCK, who became a member of the profession by taking the diploma of M.R.C.S.Eng. in 1856, is just about to complete fifty years' occupancy of the office of coroner for North Somerset; for five years previously he was deputy coroner both for the northern and the eastern divisions of the county. Altogether he has

conducted some 3,000 inquests, and although he is now 84 years of age still continues to attend all inquests himself, notwithstanding the great area he has to cover and the remoteness of some of its districts.

THE general annual meeting of the Auxiliary Royal Army Medical Corps Funds will be held at the Royal Army Medical College, Grosvenor Road, London, S.W., on Friday, October 26th, when the Director-General A.M.S. will take the chair at 3 p.m. Officers of the R.A.M.C. Auxiliary Forces whose subscriptions shall have been received on or before Saturday, October 13th, are invited to attend. The Secretary of the Funds is Lieut.-Colonel E. M. Wilson, R.A.M.C., 124, Victoria Street, Westminster, S.W.1.

AT the opening meeting of the thirty-sixth session of the West London Medico-Chirurgical Society, held at the West London Hospital on October 5th, Dr. A. J. Rice-Oxley, having been inducted to the presidency by the retiring president (Dr. E. A. Saunders), presented the latter with the Keetley Memorial Medal, and expressed the appreciation of the society for his work during the past session. Dr. Rice-Oxley then delivered an address on "The medical man as portrayed in English literature," for which, on the proposal of Dr. Clippingle, seconded by Major McAdam Eccles, he received a hearty vote of thanks.

AT a special meeting of the London Panel Committee on October 9th to consider the provisional regulations relating to medical benefits of invalided seamen, marines, and soldiers, it was resolved to approach the Commissioners in order to obtain the immediate withdrawal of the regulations. A resolution was adopted advising practitioners on the panel for the County of London to notify the Insurance Committee that they are not prepared to accept discharged and invalided sailors and soldiers on their lists under the terms of the new regulations, but that they are prepared to agree to the reinstatement of discharged and invalided sailors and soldiers on their lists in accordance with the arrangement which has hitherto prevailed, and that they are prepared to render such men all necessary attention and treatment at the present capitation rate pending negotiations with the Commissioners for a more equitable scheme. A further resolution was also carried to the effect that a communication be addressed to the staffs of the principal London hospitals expressing the hope that they would urge upon the governors the necessity of restricting the services rendered to these patients to those of a specialist or consultative character and of dealing only with such cases as were at the same time under the general control of a general practitioner.

ON the occasion of the entry into office of the new Master, Dr. Charles Sangster, a service was attended by the Society of Apothecaries of London, on October 9th, at the church of St. Andrew-by-the-Wardrobe, Blackfriars. Among those present were the Wardens, Colonel Connolly, A.M.S., and Mr. Samuel Osborn, F.R.C.S., Surgeon-General W. B. Slaughter, Deputy Surgeon-General J. H. Jeffcoat, and Surgeon-Major E. Colson (members of the Court), Surgeon-General Sir George Makins, Dr. de Havilland Hall, Dr. Vincent Dickinson, Dr. F. S. Palmer, and Dr. H. S. French. The service was conducted by the Rector, the Rev. P. Clementi-Smith, and an address was delivered by the Rev. C. H. Sangster, son of the Master.

THE second number of *Recalled to Life*, the journal specially devoted to the care, re-education, and return to civil life of disabled sailors and soldiers, contains among other interesting matter a note by Mr. G. J. Wardle, M.P., on the attitude of the Labour Party to the question of the treatment of disablement caused in the war. The party, he says, desires that the best treatment should be afforded, and that every appliance ingenuity can devise or skill suggest should be devoted to the restoration and aid of those who have become disabled. It desires that by training and re-education they should be aided to become self-supporting members of the community, whether they were men having a special trade before they joined up but whose wage-earning capacity is capable of improvement by further instruction, or whether they had no special trade. Subject to there being no diminution in the standard of living, or possibility of the disabled man being used to defeat the objects of the trade unions, those bodies desire to assist the disabled man in every possible way to secure employment on remunerative work. If a disabled man is able to do the same work as others, the fact that he is in receipt of a pension must not be allowed to interfere with his receiving the same rate of wage; if he is not able to do this, arrangements must be made by joint agreement between trade unions and employers to protect both the man himself and those who are working alongside of him.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. **EDITOR** of the *BRITISH MEDICAL JOURNAL*, *Aitiology*, *Westrand, London*; telephone, 2631, Gerrard.
2. **FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.

3. **MEDICAL SECRETARY**, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES.

D. M. wishes to know of a useful and practical short work on chirepody and the minor diseases of the foot.

THE EFFECT OF QUININE ON THE EAR.

T. L. writes: A patient who some years ago suffered from ear trouble caused by guntire was advised by an aural surgeon never to take quinine even in small doses. Duty now calls him to West Africa, where the taking of quinine as a prophylactic is imperative. Is there any reason to believe that quinine has a permanent effect on the ear mechanism?

CEREBRO-SPINAL FEVER AND ITS TREATMENT.

CAPTAIN A. M. WATTS, M.D., R.A.M.C.(T.C.) writes: With regard to the letter from Dr. Alwyn Stewart (October 6th, p. 469), I should like to ask him what kind of serum he has been in the habit of using. He says that it has been his practice to give 100 c.cm. of serum intravenously, and in addition 300 c.cm. as the initial dose subcutaneously. Now the dose of the Lister Institute serum is 30 c.cm., and that of the Rockefeller Institute 20 c.cm., which is very much less.

I am anxious to know why he excludes from his corrected column of statistics "hopeless cases and those of 35 years of age and over." How does he define a hopeless case? Then, again, he uses lumbar puncture only in mild cases. What does he consider a mild case?

Serum he gives intrathecally, subcutaneously, and intravenously in certain cases which he says were all severe. May I ask what constitutes a severe case?

LETTERS, NOTES, ETC.

TREATMENT OF VINCENT'S ANGINA.

DR. PERCY NEWELL (Margate) writes: It is to be hoped that such a remedy as salvarsan, which Dr. Trotter describes (p. 469) as unsatisfactory and expensive for general use (he might have added also dangerous, will not come into general use for the treatment of Vincent's angina. The local application of tincture of iodine or liq. sodae, with potassium chlorate given internally, will cure all cases of the disease, without "burning down the house to roast the pig."

COMFORTS ON A LONG JOURNEY.

A CAPTAIN R.A.M.C. who has recently made a somewhat lengthy journey by train and boat, encountering hot weather on the way, sends the following notes for the benefit of inexperienced travellers:

1. Take a water bottle and lose no opportunity of filling it with drinking water; it must not be supposed that any

particular train, camp, or boat will have a sufficient supply to make this unnecessary.

2. Similarly with food. Always carry reserve food. It is better to eat badly in your tent than to wait perhaps hours for the official dinner.

3. You must have a canvas bucket if you want to wash; a bath packed in the luggage van or the hold is of no immediate value.

4. You will certainly need chlorodyne or cascara, and also toilet paper.

5. Some camps are several hot, dusty miles from the station or quay.

6. Every one but yourself is a born thief. Borrow all you can, lend nothing, and leave nothing lying about.

7. The following, most of which can be packed and kept in a large haversack, are necessary: A few thin books of the sort that can be read more than once, a tin mug, knife, spoon, and fork, a knife with corkscrew and tin opener, a pair of shoes (soft), washing and cleaning materials, writing material, a small clothes brush (also used for brushing seats of carriages, etc.), a trench candle.

8. According to taste, take also a pack of cards, a pound of tobacco or cigarettes, and not less than £10 in notes.

9. Always remember that you must depend on your own initiative to obtain such decencies and comforts as are available.

PYORRHOEA ALVEOLARIS.

DR. VAUGHAN PENDRED (East Sheen) writes: It is high time that a strong protest was raised against the very modern craze of pyorrhoea alveolaris. As a general practitioner I have seen many cases that have consulted physicians, with the result that if nought else could be found, the symptoms were referred to a pyorrhoea—in several cases, I regret to say, in my experience non-existent. I have seen several people rendered edentulous because of pyorrhoea, but in not more than 10 per cent. have I seen the slightest advantage gained. A lady was recently taken to a consultant for neurasthenia—all her teeth were removed, with the result that she has become a hopeless nervous wreck. Our profession is for ever flying off on some new scare that lasts perhaps three years and then dies, as, indeed, it as a rule deserves. Fortunately, the greater part of these crazes are harmless, but this is causing an infinite amount of sorrow and injury. The claim that pyorrhoea is the universal cause of everything that avoids diagnosis is too scandalously unscientific to need comment. Sometimes the removal of the teeth does good, but to sentence everybody on the discovery of some baneful microbe to have teeth removed—or all their teeth—is monstrous. It is gravely trying the general practitioner, who has a steadier, more equipoised, mind than the consultant. Twice recently I have injected autogenous microbic preparations for consultants without the smallest improvement of the symptoms.

BOMBING THE RED CROSS.

We mentioned last week that the French authorities are convinced that the Germans have deliberately employed aeroplanes to bomb advanced hospitals. *Le Journal* of Paris, which since the beginning of the war has published many excellent caricatures, printed at the end of last month a sketch by Raoul Vion, which we have ventured to reproduce. The legend is: "Kamarad; Kamarad; not the Red Cross!"

CORRECTION.

In the leading article on the treatment of cerebro-spinal fever in the *JOURNAL* of September 22nd there was an obvious misprint in line 39, page 394, where the word "fever" should have been "fluid."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postea* restant letters addressed either in initials or numbers.

Remarks

ON

THE TREATMENT OF INFECTED, ESPECIALLY
WAR. WOUNDS.

By RUTHERFORD MORISON,

PROFESSOR OF SURGERY, DURHAM UNIVERSITY; SENIOR SURGEON,
NORTHUMBERLAND WAR HOSPITAL.

If any one had told me two years ago that it would be possible to treat large infected wounds in such a manner that they required no special drainage, that they could be safely closed by sutures at any period of their progress, and that the dressings used for them could be left unchanged for from one to six weeks, with a knowledge that healing was making steady progress, I could not have believed it. There cannot now, however, be any doubt of all of these statements, because each one has been proved in hundreds of instances, not only by my cases but by those of others.

These results have been achieved, firstly, by thorough cleaning of the wound and its surroundings, and then the use of antiseptics.

The antiseptics are 1 in 20 carbolic lotion for the skin, cleaning with alcohol and the use of an antiseptic paste for the wound.

The following directions are those given by Sergeant Hunter, dispenser to the Northumberland War Hospital, for the preparation of the paste:

Preparation of the Paste (Bipp).

Iodoform 16 oz., bismuth subnitrate 8 oz., liquid paraffin 8 fl. oz., or a sufficient quantity. The powders are mixed together in a mortar, and the liquid paraffin incorporated. The quantity of liquid paraffin required varies according to the bulk of the powders, the bismuth in particular being liable to a considerable variation in bulk. A sufficient quantity should be added to form a paste. It is then advisable to rub down the paste, in small quantities at a time, on a slab with a spatula, to ensure freedom from grit and dry particles of powder.

I have called this paste "Bipp" because the name indicates its constituents and their proportions, and because a short title is convenient.

One drawback of this method, to which others as well as myself, in both of my published papers, have drawn attention, is the risk of iodoform and bismuth poisoning. (See also Case I.) In our earlier work we used the paste too generously, with the result that some patients suffered from absorption. Since smearing the surface of the wounds and rubbing in the Bipp, removing any excess, we have had no trouble of this sort.

Another drawback is that as iodoform and bismuth are both opaque to x rays, there may be difficulty in the discovery of foreign bodies and unsatisfactory pictures of fractures taken after the paste has been applied.

The method is not ideal—I have never claimed that for it—but the advantage to patients in saving of lives and limbs and suffering, and to those in charge of them in work anxiety and expense is so important at the present time that I feel no hesitation in repeating, to a large extent, what I have previously stated elsewhere.¹ The clinical, bacteriological, and chemical effects of this treatment have been dealt with in two papers² by Drs. Louisa Garrett Anderson, Helen Chambers, and J. N. Goldsmith, with such efficiency that it would be difficult to add anything to them.

My present object is to draw further attention to the technique, which though very simple is seldom carried out quite as I have suggested. It is certain that better methods will be, and may already have been, found; but some of the failures I have seen have clearly been due to faulty surgery and not to the method of treatment. About half of the patients in the latest convoys sent to the Northumberland War Hospital have been so treated. In spite of some incomplete successes all of my colleagues there are agreed that the best wounds by far result from it.

In my previous papers I have tried to emphasize the value of my method in fractures by records of cases and a statement of some results. Compound fractures of all the bones can now be treated with as great ease both to the patient and surgeon as simple fractures are.

Though it is desirable to see the bottom of all wounds, it may be occasionally unwise. A through-and-through

wound, with small entrance and exit openings, may be generally cleansed satisfactorily by passing a long strip of gauze through it and pulling this to and fro as a first step, next by doing the same with a strip of spirit gauze, and finally depositing a layer of Bipp on the inner surface of the wound by spreading a long strip of gauze with the paste, passing it through the track and rubbing in the medicament by pulling the gauze backwards and forwards again and again.

Dissecting out the wound is unnecessary, and in the hands of surgeons who are insufficient anatomists may be dangerous. The most that should be done in this respect is to remove only such portions of tissue as are obviously dead. The drier a wound can be made the better, but some haemorrhagic oozing does not bar success.

Several wounds bipped at the front have arrived here with drainage tubes or tissue drains or gauze packs in them, and most of them unsutured. Presumably this is from fear of gas infection, and this is too serious a question for any one not dealing with many fresh wounds to attempt to answer, and even with much opportunity it should take considerable time and careful handling. My own experience has been that the fresher wounds are the better they react to Bipp treatment, and I have now closed several without tube or other drainage than is allowed for between interrupted sutures, not too close together. From these the bacteriologist has cultivated *Bacillus perfringens*, tetanus, and a variety of other anaerobic organisms, but the results have always been good.

Silkworm-gut sutures appear to be favoured at the front, and for ordinary septic wounds I recognize that they are best. Thick sterile silk, soaked in tincture of iodine, or dry and rubbed all over with Bipp (for this hint we are indebted to Major Home of the New Zealand Army), is, I think, better for bipped wounds. Silkworm gut is more likely to cut through, and as sutures should be left for a longer time than ordinary, and take a larger, deeper bite of the tissues, silk seems more satisfactory. Especially when granulating surfaces are brought together union is slower than when fresh surfaces are joined, and if sutures be removed too soon, wounds which appear to be healed may open up again; therefore our rule is to leave the sutures for three weeks. For the skin alone, and as accessories, silkworm gut is efficient.

With very few exceptions I close the wounds with interrupted sutures, and even in those most acutely infected have seen no bad results. Indeed, it is especially in such cases that our greatest triumphs have been evident. (See Cases II and IV.)

After the first dressing has been removed, if the wound is clean, granulating, and superficial, we generally now discard Bipp and use ordinary daily dressing, which allows of more rapid healing.

We treat all our wounds with Bipp unless they are small, or superficial, or obviously doing so well as to be best left alone. In some instances, however, especially in cases of compound fracture of the femur which appeared to be so well as to require no heroic measures, we have had to regret this conservative attitude. A flare up later has necessitated free opening and the treatment which should have been undertaken earlier, before active, widespread infection made it both more serious and more difficult.

CASE I.—Case of Bipp Poisoning sent from the Front, with Multiple Wounds.

A private was wounded on June 22nd, 1917, by a shell. A note from France says:

"June 22nd, 1917. C. C. S., penetrating wound from radial to ulnar side, right forearm. Splinter punctures left hip, thigh, and foot. Abrasions right thigh and lower leg. Incised wound right scapular region. Forearm wounds excised. Foreign body removed. Elbow-joint opened; internal condyle chipped. Bipp.

"June 23rd. Two superficial wounds back closed over Bipp, three wounds, buttock explored; one small piece of metal found; track led to coccyx, which was fractured; third track led into glutei, but did not suggest penetration. All tracks were small; Bipp in each. Right elbow opened on inner side; wound excised with long fragment track, and joint filled with Bipp and closed."

On admission to the Northumberland War Hospital on July 16th, the note made was as follows: A fair, pallid, delicate-looking man of poor physique and with old pyrrhoea. No pain in any of his wounds. Over radial border of right forearm, 2 in. below the elbow, an incised wound, 2 in. long, covered with a scab, healed stitch marks on either side. Over flexor surface of right elbow-joint near ulnar border, a round wound size of a

* This is the type of patient most likely to suffer.

shilling, with Bipp in its depths and very little discharge. This lay in the centre of an inner wound, about 5 in. long, and healed in the rest of its extent and with stitch marks on either side. The remaining wounds were all in satisfactory condition. There was a blue line on the gums at the roots of all the teeth. Though the patient showed no general or local symptoms of poisoning, it seemed as if serious absorption of bismuth was probable.

CASE II.—Case of Compound Fracture of the Ankle-joint: Acute Infection.

A stout alcoholic woman of 60 was admitted to a private hospital on Monday, January 15th, 1917.

History.

On the Saturday night previous to her admission she was getting off a tram car and "went over" on her left ankle. She had great pain but managed to walk home, about five minutes' distance. The doctor who saw her found a compound fracture of the left fibula near the ankle joint. Her foot was lying on its outer side, and was placed backwards. X rays showed fracture of the left fibula $1\frac{1}{2}$ inches above the ankle-joint, fracture of the inner malleolus of the tibia, and displacement of the foot outwards and backwards.

The patient came under my care sixteen days after the accident. I am indebted to Dr. Eleanor Walkinshaw for these notes:

She never did well from the time of the accident (see Chart 1)—always complaining of pain in her leg and sleeping badly. I think it probable she would have developed delirium tremens but for a plentiful supply of egg and milk and rum.

Operation (by Professor Morison).

On January 31st the foot and lower part of the leg were swollen to double their normal size, the skin covering the lower third of the leg and foot was bright red and oedematous, and deep fluctuation could be felt.

A long incision—about 6 inches—was made upwards on to the leg and downwards on to the dorsum of the foot from the suppurating wound over the lower end of the fibula. From 4 to 6 oz. of pus escaped. The pus had burrowed upwards between the extensor muscles under the deep fascia and downwards into the ankle-joint. A portion of loose bone was removed from the lower end of the fibula, and the fracture was found to communicate with the ankle-joint. A finger in the ankle joint found the head of the astragalus bare. The edges of the wound

I thought it unlikely that she had any chance of recovery except by amputation, and I do not doubt that any surgeon would have agreed with such an opinion. I know of no other means which could have been used to save this life and leg.

CASE III.—A Fresh Gunshot Wound Treated with Bipp.

Notes by Dr. ELEANOR WALKINSHAW.

History.

The patient was brought in within six hours after having his foot badly lacerated by a shot from a sporting gun. He and his brother were walking together—the latter carrying a loaded gun muzzle downwards, which somehow went off and wounded the patient.

On Admission.

The foot was found to be badly lacerated, and the fourth and

fifth toes and a considerable portion of the outer part of the foot were missing. The jagged ends of the metatarsal bones were projecting into the wound. The second and third toes were damaged beyond repair, the soft parts being pulped and the phalanges fractured.

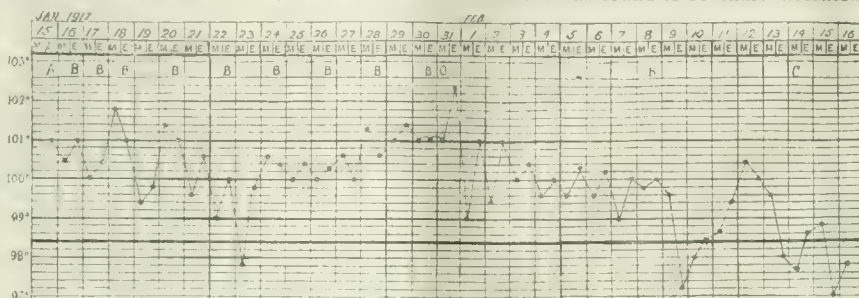

CHART 1.—Case II. A, Admitted. B, Aperiect. O, Operation. C, Wound dressed.

Operation (by Professor Morison).

Soon after admission amputation of the second and third toes was completed. The foot was trimmed up, and the projecting bits of the metatarsal bones were removed. The whole wound was dried, swabbed with spirit and bipped. The skin, some of it badly damaged, was sutured over under tension, with thick silk sterilized and steeped in tincture of iodine. The skin that was damaged and tense was scored all over.

After-Progress.

A fortnight after the operation (see Chart 2) the wound was dressed for the first time. The dressing was almost dry. The large inner part of the wound was healed, but at the outer portion where tension had been greatest and the skin most damaged, there was an area of 1 in. to $1\frac{1}{2}$ in. still unhealed. Bipp was applied again.

January 27th, 1917. Wound quite healed. Patient went home.

CHART 2.—Case III. A, Wound dressed; almost healed. B, Wound dressed; all healed.

were separated by retractors, and the whole of the infected cavity was exposed. It was carefully cleansed, first with dry gauze, then with spirit gauze, in every part of it. The whole interior was then scrubbed with Bipp, including the ankle-joint. The incision wound was closed with five thick silk interrupted sutures soaked in tincture of iodine, but the edges of the original wound could not be brought together. The wound was dressed with Bipp spread on sterile gauze, and over abundant cotton-wool two lateral Gooch splints were applied.

After-Progress.

The night after the operation was the best the patient had had since her accident, and she rapidly recovered her appetite, sleep, and health. (See Chart 1.)

First dressing, February 15th (fifteen days after operation).—There was very little discharge on the dressing, not more than $\frac{1}{2}$ oz. of dark, slimy, thick matter. The incision wound had entirely healed and the sutures were now removed. The original wound was dressed with Bipp, the leg was bandaged in plaster-of-Paris, and the patient went home.

Second dressing, March 15th (one month after the first).—The plaster was removed, the wound was found to be entirely healed, and the patient was sent home "cured" after her accident. In three months' time she was walking about well.

When I found the condition of this leg and heard the history of the patient's habits and general condition,

CASE IV.—Wound of Hand, Infection of Palmar Bursa probably through Tendon Sheath of Little Finger.

Notes by Dr. NORAH MURPHY.

A private, aged 19, admitted to the Northumberland War Hospital on July 16th, 1917.

History.

Wounded at Ypres on July 6th by shrapnel. Sent to casualty clearing station same day. Note states: "Fourth and fifth fingers removed, wound excised and fracture of carpus—bipped." First inoculation July 6th; second July 9th, because patient showed slight tetanic symptoms.

On Admission.

Hand.—There was an extensive granulating wound extending from the base of the thumb along the radial side of the second metacarpal to the base of the first two fingers down on to the palm and up as far as the wrist. The whole hand, excepting the thumb and index finger, which were fairly movable, was one large wound (see Fig. 1). The fourth and fifth fingers with the corresponding metacarpals had been removed—the third finger was dislocated at the metacarpo-phalangeal joint, and the metacarpal bone was fractured. The extensor tendon to this finger stretched across the dorsal aspect of the wound as a slough. The edge and granulations looked well, there was very little discharge, but on pressing the lower third of the forearm

some pus escaped from the upper part of the wound. The wrist-joint was slightly swollen and a little red. There was no oedema.

Head.—There was a small penetrating wound over the left malar bone; looked clean; had been bipped. Patient had a "black eye" on left side.

FIG. 1.—Condition of hand on admission (Case 1).

Thigh.—Along inner side of left thigh immediately above the internal condyle of femur there was a clean, granulating wound, about 5 in. by 2 in. in size; it had been bipped.

General condition of patient good, but temperature and pulse raised.

First Operation.

On July 20th the forearm was incised on the palmar surface just above the radial side of the wrist-joint; free communication with dorsum made. Bipping. No sutures. Small piece of loose bone removed from left malar.

July 26th. Temperature and pulse still high (see Chart 3). Hand fomented; free discharge of sero-pus.

Second Operation.

On July 27th the upper edge of the dorsal part of the wound was reflected, and about $\frac{1}{2}$ oz. of thick yellow pus let out.

The carpal bones were found to be embedded in pus; all removed excepting the pisiform, trapezium, and trapezoid. There was a tiny erosion of the cartilage over the lower end of the radius. Bipping. No sutures.

July 30th. Temperature and pulse still high. Face wound healed. Hand fomented. To be operated upon to-morrow.

Third Operation (first by Professor Morison).

On July 31st the wound on the flexor surface of the forearm was enlarged sufficiently to expose the whole of the palmar bursa. Good through-and-through communication made with dorsum of hand. Wound cleaned, first with dry gauze, then spirit gauze, and finally bipped gauze pulled through and Bipp rubbed in by to-and-fro movements of gauze. Wounds closed with thick silk sutures.

August 1st. Temperature normal, pulse 100. Patient very well.

August 7th. Temperature and pulse normal.

Fourth Operation (second by Professor Morison).

On August 10th an incision made along the ulnar side of the middle finger; phalangeal bones removed. The skin of the finger was turned down over the wound and practically the whole granulating surface covered (see Fig. 2), leaving only two

FIG. 2.—To show condition after operation. The crosses indicate stitches. The transverse marks on the transplanted flap represent scores into the skin to diminish oedema as an aid in the prevention of gangrene.

small areas about $\frac{1}{2}$ in. on uppermost edge uncovered by skin. The flap was sutured loosely with thick silk, and cross incisions made over the skin surface (see Fig. 2). Bipp gauze laid over the stump. There was very little bleeding on removing the tourniquet.

August 11th. Patient very well. No rise of temperature.

August 24th. First dressing after second operation (fourteen days). Dressing blood-stained, almost dry. No sign of infection of wound, and finger appeared to have healed over raw

area. Sutures undisturbed. (The dressing was done to show surgical visitors the case, otherwise it would have been left unchanged for another week.)

August 31st. Healed except for small granulating area size of a 3d. piece on dorsum at root of thumb. All stitches removed.

Gunshot wounds of the knee-joint are reported among the most serious injuries. My personal experience of them has been limited to wounds of some duration, so that I can only suggest a method for trial with Bipp.

Clean bullet wounds so often heal well that they are exceptions, and should be dealt with on ordinary lines. If the joint goes wrong, or the injury is complicated by a fracture, or the wound is due to large shell fragments, my treatment would be:

1. Apply extension strapping or glue dressing below the knee.
2. Disinfect the skin surrounding the wound and the joint (1 in 20 carbolic).
3. Apply a tourniquet.
4. Cover up everything except the knee with sterile and moist antiseptic towels.
5. Open the joint through a horseshoe-shaped incision, dividing the patellar ligament and the musculo-aponeurotic structures on each side of the joint, but avoiding damage to the lateral ligaments on either.

6. Reflect the patella, exposing the joint and subcutaneous pouch. Mop—gently, very gently, not scrub or wipe—with dry sterile gauze, any discharge from both.
7. Flex the joint fully, and clean the posterior portion of the cavity by gentle dry mopping.

8. Gradually

extend the joint; fill it with spirit and gently mop dry.

9. Remove the tourniquet with the limb elevated to a right angle, and keep it there with the joint compressed under gauze pads for four minutes. Then clamp any bleeding points with Lane's haemostatic forceps.

10. Rub a thin layer of Bipp over the whole joint surfaces with a finger. Rubber gloves are understood.

11. As soon as bleeding has ceased suture the patellar ligament with strong mattress sutures and close the remainder of the deep incision with interrupted catgut sutures, holding the joint capsule with interrupted sutures of fine catgut. Close the skin with interrupted sutures of thick dry sterile silk smeared with Bipp.

12. Dress the wound with gauze wrung out of spirit, and over this abundant cotton-wool but no bandage.

13. Fix the limb with two—inner and outer—Gooch splints, the inner reaching from perineum to sole of foot, the outer from tip of trochanter to sole. On top of the ordinary bandage apply an oblique one at the top, another above and below the knee, and one above the ankle, of plaster-of-Paris.

14. As soon as the patient is in bed apply a 15 lb. weight for continuous extension.

Unless there is need the dressing should not be changed for three weeks. As soon after as the wound is healed movements and massage should commence.

Preparation, Sterilization, and Keeping of Bipp.

Mr. Sidney Dunstan, chemist and dispenser to the Royal Victoria Infirmary, has supplied a note as to his preparation and sterilization of Bipp and for keeping it in very convenient tubes.

The method adopted by myself in making Bipp is as follows:

Iodoform	440 grams
Bismuth subnitrate	220 "
Paraffin	220 "
M.S.A.				

The bismuth and paraffin are sterilized by dry heat at a temperature of 120 C. for half an hour, the bismuth after

cooling is mixed with the iodoform in a mortar which has been sterilized by means of boiling water and formalin. The paraffin is added to the mixture at a temperature of 90° C. and thoroughly mixed, then put into specially made collapsible tubes with nozzle ends, holding 40 to 80 grams. The paraffin used should be semi-solid, odourless, and tasteless, melting point 45° C., free from acidity and carbonizable organic impurities. The iodoform should be free from moisture, acids, and fixed impurities. It is also necessary that the bismuth be chemically pure, free from arsenic, and care taken in sterilizing that the temperature does not rise too high, otherwise nitrous fumes will be evolved.

A paste made by this method is found to be fairly solid in consistency, shows no signs of separation or decomposition, and is perfectly sterile, as certified by Dr. Slade, bacteriologist to this infirmary.

Should a paste be required of a softer consistency the formula may be modified as follows:

Iodoform	440	grams
Bismuth subnitrate	220	"
Paraffin base	220	"
		M.S.A.			

Paraffin base:

Paraffin melting point 45° C.	19	parts
Paraffin liq., sp. gr. 880	40	"

Special tubes with keys, suitable for the above preparation, can be obtained from Whitelaw and Co., Saville Row, Newcastle-on-Tyne, and tubes ready charged with Bipp sterilized according to my method are obtainable from the Numol Company, 3, College Street, Newcastle-on-Tyne.

Though this method has been used chiefly for war wounds it is applicable, as Case II shows, in civilian cases. My colleague, Dr. Samuel Whyllis, tells me that the method has revolutionized mastoid surgery, and I have a report from a London throat and ear surgeon telling me how much benefit had followed its use in his work—in mastoid cases.

Summary of Technique.

1. Under an anaesthetic, usually open ether, cover the wound with gauze wrung out of 1 to 20 carbolic acid, and clean the skin and the surrounding area with the same lotion.

2. Open the wound freely and, if possible, sufficiently to permit of inspection of its cavity. A guide—a finger is the best if the size of the wound permits of it, and if not a thick probe—should be introduced to the bottom of the wound and held there and fully exposed. In doing this special regard must be paid to nerve trunks and muscular branches of nerves, since the division of blood vessels, excepting the largest, and of muscles themselves does little harm as compared with that of the disability following nerve damage. Cleanse the cavity with dry sterile gauze mops, Volkmann's spoon, etc., and remove all foreign bodies.

3. Mop the surrounding skin and the wound cavity with methylated spirit and dry it.

4. Fill up the whole wound with Bipp, rub it well in with dry gauze. Then remove all excess, leaving only a thin covering over the wounded surface. Dress the wound with sterile gauze and cover all with an absorbent pad, which is held in position by sticking plaster and a bandage. This dressing requires no change for days or weeks if the patient is free from pain and constitutional disturbance. Should, however, discharge come through, the stained part must be soaked in spirit and a gauze dressing wrung out of the same applied as a further covering.

Redressing is very simply done. After removal of the old dressings the wound is covered with a dossil of wool soaked in spirit, and the sticky dirty-looking discharge is wiped off the surrounding skin until it is clean.

I am indebted to Colonel Adams for leave to publish the military cases.

DR. WARDELL STILES of the United States Public Health Service urges careful examination of all recruits of the National Guard and National Army, especially from the south, for hookworm. The parasite was found in forty-seven among seventy-five recruits. Dr. Stiles calls attention to the great danger of carrying the infection from America to Europe.

REPORT ON WOUND TREATMENT BY BRILLIANT GREEN PASTE.

BY

CAPTAIN A. RENDLE SHORT, M.D., B.S., B.Sc.,
F.R.C.S., R.A.M.C.(T.F.).

SENIOR ASSISTANT SURGEON, BRISTOL ROYAL INFIRMARY;

CAPTAIN J. S. ARKLE, M.B., B.S., R.A.M.C.(T.C.),

AND

CAPTAIN C. KING, M.B., B.C., R.A.M.C.(T.C.).

It has been abundantly proved by experience that to secure efficient sterilization of an infected wound it is necessary to apply antiseptic remedies, not occasionally, but continuously. There are two means of obtaining this end. The one is the use of the Carrel method of frequent introduction of fluids through rubber tubes, and the other is the thorough application of a paste to every hole and corner of the wound, as exemplified by the popular bipp of Rutherford Morison. Both these methods have drawbacks. The Carrel technique needs much attention, and when the patient is travelling this may not always be secured. The soaked dressings need daily changing. The tubes are liable to come out and it may need an anaesthetic to replace them. In "strafe" times it may be frankly impossible to devote sufficient time to carry it out.

Bipp is much less trouble, but presents drawbacks of another sort. It is occasionally poisonous, either from the bismuth or the iodoform, or both. It may delay healing; when the stitches are taken out after secondary suture the wound may fly open. It leaves a residue in the tissues, opaque to the x rays, which may give rise to trouble later. One of us has seen an unnecessary operation in England to remove iodoform from a hole in a tibia, suggesting in the skiagram a metallic fragment; and on another occasion, in civil practice, iodoform put into a tuberculous os calcis two years before was mistaken for a sequestrum.

We have therefore been employing for some months the paste introduced by Captain Hey, after long research into many methods, consisting of brilliant green, boric acid, French chalk, and liquid paraffin. It presents the following advantages:

1. It is non-poisonous. The symptoms of boric acid poisoning—persistent vomiting and a peculiar rash—should be watched for, but although in many cases we have used very large quantities of the paste we have seen no ill effect result from its use.

2. It is painless.

3. In the great majority of cases it almost completely sterilizes the wound in three days, so that secondary suture can be performed even in large wounds complicated by bony injury. Small, completely excised wounds can be primarily sutured.

4. The wound need only be dressed about once in four days.

5. No permanent residue is left to interfere with immediate healing.

Before applying the paste the wound must be thoroughly opened up and excised, and any foreign bodies removed. If this is not possible—for example, in a shocked patient with multiple wounds or with a long deep track exposing important structures—we prefer to use Carrel's method. The paste is only to be applied if it can be applied completely. The wound ought to be dry and not bleeding, but a certain amount of oozing can be checked by a gauze plug (preferably paraffin gauze, which is easier to remove). The paste should be rubbed in thoroughly. It soon washes off the skin or gloves.

By this method we have been able with fair consistency to obtain healing within a fortnight of cases of compound fracture even when complicated by joint injury, big buttock wounds and deep muscle wounds. We have excised an elbow-joint full of pus, and obtained primary healing in a fortnight.

The usual procedure is to stain the track of the missile, excise and paste it, and either leave it open or insert a few central sutures. On the third or fourth day a smear of the deepest part of the wound is taken. If *B. perforans* is absent, as is almost invariably the case, and the organisms are not more than six to the field, we completely close the wound by secondary suture. Often the

wound shows no organisms at all. It is easier to count the organisms with this method than when bipp has been used. A little redness and swelling on the fourth day can usually be remedied completely by hot fomentations.

We find that Hey's method of staining the wound by injecting through a Carrel's tube with a 1 in 200 watery solution of brilliant green is a very valuable aid to complete excision.

In ten cases it will be observed that the method has failed of complete success. Of these, four (Cases 10, 17, 23, and 33) were hopeless from the beginning. One of them (Case 23) was an attempt to save a leg in which it was afterwards found that both tibial arteries were divided in addition to the presence of a big muscular wound and a smashed tibia and fibula. The excision was inadequate owing to shock and consequent hurry, and it became necessary to amputate for gas gangrene. In another (Case 10), in which death followed within forty-eight hours from gas gangrene, the bad condition of the patient did not permit of a prolonged search for the foreign body. The appearance of the wound at the time of operation suggested early gas gangrene, which had already spread too far for complete excision. The other two (Cases 17 and 33) are sufficiently described in the notes. In Case 43 the use of the paste resulted in clean healing wounds, death being due to other causes. In two other cases (8 and 9) proper excision of the wound was impossible and both suppurated. The other three cases of this group (28, 29, 30) were large deep wounds, which did well for four or five days and then suppurated. Probably the original pasting is not effective after three days. These cases could have been kept clean by repasting under an anaesthetic.

Just now we are trying a flavine paste. Sufficient material is not yet available for a report. The results are so far very similar to those obtained with brilliant green.

The undermentioned series of cases is classified under three headings:

Class I: Remarkably successful, in that the wounds were very extensive and in general were complicated by bone or joint injury.

Class II: Less serious cases giving perfectly satisfactory results.

Class III: Relatively unsuccessful.

The report includes every case up to August 16th in which the paste was used. In all cases the wounds were stained, excised, and the foreign body removed on the day of admission. Any deviation from this procedure is recorded in the notes of cases.

SUMMARY OF CASES.

CLASS I.—Remarkably Successful.

Case 1.—Pte. F. D.; admitted July 8th, 1917, with the following shell wounds: (1) Penetrating wound of left knee; (2) gutter wound of right leg, grazing patella; (3) multiple wounds of left thigh; (4) multiple wounds of arm, one penetrating elbow. Usual treatment, except thigh and arm, where wounds could only be partially excised.

July 13th. Secondary suture of wound of right leg.

July 20th. Elbow septic, other wounds clean. On July 25th the elbow was drained, and on August 2nd the elbow-joint formally excised for suppurative arthritis; paste was applied and the wound closed by primary suture with drainage. The drain was removed on August 6th, and on the 12th the elbow wound was healed by first intention, there was no febrile reaction, the other wounds were firmly healed, and the patient was evacuated to the base.

Case 7.—Pte. H. T.; admitted July 11th, 1917, with shell wounds of leg (with compound comminuted fracture of tibia), thigh, and back.

July 18th. Leg wound repasted and sutured.

July 25th. Healing; slight serous discharge from tibia; no pus; other wounds satisfactory. Evacuated to base.

Case 15.—Pte. C.; admitted July 13th, 1917, with shell wound of knee. Operation twenty-four hours after injury; thigh swollen and inflamed; foreign body removed from popliteal surface of femur.

July 19th. Repasted and sutured, except small space in centre of wound.

July 25th. Healing; wound clean. Evacuated to base.

Case 16.—Pte. R. G.; admitted July 14th, 1917, with shell wound of buttock with divided gluteal artery. Repasted at intervals without anaesthetic.

July 25th. Skin edges freshened and sutured; glove drain. Drain removed two days later; wound clean.

July 30th. Healing. Evacuated to base. Report from base: One stitch removed on arrival; rest of wound healed.

Case 31.—Pte. A. D.; admitted July 24th, 1917. Shell wound of forearm with compound fracture of radius. Primary suture. On the 30th the wound was healing, and the patient was evacuated to the base.

Case 32.—Pte. R. C.; admitted July 24th, 1917. Shell wound of leg with compound fracture of tibia. Repasted and sutured on the 27th. Three days later the wound was healing, and the patient was evacuated to the base.

August 3rd. Report from base: Wound healed.

Case 34.—Pte. B. C.; admitted July 27th, 1917. Trench mortar wounds of neck, exposing vertebrae, and ankle, with compound fracture of tibia and division of posterior tibial vessels and nerve.

July 31st. Secondary suture of neck; ankle wound repasted. Loss of skin too extensive for suture. Patient evacuated to the base a few days later with both wounds clean.

Case 35.—Pte. J. M.; admitted July 28th, 1917. Shell wound of arm with compound fracture of humerus and divided brachial artery. Secondary suture was performed on August 2nd; the stitches were removed on the 10th, when the wound was healed. Two days later he was evacuated to the base.

Case 39.—Pte. W. C.; admitted July 29th, 1917. Bomb wound of knee (penetrating) with compound fracture of patella, and superficial wound of chest wall. Patella sewn with catgut; partial primary suture.

August 11th. Both wounds healed; no rise of temperature; joint never swollen. Evacuated to base.

Case 40.—Pte. A. B.; admitted July 30th, 1917. Shell wound of arm with compound comminuted fracture of radius and ulna. On August 3rd the outer wound was completely sutured; the inner wound as far as skin available.

August 12th. Outer wound healed and dry; inner wound clean, no pus. Evacuated to base.

Case 47.—Pte. R. W.; admitted July 31st, 1917, with bomb wounds of buttock and thigh; buttock wound deep, 7 in. track. Secondary suture was performed on August 3rd. On the 12th the wounds were healed, there was no suppuration, and the patient was evacuated to the base.

Case 48.—Lce.-Cpl. A. C.; admitted July 31st, 1917, with bomb wound of thigh; track 17 in. long through muscles; patient very collapsed on admission.

August 4th. Lower half of wound sutured, remainder repasted. Two days later there was slight purulent discharge from the upper end of the wound; second foreign body localized by x rays and removed; wound repasted.

August 10th. Remainder of wound sutured.

August 14th. Wound healed.

Case 49.—Pte. G. G.; admitted August 2nd, 1917. Bullet wound of forearm with compound fracture of radius. Primary suture. On August 7th the wound was doing well; there was no suppuration. On the 12th it was healed, and the patient was evacuated to the base.

Case 57.—Cpl. W. L.; admitted August 7th, 1917. Shell wound of forearm with compound fracture of radius; much loss of blood prior to admission. On August 10th the wound was repasted and sutured; on the 16th it was clean and healing, and the patient was evacuated to the base.

Case 61.—Pte. A. S.; admitted August 9th, 1917. Shell wounds of both forearms, with compound fractures of right ulna and left radius. On August 12th both wounds were sutured. On the 16th they were clean and healing, and the patient was evacuated to the base.

Case 62.—Pte. J. R.; admitted August 9th, 1917. Accidental injury: compound fracture of tibia and fibula. On August 15th the wound was perfectly clean.

CLASS II.—Successful.

Case 2.—Pte. E. H.; admitted July 8th, 1917. Shrapnel wounds (penetrating) of knee, with fracture, and of thigh (missile embedded in femur). Patient too collapsed for operation on admission. On recovery, amputation of left thigh (lower third); the right thigh treated by other method as control. On July 17th the wounds were repasted and amputation flaps sutured.

July 25th. Healing; no discharge. Evacuated to base. Report from base: Sutures removed; wound healed; slight suppuration from right thigh (control).

Case 3.—Pte. T. G.; admitted July 10th, 1917. Bullet wound of leg with division of peroneal vessels. On July 13th secondary suture was performed; on the 18th the sutures were removed, when there was partial gaping of a clean wound. On the 25th he was evacuated to the base with the wound clean.

Case 4.—Pte. H. L.; admitted July 10th, 1917. Shell wound of leg, with compound comminuted fracture of tibia and fibula and division of popliteal artery. Very collapsed on admission. Supracondylar amputation; flaps loosely sutured.

July 12th. Slight reactionary haemorrhage; clot turned out and wound repasted. This was followed by slight purulent discharge for a few days.

July 20th. Edges of flap freshened and sutured with drainage. Drain removed two days later.

July 30th. Evacuated to base; wound healing.

Case 5.—Pte. H. G.; admitted July 11th, 1917, with extensive gutter wound of thigh through muscles. On July 18th the

skin was approximated by sutures, but the wound could not be completely closed owing to loss of tissue.

July 22nd. Evacuated to base. Wound clean.

Case 6.—Cpl. W. O.; admitted July 11th, 1917, with shell wound of shoulder, superficial. On the 13th secondary suture was performed. He returned to duty on July 31st with a sound scar.

Case 11.—Pte. W. L.; admitted July 12th, 1917, with shell wound of back. Primary suture. Evacuated to base on July 22nd with the wound healed.

Case 12.—Pte. D. S.; admitted July 12th, 1917, with bullet wound of shoulder. On July 14th secondary suture was performed; on the 20th the wound was clean and healing, and the patient was evacuated to the base.

Case 13.—Pte. W. J.; admitted July 12th, 1917, with the following shell wounds: (1) Chest, opening pleura; (2) scapular region; (3) arm; (4) penetrating head (pasted and cleaned only). July 20th. All wounds clean; no suppuration; no head symptoms. Evacuated to base.

Case 14.—Spr. C. B.; admitted July 13th, 1917. Shell wound of back of thigh twenty-four hours before admission. Femur exposed but not fractured. Wound repasted and sutured on July 18th. Patient evacuated to base on July 25th, wound healing.

Case 18.—Pte. A. W.; admitted July 15th, 1917, with shell wounds of both legs. On July 21st secondary suture was performed, and on the 27th the wounds were healing, and the patient was evacuated to the base.

Case 19.—Pte. H. R.; admitted July 15th, 1917, with shell wound of back. Secondary suture was performed on July 19th, and three days later the patient was evacuated to the base with the wound healing.

Case 20.—Lce.-Cpl. M. W.; admitted July 15th, 1917, with shell wound of leg. Primary suture. On July 22nd the wound was healing, and patient was evacuated to the base.

Case 21.—Pte. O. M.; admitted July 15th, 1917, with shell wound of buttock. Secondary suture on July 21st. On the 25th wound healing, and patient evacuated to the base.

Case 22.—Pte. W. L.; admitted July 18th, 1917, with shell wounds of arm and both legs and thigh. On July 22nd the wounds were clean and closed with strapping. Patient evacuated to base on August 1st with the wounds healing.

Case 24.—Pte. C. G.; admitted July 18th, 1917, with shell wound of buttock. Two days later the wound was clean and patient was evacuated to the base.

Case 25.—Pte. J. H.; admitted July 19th, 1917. Shell wound of thigh and hand with compound fracture of metacarpals. Patient evacuated to base on August 1st with the wounds clean.

Case 26.—Pte. J. C.; admitted July 20th, 1917, with shell wound of leg. On the 25th the wounds were clean, and patient was evacuated to the base.

Case 27.—Pte. P. S.; admitted July 21st, 1917, with shell wound of buttock. Foreign body not removed. Patient evacuated to base on August 30th with the wound clean.

Case 36.—Lieut. E. G. E.; admitted July 28th, 1917. Bomb wounds of both legs, with gas gangrene of right. Very collapsed on admission. Direct blood transfusion. Flush amputation through right knee-joint.

August 1st. Amputation redressed under gas; wounds clean. Evacuated to base three days later with the wounds still clean.

Case 37.—Pte. J. V.; admitted July 28th, 1917, with shell wound of left arm. On the following day blood clot turned out and wound repasted. Secondary suture performed on August 3rd. Patient evacuated to base on August 12th with the wound healing.

Case 38.—Pte. H. B.; admitted July 29th, 1917. Shell wound of face with compound fracture of maxilla. Evacuated to base on August 1st; wounds clean.

Case 41.—Pte. C. B.; admitted July 30th, 1917, with shell wound of leg, exposing bone. Secondary suture on August 1st. Wound healed on August 12th, and patient evacuated to base.

Case 42.—Pte. G. D.; admitted July 30th, 1917, with shell wound of back. Primary suture. Stitches removed on August 7th; wound healed. Evacuated to base on August 12th; satisfactory.

Case 44.—Pte. G. P.; admitted July 31st, 1917. Old shell wound of thigh, with persistent sinus. Foreign body removed from side of femur by counter-incision; sinus excised. Secondary suture on August 2nd. On August 12th the patient was evacuated to the base with the wound healed.

Case 45.—Pte. F. D.; admitted July 31st, 1917, with shell wounds of arm and thigh. Primary suture of thigh. Secondary suture of arm on August 2nd. Stitches removed from thigh on August 7th; wound dry and healed. Evacuated to base on August 12th with both wounds healed.

Case 46.—Pte. J. F.; admitted July 31st, 1917. Shell wound in occipital region, with damage to bones. Primary suture. Stitches removed on August 12th; wound healed; patient evacuated to base.

Case 50.—Pte. P. J.; admitted August 2nd, 1917. Shell wound of hand, with compound fracture of metacarpal. Available tissue sutured two days later. Patient evacuated to base on August 12th with the wound clean.

Case 51.—Pte. P. C.; admitted August 3rd, 1917, with shell wound of buttock. Primary suture. The wound was healed on August 15th, and patient was evacuated to the base.

Case 52.—Lce.-Cpl. R. O.; admitted August 5th, 1917, with trench mortar wounds of forehead and arm. Primary suture of both wounds.

August 11th. Sutures removed from head; wound healed. Arm healing. Evacuated to base.

Case 53.—Pte. J. H.; admitted August 5th, 1917, with shell wound of head penetrating brain. Primary suture.

August 16th. Stitches removed; wound healed. Still in hospital, awaiting train.

Case 54.—Lce.-Cpl. S. A.; admitted August 6th, 1917, with shell wounds of back and leg. Secondary suture four days later. On August 16th wounds clean; awaiting train.

Case 55.—Lce.-Cpl. E. D.; admitted August 6th, 1917, with shell wound of scalp. Primary suture. Patient evacuated to base on August 12th with the wound healed.

Case 56.—Dvr. H. T.; admitted August 7th, 1917, with shell wound of shoulder. Long track only partially excised owing to exposure of brachial plexus. Patient evacuated to base on August 12th with the wound clean.

Case 58.—Pte. J. G.; admitted August 8th, 1917, with shell wounds of shoulder and leg. Primary suture of leg. Secondary suture of shoulder three days later. On August 16th both wounds were clean and healing; patient awaiting train.

Case 59.—Dvr. M. M.; admitted August 8th, 1917, with shell wound of head. Primary suture. Patient evacuated to base on August 12th with the wound healing.

Case 60.—Pte. W. T.; admitted August 9th, 1917, with shell wound of chest wall. Primary suture.

August 16th. Healing. Awaiting train.

Case 63.—Pte. H. S.; admitted August 10th, 1917, with shell wound of thigh. Sutures inserted but not tied. Sutures tied on August 11th. On the 16th the wound was healing and patient awaiting train.

Case 64.—Lce.-Cpl. L. F.; admitted August 10th, 1917, with shell wound of thigh. Primary suture. On August 16th the wound was dry and healing, and patient awaiting train.

CLASS III.—Relatively Unsuccessful.

Case 8.—Sgt. B.; admitted July 11th, 1917. Shell wound of back, with compound comminuted fracture of both scapulae. Very extensive wounds, excised as far as possible. Patient extremely ill for several days. Both wounds suppurated, but settled down under fomentations without any further operative interference.

July 30th. Evacuated to base. Wounds granulating.

Case 9.—Pte. J. K.; admitted July 12th, 1917, with the following shell wounds: (1) Heel—one foreign body removed from os calcis and one left embedded in bone; (2) leg—foreign body not found in calf muscles; (3) forearm—two compound fractures of ulna; wounds partially excised; (4) hand—one finger blown away; stump trimmed. The patient's condition was so serious that complete operation was impossible. Wounds suppurated with spreading sepsis in forearm.

July 17th. Further incisions in arm; leg required no interference.

July 30th. Condition settled; still some mild suppuration. Evacuated to base.

Case 10.—Pte. J. D.; admitted July 12th, 1917, with shell wounds of both buttocks, one involving the thigh. Foreign body retained in thigh. Wounds already stinking. Death took place two days later. The autopsy showed extensive gas gangrene.

Case 17.—Pte. J. W.; admitted July 14th, 1917, with extensive shell wound of thigh involving femur. Patient exsanguined. Death took place the same day, within twelve hours of operation. Patient never rallied and died from shock and haemorrhage. The autopsy showed no sepsis.

Case 23.—Lieut. H. L.; admitted July 17th, 1917. Shell wound of leg, with compound fracture of tibia and fibula; both sets of tibial vessels subsequently found to be divided. Patient shocked and exsanguined. Hurried operation.

July 18th. Gas gangrene in leg. Guillotine amputation at knee-joint; stump pasted.

July 25th. No further sepsis. Evacuated to base.

Case 28.—Pte. C. A.; admitted July 22nd, 1917, with bullet wound of the chest wall and arm, dividing ulnar nerve.

July 26th. Arm remained quite clean; chest suppurated. Temperature unaffected. Cleaned up in five days with Carrel-Dakin treatment.

August 1st. Wounds clean. Evacuated to base.

Case 29.—Pte. H. S., admitted July 23rd, 1917. Shell wound of chest, with compound fracture of scapula. Primary suture. Clean for four days, then slight purulent discharge. Stitches removed; Carrel-Dakin treatment.

August 2nd. Wound clean.

August 12th. Approximated with strapping. Evacuated to base.

Case 30.—Pte. F. M.; admitted July 24th, 1917. Large shell wound of leg, with compound fracture of tibia and division of posterior tibial vessels and nerve; extensive laceration of muscles. Amputation. Wound clean for four days, then profuse purulent discharge. Carrel-Dakin treatment.

August 7th. Clean but huge open wound. Patient evacuated to base on August 12th.

Case 33.—Pte. S. W.; admitted July 25th, 1917. Shell wound of thigh, with compound fracture of femur and whole of back of thigh blown away. Extreme shock, contraindicating general anaesthetic other than nitrous oxide. No excision of wound; only pasting. The following day the wound was stinking, and the patient's condition prevented operative treatment.

July 29th. Death from shock and sepsis.

Case 43.—Pte. W. G.; admitted July 30th, 1917, with the following shell wounds: (1) Back, with fractured spine and paralysis of bladder; (2) head, penetrating brain. Primary suture of head.

August 7th. Wounds clean.

August 12th. Head wound healed; back wound clean. Pyuria.

August 16th. Death. Autopsy showed sepsis of whole urinary track. Wounds clean.

THE USE OF LIQUID PARAFFIN IN THE TREATMENT OF WAR WOUNDS.

BY

TEMPORARY COLONEL H. M. W. GRAY, C.B., A.M.S.,

CONSULTANT SURGEON.

DURING the past year much clinical observation has been carried out in several Casualty Clearing Stations in this Army on the effect of liquid paraffin upon wounds at different stages.

The results of these observations enable one to state:

1. That liquid paraffin has, almost without exception, a very beneficial action on the walls of a wound and on the tissues adjacent to the wound. It prevents development of the symptoms of inflammation in these parts and will cause such symptoms to disappear rapidly if they are already present. The skin remains or becomes normal in appearance; redness and swelling do not develop or, if present, disappear. Pain is assuaged. Performance of function becomes easier, although, of course, this is frequently restrained by therapeutic agencies and is therefore not evident. Changes of dressings are comparatively painless.

One does not care at this stage to discuss possible explanations of these effects of the paraffin, but it may be pointed out that the "electrical" conditions of wounds have usually hitherto been entirely disregarded, only chemical and mechanical conditions having been considered. Electrical conditions of wounds, as revealed by the galvanometer, are found to vary, in a very consistent way, with the age of the wound and the amount of inflammation present.

2. Liquid paraffin is not antiseptic in the ordinary sense of the term. If a wound be "packed" with gauze wrung loosely out of the paraffin, it is found that in two to four days the discharge in the wound swarms with organisms, although the surrounding parts are free from inflammation. The "wound" with the fluid part of its contents may be likened to a test tube containing nutritive medium in which organisms are thriving. In either case the addition of antiseptic will lessen or entirely inhibit the growth. If an antiseptic is dissolved or suspended in the liquid paraffin with which the gauze pack is saturated, it is found that the wound remains or becomes sterile. Various antiseptics or mixtures of antiseptics have been used, with good effects in all cases, although these effects vary, possibly owing to selective effect of the particular antiseptic against the particular organism or to tolerance acquired by the organisms for the antiseptic employed against them. Those chiefly used up to the present are flavine, brilliant green, boric acid, and iodoform. It is rather difficult to justify preference for any one. A combination seems desirable. Non-poisonous antiseptics with more or less prolonged action when in contact with body fluids are likely to be most successful. It seems that, although the effects of micro-organisms on the tissues adjacent to a wound are inhibited, absorption of chemical antiseptics from the wound may occur and cause symptoms of poisoning.

One would desire to draw attention to papers sent for publication by Captain W. H. Hey and others (p. 506),

which deal with clinical results obtained from the use of pastes made with liquid paraffin as a base. Captain Hey found that pastes made with other substances—for example, gums—are inferior in curative action to those made with paraffin. During his investigations Captain Hey did not regard the bases with which his various pastes were made up as being anything else than "neutral."

It has been stated that the paraffin in bipp paste delays healing. Delay in healing of recent wounds, as has been observed in "bipped" cases, has not occurred in paraffin pastes made up with antiseptics soluble in serum. It seems more likely that the excess of bismuth subnitrate and iodoform in bipp is responsible by preventing adhesion of apposed surfaces.

The only type of inflammation, in cases which are not already too far advanced to recover, which in my experience has not yielded to the free application of liquid paraffin is that exemplified in a wounded limb which becomes much swollen, brawny, grossly nodular, and brownish-red, the wound being covered with granulations which look like dirty pale pink frog's spawn.

In all cases it is essential for success to have thorough preliminary opening up and mechanical cleansing of the wound. A piece of half-dead muscle left behind, infected with gas bacilli, is not likely to become disinfected by antiseptics, especially when the patient's resisting powers are at a low ebb; the paraffin is likewise at a disadvantage because the affected tissues cannot react in the ordinary way. Gauze used for packing a wound smeared with a paraffin paste should be wrung out of liquid paraffin or iodoform-paraffin (1 per cent.), and the skin around the wound covered with similarly impregnated gauze. Captain Hey, Captain Short, Captain J. Anderson, and others have shown that wounds may be sutured with success at a very early stage after treatment by such methods.

REINFECTION IN SYPHILIS;

WITH OBSERVATIONS ON 23 CASES.

BY

CHARLES F. WHITE, MAJOR R.A.M.C.

PROBABLY, though it would be a question difficult to settle, there is no such thing as a natural immunity from syphilis. However this may be, it was held until recently that immunity from syphilis might be acquired. The older theory, now abandoned, was that one infection of syphilis produced immunity from further infection; in other words, that syphilis could be acquired once only in a lifetime. Careful investigation appears to establish—

1. That reinfection can take place.
2. That such reinfection cannot take place until the original infection has been completely cured.

With the older treatment of syphilis a complete cure was difficult, or very rare, and consequently cases of reinfection were so exceptional that a doubt of their existence was not unreasonable.

The collection and examination of instances of reinfection are therefore of great importance. First, as showing beyond doubt that reinfection is a fact, and, secondly, as amounting to almost complete proof of the cure of the first attack.

Since the introduction of the combined salvarsan and mercury treatment for syphilis the number of cases of genuine reinfections reported has increased—a sure sign of the curative efficacy of this treatment and a proof that one attack of syphilis does not produce immunity. Perhaps we should not be far wrong in saying that the only persons immune from syphilis are the syphilitics.

Formerly proof of reinfection was based on clinical evidence alone and was open to certain fallacies, namely:

(a) *In the Case of the First Attack.*—Absence of positive proof of syphilis in those cases in which treatment was started in the primary stage and in which secondary symptoms did not develop. As no microscopic examination was made, or in the failure to find spirochaetes in serum from the sore, it was always possible that the diagnosis was mistaken. In other words, there was no positive proof that the chancre was syphilitic and not a soft sore.

(b) *In the Case of the Second Attack.*—(1) A soft chancre, (2) a recurrent chancre, (3) a chancriform gumma, or

(4) a pseudo-chancere (that is, a mucous genital syphilide which may have undergone induration), being mistaken for primary syphilitic chancres, or (5) the recurrent rashes being perhaps put down as fresh secondary syphilides and regarded as proof of a second attack.

Since the discovery by Schaudinn and Hoffmann of the *Spirochaeta pallida* as the cause of syphilis and the introduction of the Wassermann serum test as an aid to its diagnosis and cure, positive proof of reinfection can in certain cases be given apart from the clinical evidence.

We may lay down the following conditions:

1. In the first attack, *Spirochaeta pallida* being found from the chancere or syphilitic lesions (condyloma, mucous patch, or rash) or the blood giving a positive Wassermann reaction (here we must exclude the positive Wassermann of cases of hereditary syphilis); and

2. In the second attack, *Spirochaeta pallida* being found from the new chancere which appeared at a different site from the first chancere, and the blood at the same time giving a negative Wassermann reaction, which of course implies that the patient must have been seen shortly after the appearance of the second chancere, or at least before the blood had had time to become positive.

If we can produce cases to fulfil the above conditions, we have very strong confirmatory evidence apart from our clinical observation and opinion that reinfection has actually taken place.

The following list of cases of reinfection (Series I), which were all seen and treated by me during both attacks, fulfil the above conditions. The notes given are in each case those taken down at the time of the patient's first and second admission to hospital.

SERIES I.

CASE I.

First Admission (December 1st, 1915).—The patient was admitted to hospital with (1) a primary papular erosive syphilitic sore at the fraenum, (2) adenitis in both groins. There was no other visible sign of syphilis. The period of incubation was three weeks. *Spirochaeta pallida* was present on dark-ground examination. He was treated with eight injections of 0.3 gram of salvarsan and seven weekly injections of 1 grain mercury cream. Treatment was completed on February 22nd, 1916.

Second Admission (August 12th, 1916).—The patient was admitted to hospital a second time with (1) a primary granulating syphilitic sore on the anterior aspect of skin of foreskin, (2) glands in groins enlarged and shot-like. The incubation period was four weeks. *Spirochaeta pallida* was present on dark-ground examination. The Wassermann reaction was negative both before and after treatment. Treatment was the same as on his first admission, and was completed on October 3rd, 1916.

CASE II.

First Admission (August 24th, 1915).—Signs of infection: (1) Primary papular syphilitic sore on inner surface of prepuce; (2) shotty glands in both groins. No other visible sign. Incubation period uncertain. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream. Treatment was completed on October 26th, 1915.

Second Admission (June 14th, 1916).—Signs of infection: (1) Typical papular erosive primary syphilitic sore on dorsal surface of prepuce; (2) shotty glands in both groins. No other visible sign. The incubation period was again uncertain. *S. pallida* present on dark-ground examination. Wassermann test negative. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and five weekly injections of 1 grain mercury cream. Treatment completed August 26th, 1916.

CASE III.

First Admission (July 16th, 1915).—Signs of infection: (1) Typical meatal syphilitic chancere; (2) glands in both groins painlessly enlarged and swollen. No other visible sign. Incubation period four weeks. On dark-ground examination *S. pallida* was seen to be present. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream. Treatment completed August 22nd, 1915.

Second Admission (June 21st, 1916).—Signs of infection: (1) Typical Hunterian chancere in left side of coronal sulcus; (2) glands in both groins slightly enlarged and hard. No other visible sign. Incubation period uncertain; sore noticed five days. *S. pallida* present on dark-ground examination. Wassermann test negative. Treatment: Three injections of 0.3 gram salvarsan and two weekly injections of mercury cream. The patient was transferred to another hospital for completion of treatment.

CASE IV.

First Admission (April 21st, 1915).—Signs of infection: (1) Large scar of primary, probably granulating, syphilitic sore on dorsum of body of penis; (2) condylomata on scrotum; (3) general adenitis. No other visible sign. Incubation period uncertain. Wassermann test positive. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream. Treatment completed May 24th, 1915.

Second Admission (October 22nd, 1915).—Signs of infection: (1) Partly healed papular erosive primary syphilitic sore on outside of prepuce; (2) scar of former sore on body of penis; (3) adenitis in both groins. Incubation period uncertain. On October 26th Wassermann test negative, Stern incomplete; November 4th, Wassermann negative, Stern positive; December 15th, Wassermann positive, Stern positive. Treatment: Eight injections of 0.3 gram salvarsan and seven weekly injections of 1 grain mercury cream. Treatment completed February 5th, 1916.

CASE V.

First Admission (October 1st, 1915).—Signs of infection: (1) Typical Hunterian chancere on inner surface of prepuce; (2) enlarged and shot-like glands in both groins. No other visible sign. Incubation period uncertain; patient first noticed sore five days before. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream. Treatment completed November 2nd, 1915.

Second Admission (March 28th, 1916).—Signs of infection: (1) Typical primary granulating syphilitic sore on outside of foreskin; (2) glands in groins hard and enlarged. No other visible sign. Incubation period four weeks. *S. pallida* present on dark-ground examination. Wassermann and Stern tests negative. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and six weekly injections of 1 grain mercury cream. Treatment completed May 11th, 1916.

CASE VI.

First Admission (September 6th, 1915).—Signs of infection: (1) Sloughing primary papular syphilitic sore on end of prepuce; (2) glands in both groins hard and enlarged. No other visible sign. Incubation period five weeks; noticed sore seventeen days after exposure. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream. Treatment completed October 12th, 1915.

Second Admission (March 24th, 1916).—Signs of infection: (1) Hard sore beneath prepuce—unable to completely retract foreskin; (2) glands in groin slightly enlarged. No other visible sign. Last exposure to infection two months before; noticed sore two weeks before admission. *S. pallida* present on dark-ground examination. Wassermann reaction negative. Treatment same as on first admission; completed May 9th, 1916.

CASE VII.

First Admission (October 10th, 1915).—Signs of infection: (1) Balanitis with indurated sore beneath prepuce; (2) shotty glands in groin and neck. No other visible sign. Incubation period uncertain; noticed sore two weeks before admission. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream; completed November 11th, 1915.

Second Admission (September 5th, 1916).—Signs of infection: (1) Two typical primary papular erosive syphilitic sores on right side of coronal sulcus; (2) adenitis in groins. No other visible sign. Last exposure to infection six weeks before. *S. pallida* present on dark-ground examination. Wassermann reaction negative. Treatment: Three injections of 0.3 gram salvarsan and two weekly injections of 1 grain mercury cream. Transferred to another hospital for completion of treatment October 12th, 1916.

CASE VIII.

First Admission (August 6th, 1915).—Signs of infection: (1) Indurated papular erosive sore on inner surface of prepuce; (2) commencing roseolar rash on chest and abdomen; (3) general adenitis. No other visible sign. Incubation period four weeks. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and seven weekly injections of 1 grain mercury cream. Treatment completed September 21st, 1915, when the Wassermann reaction was negative.

Second Admission (September 26th, 1916).—Signs of infection: (1) Typical primary papular erosive syphilitic sore on inner surface of prepuce close to left of fraenum; (2) small abrasions on inner surface of prepuce on left side close to corona; (3) general adenitis. No other visible sign. Incubation period about four weeks. *S. pallida* present on dark-ground examination. Wassermann reaction negative. Treatment: Four injections of 0.3 gram salvarsan and two weekly injections of 1 grain mercury cream. Transferred to another hospital for completion of treatment October 21st, 1916.

CASE IX.

First Admission (June 29th, 1915).—Signs of infection: (1) Primary papular ulcerative syphilitic sore at fraenum, non-inflammatory syphilitic oedema of prepuce; (2) glands in both groins hard and enlarged. No other visible sign. Incubation period uncertain. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream. Treatment completed July 31st, 1915.

Second Admission (May 16th, 1916).—Signs of infection: (1) Two fairly typical small primary syphilitic sores on inner surface of prepuce; (2) glands in groins hard and enlarged. No other visible sign. Last exposure to infection took place six weeks before. *S. pallida* present on dark-ground examination. Wassermann test negative. Treatment: Five injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream. Transferred to another hospital for completion of treatment June 26th, 1916.

CASE X.

First Admission (December 1st, 1915).—Signs of infection: (1) Primary indurated papular erosive syphilitic sore at fraenum; (2) bubo in left groin and shotty adenitis in right groin. No other visible sign. Incubation period unreliable. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream; completed January 25th, 1916.

Second Admission (July 21st, 1916).—Signs of infection: (1) Typical Hunterian chancre on inner surface of prepuce extending into coronal sulcus; (2) shot-like glands in both groins. No other visible sign. Incubation period not reliable. *S. pallida* present on dark-ground examination. Wassermann test negative. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and four weekly injections of 1 grain mercury cream; completed September 7th, 1916.

On the other hand there are cases of probably genuine reinfection that cannot fulfil the above conditions; for example, the conditions mentioned might be fulfilled with the exception that the patient was not seen in his second attack until the Wassermann reaction had become positive, or until secondary symptoms had appeared; such a case would then be open to the objection that it was really an instance of relapse, and not of reinfection.

In such a case the correctness of the diagnosis depends on the accuracy of the observation and the extent of the special experience of the practitioner, but anyone who has had considerable experience of syphilis must be fairly confident that he has seen genuine cases of reinfection, though the stringent conditions of "Series I" were not fulfilled.

In Series II will be found a record of such cases.

SERIES II.

CASE I.

First Admission (April 23rd, 1915).—Signs of infection: Small papular erosive syphilitic sore at fraenum. No other visible sign. Incubation period two weeks. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream. Treatment completed May 22nd, 1915.

Second Admission (August 29th, 1915).—Signs of infection: (1) Typical Hunterian chancre on inner surface of prepuce; (2) glands in groins a little enlarged. No other visible sign. Incubation period uncertain; sore noticed six days before admission. Wassermann test negative. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream. Treatment completed October 12th, 1915.

CASE II.

First Admission (May 28th, 1915).—Signs of infection: Indurated papular ulcerative syphilitic sore in coronal sulcus. No other visible sign. Sore noticed six days before admission. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and seven weekly injections of 1 grain mercury cream. Treatment completed June 29th, 1915.

Second Admission (September 10th, 1915).—Signs of infection: Non-inflammatory syphilitic oedema of prepuce with indurated lump to be felt beneath phimosed prepuce. Sore noticed for six weeks. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream. Treatment completed October 13th, 1915.

CASE III.

First Admission (June 9th, 1915).—Signs of infection: (1) Typical primary papular erosive syphilitic sore on inner surface of prepuce; (2) shotty glands in groins. No other visible sign. Incubation period two weeks. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream. Treatment completed July 20th, 1915.

Second Admission (July 22nd, 1916).—Signs of infection: (1) Primary granulating syphilitic sore on dorsum of body of penis; (2) glands in groin enlarged and shot-like. No other visible sign. Incubation period uncertain; sore noticed for five weeks. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and seven weekly injections of 1 grain mercury cream. Treatment completed September 7th, 1916.

CASE IV.

First Admission (September 9th, 1915).—Signs of infection: (1) Typical Hunterian chancre on inner surface of prepuce; (2) shotty glands in groins and neck. No other visible sign. Noticed sore eight days before admission. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream; completed October 12th, 1915.

Second Admission (February 7th, 1916).—Signs of infection: (1) Typical papular erosive syphilitic sore near fraenum; (2) adenitis in groins. No other visible sign. The sore is distinct from scar of original sore. Incubation period two weeks. *S. pallida* present on dark-ground examination. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and seven weekly injections of 1 grain mercury cream; completed March 20th, 1916.

CASE V.

First Admission (April 26th, 1916).—Signs of infection: (1) Typical primary papular erosive syphilitic sore in middle line of upper lip; (2) marked swelling of submaxillary glands and general adenitis; (3) macular papular rash covering body and limbs; (4) condylomata on scrotum. Denies all exposure to infection. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and seven weekly injections of 1 grain mercury cream; completed June 13th, 1916.

Second Admission (July 24th, 1916).—Signs of infection: (1) Balanitis with a typical Hunterian chancre in coronal sulcus of penis; (2) glands in both groins enlarged and hard. No other visible sign. Incubation period uncertain. Wassermann test negative. Treatment: Five injections of 0.3 gram salvarsan and four weekly injections of 1 grain mercury cream. Transferred to another hospital for completion of treatment August 27th, 1916.

CASE VI.

First Admission (October 30th, 1915).—Signs of infection: (1) Primary papular erosive syphilitic sore on under surface of prepuce; (2) glands in groins hard and enlarged; (3) papular roseolar syphilide on body and limbs and also on face; (4) mucous patches on tonsils; (5) headaches. Incubation period uncertain; sore seen four weeks and rash ten days before admission. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream; completed December 7th, 1915.

Second Admission (June 3rd, 1916).—Signs of infection: (1) Typical primary papular erosive chancre on lower lip just to left of middle line; (2) enlargement and hardness of submaxillary glands on left side. No other visible sign. Old scar of previous sore present under surface of prepuce. Most recent venereal exposure six weeks before admission. On dark-ground examination, *S. pallida* present from chancre on lip. Wassermann and Stern tests positive. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream; completed July 24th, 1916.

CASE VII.

First Admission (August 4th, 1915).—Signs of infection: (1) Three typical primary papular erosive syphilitic sores in coronal sulcus of penis; (2) shotty glands in groins. No other visible sign. Incubation period sixteen days. On dark-ground examination, *S. pallida* present. Treatment: Eight injections of 0.3 gram salvarsan and seven weekly injections of 1 grain mercury cream; completed September 14th, 1915.

Second Admission (May 3rd, 1916).—Signs of infection: (1) Typical Hunterian chancre on inner surface of prepuce near fraenum; (2) glands in groins hard and enlarged; (3) faint macular rash on chest. Incubation period about four weeks. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and five weekly injections of mercury cream; completed June 19th, 1916.

CASE VIII.

First Admission (September 3rd, 1915).—Signs of infection: (1) Typical papular erosive syphilitic sore on under surface of prepuce; (2) shotty glands in groins and neck. No other visible sign. Incubation period one month. Dark-ground examination, *S. pallida* present. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream; completed October 5th, 1915.

Second Admission (March 9th, 1916).—Signs of infection: (1) Typical indurated sore at coronal margin; (2) bubo in right groin, glands in left groin. Scar of old sore on under surface of prepuce. Incubation period uncertain. Dark ground examination, *S. pallida* present. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and six weekly injections of mercury cream; completed May 4th, 1916.

CASE IX.

First Admission (February 5th, 1915).—Signs of infection: (1) Typical primary papular erosive syphilitic chancre at fraenum; (2) glands in both groins enlarged and hard. No other visible sign. Incubation period uncertain. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream; completed April 10th, 1915.

Second Admission (May 25th, 1916).—Signs of infection: (1) Typical Hunterian chancre on inner surface of prepuce; (2) general adenitis. No other visible sign. Incubation period about four weeks. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and four weekly injections of mercury cream; completed July 30th, 1916.

CASE X.

First Admission (August 18th, 1915).—Signs of infection: Large papular erosive syphilitic sore on outer surface of foreskin. There was no enlargement of glands and no other visible sign. Incubation period two weeks. Dark ground examination, *S. pallida* present. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream; completed September 19th, 1915.

Second Admission (June 2nd, 1916).—Signs of infection: (1) Typical primary granulating syphilitic sore on under surface of prepuce; (2) glands in groins painlessly enlarged and hard. No other visible sign. Incubation period three weeks. Dark-ground examination, *S. pallida* present. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and three weekly injections of mercury cream; completed July 21st, 1916.

CASE XI.

First Admission (December 27th, 1914).—Signs of infection: (1) Scar of sore on glans penis; (2) slight general adenitis; (3) mucous patches on tongue and on right tonsil. No other visible sign. Incubation period uncertain. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream: completed February 23rd, 1915.

Second Admission (January 26th, 1916).—Signs of infection: (1) Two primary papular erosive syphilitic sores beneath prepuce; (2) shotty glands in groins. No other visible sign. Last exposure to infection five weeks before admission. Dark-ground examination. *S. pallida* present. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and seven weekly injections of mercury; completed March 21st, 1916.

CASE XII.

First Admission (July 4th, 1915).—Signs of infection: Non-inflammatory syphilitic oedema of skin of penis, hard nodule felt beneath phimosed prepuce. No other visible sign. Incubation period ten days. Dark-ground examination. *S. pallida* present. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream; completed August 17th, 1915.

Second Admission (June 15th, 1916).—Signs of infection: (1) Primary papular erosive syphilitic sore on inner surface of prepuce; (2) marked adenitis in both groins. Scar of old sore present. Incubation period three weeks. Wassermann test incomplete, Stern positive. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and five weekly injections of 1 grain mercury cream; completed August 7th, 1916.

CASE XIII.

First Admission (November 5th, 1915).—Signs of infection: (1) Typical Hunterian chancre at fraenum; (2) adenitis in groins and neck. No other visible sign. Incubation period one month. Treatment: Eight injections 0.3 gram salvarsan with intervals, and seven weekly injections of 1 grain mercury cream; completed February 8th, 1916.

Second Admission (July 8th, 1916).—Signs of infection: (1) Typical Hunterian chancre on right inner surface of prepuce; (2) adenitis in groins. No other visible sign; scar of previous sore at fraenum. Last exposure to infection about five weeks before admission. Wassermann and Stern tests negative. Treatment: Same as on first admission; completed August 24th, 1916.

CASE XIV.

First Admission (September 22nd, 1915).—Signs of infection: Two primary papular erosive syphilitic sores, one on inner surface of prepuce, one close to fraenum. No other visible sign. Incubation period not reliable. Dark-ground examination. *S. pallida* present. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream; completed December 6th, 1915.

Second Admission (July 16th, 1916).—Signs of infection: (1) Typical Hunterian chancre in coronal sulcus just to right of dorsal middle line; (2) general adenitis and a right bubo; (3) papular squamous rash over body and limbs; (4) mucous patch on inner side of upper lip. Scar of old sores present. Incubation period not reliable. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and six weekly injections of 1 grain mercury cream; completed August 30th, 1916.

CASE XV.

First Admission (November 6th, 1915).—Signs of infection: (1) Primary papular erosive syphilitic sore at fraenum; (2) indurated glands in groins. No other visible sign. Last exposure to infection five weeks before admission. Dark-ground examination. *S. pallida* present. Treatment: Eight injections of 0.3 gram salvarsan and five weekly injections of 1 grain mercury cream; completed December 7th, 1915.

Second Admission (December 19th, 1916).—Signs of infection: (1) Primary Hunterian chancre in coronal sulcus; second primary granulating syphilitic sore on under surface of prepuce; (2) glands in both groins enlarged and hard. No other visible sign. Last exposure to infection about six weeks before admission. Wassermann test positive. Treatment: Three injections of 0.3 gram salvarsan, one of 0.4 gram, three of 0.5 gram with intervals, and five weekly injections of 1 grain mercury cream. Treatment completed February 15th, 1917, when the Wassermann reaction was negative.

CASE XVI.

First Admission (January 9th, 1915).—Signs of infection: (1) Typical Hunterian chancre on inner surface of prepuce; (2) roseolar syphilide on chest. No other visible sign. Incubation period one month. Treatment: Four injections of 0.3 gram salvarsan and eight weekly injections of 1 grain mercury cream; completed March 2nd, 1915. On March 7th, 1916, the patient was readmitted with ulceration of both tonsils; no other visible signs. He was given a full course of eight injections of 0.3 gram salvarsan with intervals, and five weekly injections of 1 grain mercury cream. He was discharged to duty on May 3rd, 1916.

Second Admission (October 2nd, 1916).—Signs of infection: (1) Early primary papular erosive syphilitic sore in left of coronal sulcus; (2) glands in groins painlessly enlarged and hard and shot-like. No other visible sign. Incubation period two weeks. Treatment: Three injections of 0.3 gram, one of 0.4 gram, and three of 0.5 gram salvarsan with intervals, and

six weekly injections of 1 grain mercury cream; completed December 9th, 1916. The Wassermann reaction was incomplete both before and after treatment.

CASE XVII.

First Admission (December 4th, 1915). Signs of infection: (1) Balanitis, a hard nodule to be felt under foreskin about level of fraenum; (2) glands in groin shot-like and enlarged. No other visible sign. Last exposure to infection about six weeks before admission. Treatment: Eight injections of 0.3 gram salvarsan with intervals, and seven weekly injections of 1 grain mercury cream; completed January 25th, 1916.

Second Admission (April 12th, 1917).—Signs of infection: (1) A typical primary papular erosive syphilitic sore occupied fraenal site; (2) painless shotty adenitis in left groin. No other visible sign. Incubation period one month. Dark-ground examination. *S. pallida* present. Treatment: Seven weekly deep subcutaneous injections of 0.6 gram salvarsan and five weekly injections of 1 grain mercury cream; completed May 28th, 1917. The Wassermann reaction was negative both before and after treatment.

CASE XVIII.

First Admission (May 22nd, 1915).—Signs of infection: (1) Small papular erosive syphilitic sore on under surface of foreskin; (2) glands in both groins enlarged; (3) macular rash on body. No other visible sign. Incubation period one month. Treatment: Eight injections of 0.3 gram salvarsan and six weekly injections of 1 grain mercury cream; completed July 13th, 1915.

Second Admission (March 2nd, 1917).—Signs of infection: (1) Phimosis, unable to retract foreskin; a clean indurated granulating syphilitic sore on anterior surface of skin of penis; (2) glands in groins painlessly enlarged and shot-like. No other visible sign. Incubation period eighteen days. Treatment: Six weekly injections of 0.6 gram salvarsan, deep subcutaneous; five weekly injections of 1 grain mercury cream. Treatment completed May 1st, 1917. The Wassermann reaction was negative both before and after treatment.

The cases in this series are not supported by the bacteriological findings and serum tests, and so do not comply with the conditions laid down for Series J, still the likelihood of the correctness of the diagnosis is enhanced by the fact that again, as in the cases given in Series I, the two distinct attacks of syphilis have been seen in all the cases here recorded by the same observer. The cases were seen, the notes checked, and the treatment of each patient carried out by me at the time of his first and second attack.

The above 28 cases of reinfection occurred in a series of 10,500 cases of syphilis treated in No. — General Hospital during the past two years.

For the Wassermann tests and dark-ground examinations I am indebted to Captains A. Dawson and A. T. MacWhirter, R.A.M.C., and I wish to thank Sergeant G. T. Platford, R.A.M.C., for the trouble he has taken in summarizing the notes on the cases given in Series I and II.

THE MEDICINAL TREATMENT OF GONORRHOEA.

BY

MAJOR H. C. DONALD, M.B., C.M., F.R.C.S. EDIN.,
R.A.M.C.(T.F.),

AND

CAPTAIN A. M. DAVIDSON, M.B., CH.B. EDIN.,
M.D. MANITOBA, R.A.M.C.

A QUESTION which was frequently asked by many medical officers who visited a certain venereal hospital for the purpose of inquiring into the routine methods of treatment was, "Is irrigation into the bladder any better than flushing of the urethra from within by the use of medicines?" With a view to deciding this question permission was granted to treat cases with medicine alone.

Routine treatment as carried out generally in the above mentioned hospital in ordinary cases meant three irrigations a day into the bladder, prostatic massage, and instrumental treatment where indicated.

Method of Treatment.

The intention at first was to have a control series of one hundred patients on routine irrigation treatment and another series of one hundred patients on medicinal treatment. When, however, volunteers were called for every patient volunteered for the medicinal treatment, and it was then decided, in order to have the full confidence of the patients, to give every patient medicinal treatment. Accordingly the whole division, consisting of about two

hundred patients, commenced the treatment, which consisted of diuretics in the early stages, chiefly Fournier's formulae and the usual potassium citrate, hyoscyamus, and buchu mixture, and in the later stages mixtures containing the oleo-resins (oil of copaiba, sandalwood oil, and oil of cinnamon). Fournier's formulae were as follows:

1. Nitrate de potasse	0.50 gram
Douce-amère (woody nightshade, <i>Solanum dulcamara</i>)	10.00 grams
Chien dent (<i>Agropyrum repens</i>)	10.00 "
Infused in a litre of water.	
2. Réglisse pulvérisée	20 grams
Racine de Guimauve pulvérisée	10 "
Gomme arabique	60 "
Sucre de lait	60 "
Nitrate de potasse	10 "

Make in doses of 10 grams per litre of water, to be taken in twenty-four hours.

The medicine was taken six times a day at the following hours: 6 a.m., 8 a.m., 11 a.m., 2 p.m., 5 p.m., and 8 p.m.

The patients paraded under their respective sergeants, marquee by marquee, at the above hours, and as they filed into the treatment hut they received their medicine in their basins, and, after passing behind the irrigation trough, they placed their basins on the shelf. The drinking of the medicine was carried out under the strict supervision of the wardmaster, so that no one missed taking his dose. After taking the medicine, the patients washed the glans penis and prepuce by means of swabs soaked in a solution of potassium permanganate contained in the irrigation buckets, and afterwards they washed their hands.

They received no other treatment except when urethral infiltrations were present, in which cases dilatation was carried out. No vaccine or prostatic massage was given.

The patients were weighed every six days in order to ascertain if the imbibing of large quantities of fluid affected their fitness for duty. It, however, made no appreciable difference.

Clinical Observations.

Compared with irrigation treatment, it was found that:

Discharge.—The urethra remained purulent for a much longer period and never became "bone dry."

Condition.—Oedema persisted for a longer time.

Pain.—Complaints of pain persisted for weeks. Severe pain was complained of in many more cases than if the patients had been on irrigation treatment. This was very striking.

Frequency.—Owing to the large amount of fluid imbibed frequency of micturition was naturally greater (ten to twenty times a day on the average).

Bowels.—These were naturally looser than usual.

Progress and Complications.

More cases became subacute and chronic, and seemed to have a chronic oedema, which does not occur under irrigation treatment. There were more palpable periurethral infiltrations in the form of follicles and periurethritis. There was less tendency for the discharge to cease and the urethra to become dry than under irrigation treatment. The routine urine test did not show the same progress. In spite of the large amount of fluid taken, shreds were easily observed in the urine, which would suggest that there was more posterior urethritis. The treatment did not prevent the development of the same percentage of epididymitis (acute and subacute) as occurs under irrigation treatment. The same was true of arthritis.

After carrying out this treatment for two months we were obliged to resort to the old methods of treatment, and it was noticeable that many resistant cases cleared up rapidly. With dilatation the subacute inflammation of the urethra quickly subsided. Pus could still be massaged out of the prostate after weeks of medicinal treatment.

Statistics.

At the time of returning to irrigation treatment it was found that there were more chronic cases in the division than ever before. Only 78 men had been discharged to duty on medicine alone in the period of two months, as against four times as many discharged in a similar period

under irrigation treatment. Of these 78 men, 65 per cent. were cases of relapse either after treatment in this hospital or other hospitals. Only 24 per cent. were primary infections.

As far as can be at present ascertained, the relapse rate for this series of men discharged after medicinal treatment only is already higher than that of any other series.

The effect of medicine in prolonging the stay in hospital is clearly shown by a comparison between two series of similar composition—one series treated on the routine irrigation system, and the other by both irrigation and medicine (but not both together).

It was found that in the latter series the number of days in hospital for all the cases was increased by 14; the treatment of primary infections was lengthened by 18 days; the treatment of subsequent infections by 20 days; and the treatment of relapses from this hospital or other hospitals by 7 days.

CONCLUSION.

To sum up, medicinal treatment from a clinical and statistical point of view undoubtedly does not help but retards the cure of gonorrhoea, and tends to produce chronicity.

OPERATIONS ON THE NASAL SINUSES CARRIED OUT THROUGH A TEMPORARY OPENING IN THE SEPTUM (TRANS-SEPTAL).

By NORMAN PATTERSON, M.B., B.Ch., F.R.C.S.,

ASSISTANT SURGEON, LONDON HOSPITAL; SURGEON, THROAT HOSPITAL,
GOLDEN SQUARE, ETC.

THERE are two routes by which the ethmoidal cells may be approached. By far the most usual is through the nose; only in rare instances is the disease attacked from the outside through a skin incision. The external operation may be adopted in cases where there is an ethmoidal mucocele, suppurating or otherwise, causing a swelling in the neighbourhood of the inner canthus; in dealing with a diseased ethmoidal labyrinth and frontal sinus at one and the same time; in removal of tumours, innocent or malignant (for example, exostosis, sarcoma); and, in rare instances, where a very thorough exposure of the ethmoidal cells is called for. The external operation has the advantage that anatomical landmarks can be more clearly defined, and the diseased cells can be dealt with under direct vision. Its main disadvantage is that a scar is left on the face, and that normal non-infected tissues are of necessity opened up. The advantage of the nasal route of approach is that there is no resulting scar, and that the infected area is not reached through healthy tissues. Its main disadvantage is that it is impossible to get a really good view of the field of operation. Much depends on guess work and the "feel" of the tissues under the instrument.

I have endeavoured to improve on the route of approach to the ethmoidal cells, and, incidentally, to the sphenoidal sinus, by adopting the plan here described.

In viewing the region of the middle turbinate and ethmoidal labyrinth from the corresponding nostril, one is met with the difficulty that it is impossible to obtain a direct view of the field of operation.

The anterior end and a portion of the lower border of the middle turbinate is brought well into the field, but, even after this structure has been removed, only a very unsatisfactory view of the ethmoidal region is obtained. It occurred to me that the structures in this neighbourhood might be brought, so to speak, "under the eye of the surgeon" by approaching them through the opposite nostril. (No one can have failed to remark on the excellent display of the opposite side of the nose revealed through a large septal perforation.) The view becomes much more direct, and, in the case of the anterior ethmoidal region at any rate, a more or less surface view becomes possible (see Fig. 1). To obtain this view it is necessary, of course, to make an incision through the septum, and it is of importance that the septal aperture be only a temporary one.

I shall now describe the various methods I have tried in making this temporary passage through the septum.

The simplest plan of all is to carry an oblique incision through the whole thickness of the septum. This should be commenced about half an inch from the nasal orifice, and carried from above downwards and backwards to the length of about three-quarters of an inch (see Fig. 2). If one ethmoid only is involved the incision through the septum should slant from before backwards, so that the mucous membrane on the side corresponding to the diseased ethmoid is divided at a point slightly posterior to that on which the knife is entered. This obliquity makes coaptation easier when the septum is united at the completion of the operation. If both ethmoids are to be dealt with, then the incision through the septum should be strictly at right angles to the cartilage. Through this incision the blades of the speculum are introduced and a view of the outer wall of the opposite nasal cavity obtained. The objections to this procedure are: (1) There is a considerable amount of resistance encountered in introducing the speculum through the septal incision, and some difficulty is experienced in keeping an ordinary instrument of the Thudichum type fully open. (2) The portion of the septum behind the incision is displaced by the speculum against the inferior turbinate, preventing the full opening of the instrument. This, to some extent, may be overcome by removing the anterior portion of the inferior turbinate. (3) However pliable the cartilage may be, the bony septum posterior to it can be displaced only to a slight degree. These objections may be overcome by making two incisions through the whole thickness of the cartilaginous septum, extending backwards from either end of the primary oblique incision, and thus creating a sort of temporary swing door (see Fig. 2, dotted lines). It is preferable, however, to carry out, as a preliminary procedure, a submucous resection of the septum. If this plan is followed, there are two or three alternatives any one of which may be adopted. It is possible, especially if the ethmoidal disease is one-sided, to approach it in the following way: First of all, carry out a submucous resection, making the preliminary incision on the side opposite the disease. It is important to carry the bone removal high up, and, if the sphenoidal sinus is to be examined or treated, to remove the vomer in the neighbourhood of that sinus. After the submucous resection has been carried to completion an incision is made parallel to the preliminary incision, and from a quarter to half an inch behind it, through the opposite flap.

When the ethmoidal operation has been completed the edges of both incisions can be brought together by a few fine sutures. The fact that the incisions are not opposite each other should prevent a permanent fenestra in the septum, and suturing may not be necessary. A plug of oiled silk should, however, be inserted into the anterior part of the nose on both sides, so as to keep the layers in apposition. It is well, before inserting the plugs, to make a small opening in the posterior portion of the pocket formed by the two flaps, so as to avoid the accumulation of blood and the formation of a haematoma. As the case is one of suppurative nasal disease it is well to avoid packing the cavity of the nose proper; an anterior plug kept in for twenty-four hours will do no harm.

FIG. 2.

In cases where both ethmoids are diseased, by making the incisions through the septal flaps nearly opposite but

not quite opposite each other, the speculum may be worked from either side of the nose through the opening so formed, and both ethmoids can in this way be dealt with. An objection that must be raised to this method of carrying out a submucous resection and operation on the ethmoids at one and the same time is, that it opens up the area between the flaps to infection from the diseased sinuses, but so far this complication has not occurred in any cases operated upon.

The best method of all, if the consent of the patient can be obtained, is to perform a submucous resection, and after a period of ten days or longer, follow it up by an operation on the ethmoid. The main objection to this is that the patient has to submit to two operations. The septum, however, may already have been resected, or it may be so badly deflected as to require a preliminary resection, in which case all gross polypoid disease should be dealt with at the same time, and the middle turbinates, if still present, should be partially or completely removed. This will leave the ethmoidal galleries alone to be treated at the second operation.

When the septum is thoroughly healed, and all reaction as the result of the first operation has passed off, the surgeon then proceeds as follows: An oblique incision is carried through the two united layers of muco-perichondrium. A speculum with long blades of the Thudichum type, such as is used in submucous resection, or Killian's long-bladed speculum, is then passed through the opening. It may be found desirable to have one of the blades shorter than the other (see Fig. 2). After the suppurating cells have been dealt with the incision through the septum is brought together with several fine sutures, a special needle being used for this purpose. If this is carefully done there will be no resulting perforation.

I have found that the main trouble in carrying out this operation on the ethmoids is haemorrhage. This is of course greater if a general anaesthetic is employed. It may, however, be limited by adopting the following suggestions:

1. It is most essential before operating on the ethmoid proper by this method to remove all visible polypi, and generally the middle turbinates if they are still present. (In some cases it may be desirable to conserve more or less of the middle turbinates.) This is accomplished in the ordinary way by means of snare and forceps. These procedures should be carried out some days before the main operation, and, as above stated, the septum resected at the same time.

2. Thorough preliminary packing with cocaine and adrenalin, a half to three quarters of an hour before the operation, coupled with a hypodermic injection of morphine and atropine, or atropine alone. In cases where a local anaesthetic only is employed, a preliminary injection of morphine is very useful. Chloroform is the best anaesthetic.

3. Where both ethmoids are involved the operator should frequently change over from one side of the nose to the other, and the side where for the time being the operation is not actually taking place should be firmly packed with strips of gauze saturated with cocaine but squeezed out nearly dry.

4. The head should be elevated as much as possible to reduce congestion. Probably the sitting posture, as advocated by Waggett, de Prenderville, and others, would be found useful.

5. Calcium lactate may be administered beforehand.

I have found it possible in this way to clear out under vision the entire ethmoidal region. It is surprising how good a view of the ethmoidal bulla is obtained, and also of the cell cavities as they are opened up. It is quite possible to examine individual cells and curette out their mucous linings or polypoid contents with a small spoon or ring knife. Luc's forceps, Grunwald's forceps, and occasionally a bent probe, will all prove useful in breaking down the partitions between diseased cells. The limits of the disease can be defined with considerable accuracy. After removal of the cellular portion of the ethmoid the orbital plate or os planum is brought into view, and care must be taken to avoid injuring it. Of course the further forward the field of operation the better the view. The agger cells are in an excellent position for examination and treatment.

This method will also be found of use in exploration of, and operation on, the sphenoidal sinus. By employing it

a view can be obtained of the posterior end of the middle turbinate, and the posterior third or half of this body can be removed without interfering with the anterior portion. In this way the opening of the sinus may more readily be brought into view. Suppuration in the posterior ethmoidal cells will perhaps be discovered, and if found can be dealt with.

Operation on the frontal sinus for the improvement of drainage, on the lacrimal sac (intranasal dacryocystostomy), and inspection of and operation upon the antrum, may be carried out by this route. In the case of the antrum the middle portion only of the inferior turbinate need be removed; moreover, it will be found comparatively easy to remove the lowest part of the antromaxillary wall with a chisel. A good view of the interior of the cavity will be obtained; polypi or a foreign body can be dealt with.

Structures seen from an unfamiliar point of view may at first be recognized with some difficulty, but a little practice will accustom the surgeon to the altered orientation. He should correct his impressions by occasional examinations through the nostril on the same side as the disease. When working in the posterior region of the nose this is most essential, as structures situated near the septum will be better seen when viewed from the same side. It is always well to remember that in these ethmoidal cases disease works great changes, and that anatomical landmarks present in health are often conspicuous by their absence. One advantage of working obliquely across the nose is that the point of the forceps or end of the ring knife is directed towards the orbit instead of towards the roof of the ethmoidal galleries and cribriform plate. My results in dealing with cases by this method have been very encouraging, and I hope at a later date to publish some of them.

DOSAGE IN THE THERAPEUTIC ADMINISTRATION OF THYROID GLAND SUBSTANCE.

BY

A. E. CARVER, M.D. CANTAB., M.R.C.P. LOND.,

HONORARY PHYSICIAN, WESTERN AUXILIARY MILITARY HOSPITAL, TORQUAY; LATELY SERVING WITH THE SALONICA FORCES.

IN current medical literature reference is made by various writers to treatment by means of thyroid gland substance, termed "thyroid extract." This term, however, has no exact meaning, for it does not appear either in the *Pharmacopoeia* or in other works of like nature, and it is susceptible of different interpretations in different circumstances.

Thus it is probable that, if thyroid extract or *ext. thyroidei sicc.* be prescribed in powder, the *thyroideum siccum* (*B.P.*) will be dispensed, of which one part is equivalent to about five parts of the fresh gland; but that, if the same prescription be ordered in tablet, it will be supplied in the form of a preparation by one of the big drug houses, whose tablets are usually made up in strength approximately equivalent to the fresh gland, that is, about one-fifth the strength of the official preparation.

In this way the treatment of patients suffering from thyroid insufficiency is liable to be ineffective, as is well illustrated by a case which came under my care four years ago.

A woman, aged 38, consulted me on account of inability to discharge her duties as a nurse; she was suffering from well marked myxoedema. She complained of a variety of disturbances, especially at night, and the classic features of the disease were present. Her weight was 11 st. 7 lb. I ordered *extract. thyroidei sicc.* in tablets in doses increasing up to 18 grains daily, which she took for three months without any improvement. Upon inquiry I ascertained that the tablets supplied were those put up commercially, and that the patient had therefore been receiving the equivalent of only about 3½ grains of the official preparation daily. Treatment was then discontinued for a week or two, after which I altered the prescription to *thyroideum siccum* (*B.P.*), increasing up to gr. v—in cachet—of which three were taken daily. The result was immediate and immense improvement. The supraclavicular masses began to disappear, her weight decreased until she was only 9 st. 9 lb., the nocturnal distress ceased, and the facial and general aspect changed; but any omission in taking the thyroid has been followed by increase in weight and recurrence of symptoms. The daily dose of *thyroid. sicc.* (*B.P.*) taken by this patient is the equivalent of about 75 tablets of 5 grains each as commercially prepared.

Hence it is seen that there are two sources of possible error in the administration of thyroid gland substance:

1. Through the fact that in the official preparation the substance is presented in concentrated form, whilst in the products of some of the large commercial houses it is presented in approximately the strength of the fresh gland.

2. Through the use of the term "*ext. thyroidei*," which indicates neither of the above preparations specifically, but leaves to the chemist the decision as to which of them shall be supplied.

It may be argued that in the case quoted the chemist was at fault in dispensing the commercial tablets to my prescription; but, in view of the vagueness of the term "*thyroid extract*," this is not sound reasoning, and I have since ascertained from other chemists that they would have dispensed the prescription in like manner.

It is to be noted that in the *B.P.* 1914 the official dose of *thyroideum siccum* is given as ½ to 4 grains, instead of 3 to 10 grains, as in the *B.P.* 1898. In neither case is there any suggestion as to how frequently the dose may be repeated, and the change introduces another factor that may contribute towards ineffective treatment.

A CASE OF CONTRACTED PELVIS: CAESAREAN SECTION THIRCE.

By ARTHUR CROOK, M.R.C.S., L.R.C.P.,

NORWICH.

THE following case is of sufficient interest to be placed on record, I think. For economy of space I have omitted many interesting details, bearing on the questions of the effect of scarlet fever desquamation on the healing of operation wounds, the lochia after Caesarean section operations, and the comparative values of silk and catgut suture for the uterine wound.

First Operation.

The patient when first seen, October 27th, 1914, was a primipara aged 25. She had been in labour over thirty hours in the hands of a midwife, who had sent for a doctor; he, under an anaesthetic, had succeeded in drawing down a foot outside the vulva, and then requested me to see the case. I found, as well as the foot, the umbilical cord (not pulsating) protruding. The pelvis contracted, with a true conjugate of about 2½ inches; pulse and temperature were normal.

Considering that the uterus was most probably infected, and that embryotomy would be most difficult and dangerous, I considered abdominal hysterectomy would give her the best chance of recovery, and she was removed to the Norfolk and Norwich Hospital for that purpose. There it was decided by Mr. Everett, under whose care she came, to allow a chance for future pregnancies by performing conservative Caesarean section. This was done, and though the patient had, on the second day after this operation, a pulse of 140, and for a week elevation of temperature due to sepsis contracted in labour, she made a good recovery.

Second Operation.

On November 25th, 1915, she came to me, then eight months pregnant, and on December 16th she was admitted into the Norwich Maternity Institution under my care. The following pelvic measurements were noted:

Between the A.S.S., 10 in.
Between crests, 10½ in.
External conjugate, 6½ in.
Diagonal conjugate, 3½ in.
Transverse of outlet, 2½ in.

On December 19th I performed Caesarean section, delivering her of a living female child weighing 7½ lb. A few adhesions were found on the surface of the uterus, but no signs of a scar from the first operation. The patient progressed normally for the first three days, but on the evening of the fourth developed a definite attack of scarlet fever, which was followed by total desquamation a fortnight after. Notwithstanding this she made a good recovery, and was discharged with her child on January 12th, 1916.

Third Operation.

On June 8th, 1917, she was again admitted to the Norwich Maternity Institution pregnant, with labour due on or about June 16th. She requested me on this occasion to sterilize her.

On June 10th I performed Caesarean section, delivering her of a living female child of 6½ lb. Slight adhesions were seen, and a distinct scar was noted in the uterine wall. The Fallopian tubes were ligatured and divided, and the peritoneum stitched over each end with catgut.

The patient, who nursed her child from the third day, was discharged on the twentieth day after operation quite well.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SALICYLIC IONIZATION AS A PALLIATIVE IN MULTIPLE NEUROFIBROMATA OF THE SPINAL CORD.

SOME eighteen months ago a nurse, aged 49, the victim of multiple neurofibromata of the spinal cord (von Recklinghausen's disease), came to me in despair. She had recently been operated upon and a number of small fibromata had been dissected from the spinal nerve roots. As, however, it was found impossible to remove more than a certain proportion of the very numerous little tumours, she experienced little benefit from the operation. The pain and stiffness in the back continually increased; she walked lamely and became liable to sudden loss of power in the lower extremities, causing her to fall down in the street as if struck. She had to cease work and life became a burden to her. The surgeon told her he could do no more.

I searched the literature in the nearest medical library for information as to the treatment of this obscure disease. No suggestions were forthcoming. "If operation fails the case is hopeless" was the general verdict. In desperation, her condition being so miserable it could scarcely be made worse, I suggested she should try electrical treatment. After a six weeks' course of salicylic ionization she was wonderfully improved; the pain and stiffness had vanished, the limbs had regained their strength, and the nodules, though still tender on pressure, caused little or no inconvenience.

Shortly afterwards she was once more able to take up her work as a masseuse, and from that time up to the present she has kept reasonably fit. At the moment, in addition to a large amount of private work, she attends two military hospitals, treating from twenty to thirty cases daily. She still finds it necessary to keep up the ionization treatment—without it pain and stiffness return—but a couple of applications a week are sufficient to keep the trouble at bay.

I have now advised her to try potassium iodide in place of the sodium salicylate to attempt to bring about actual disappearance of the nodules. The patient attributes her present well-being entirely to the electrical treatment, and since instead of being a hopeless invalid she is now a useful member of the community, it seemed well to place the case on record for the benefit of others similarly afflicted.

G. H. HICKLING, M.D., D.P.H., B.Sc.

Marple Bridge, Derbyshire.

A CASE OF HAEMATEMESIS AND MELÆNA NEONATORUM WITH RECOVERY.

ON May 19th, 1917, Mrs. —, a primipara, who had suffered during the earlier part of the puerperium from continual vomiting, and during the latter part from albuminuria, was delivered of a male child at 10.30 p.m. Apart from a delayed second stage, when forceps were applied under an anaesthetic, the labour was normal. The child when born had extreme moulding of the head, cried feebly, and its respirations were shallow, but stimulation by slapping made it cry lustily and respiration became normal.

ON May 21st, at 2.30 a.m., twenty-eight hours after birth, attention was drawn to the child by a gurgling sound, and it was found that it had vomited blood. This continued on and off until 3.30 a.m., by which time 8 to 10 ounces had been vomited. At 3.45 a.m. there was recurrent hæmatemesis of another ounce, and the child was given 1 minim of tincture of opium in half an ounce of water by the mouth. At 5 a.m. there was a further hæmatemesis of another ounce, and again the child was given 1 minim of tincture of opium. After this it went to sleep, and there was no further hæmatemesis.

At 9 a.m. Dr. Charles R. Box saw the infant, and advised subcutaneous injections of human serum; meantime a large tarry stool streaked with bright blood was passed. At noon the first subcutaneous injection of 10 c.cm. human serum was given in the abdominal wall, and a gelatin mixture (gr. x in 3ss) given by the mouth every two hours throughout the day.

ON May 22nd the stools were still tarry but not streaked with bright blood. Another subcutaneous injection of 15 c.cm. human serum was administered, and half an ounce of a 10 per cent. solution of glucose given every two hours alternately with the gelatin mixture, by mouth. ON May 23rd the stools were tarry; the glucose solution and gelatin mixture were continued, and 10 c.cm. serum injected. Next day the stools were still tarry; no serum given, but glucose solution and gelatin mixture were continued. ON May 25th the stools were normal. Another 10 c.cm. serum injected. The glucose solution and gelatin mixture were discontinued, and two ounces of No. 1 humanized milk substituted every two hours.

Jaundice was evident from May 22nd to May 26th, when it gradually disappeared. After May 24th the child was perfectly well, and took his feeds well. No. 2 humanized milk was substituted for No. 1 on June 4th, and he gained on the average over one ounce in weight daily.

Abbey House, Kenilworth.

WM. MARRIOTT.

HYPERPYREXIA IN ENTERIC FEVER.

L. B., aged 28, male, an Italian ice-cream vendor, was seen by me for the first time on June 25th. He had been feeling "out of sorts" for some days, suffering from headache and diarrhoea. His temperature at my visit was 103.6° F., the belly was tumid, the tongue furred, and some suspicious spots were seen on the abdomen. A diagnosis of typhoid fever was made, and subsequently confirmed by the Widal test. The stage of the illness seemed to be about the beginning of the second week. For the next six days the evening temperature remained at about 103° F., there was considerable bronchitis, and diarrhoea was at times troublesome. On the evening of July 2nd the temperature fell to 101° F., but by midday of July 3rd it had risen to 104.2° F. A sponging with cold water had no effect, as two hours later it had reached 105.6° F. The patient was then rubbed over with ice, which brought the temperature down to 103° F. It immediately began to rise again, attaining 106° F. in two hours. An ice-pack reduced it to 103.2° F., only for it to shoot up again to 107.2° F., when the patient succumbed.

Death from or accompanied by such pyrexia is comparatively rare in enteric fever, and I have ventured to think that the circumstance is worth recording.

F. M. FONSECA, F.R.C.S.I., D.P.H., L.A.H. Dubl.,
Assistant Surgeon and Anaesthetist, Ebbw Vale
Hospital.

EXCISION OF CAECUM: FATAL GASTRIC DILATATION.

E. S., aged 28, an Indian, was admitted on April 28th, 1917, for abdominal pain, especially in the right iliac fossa, of eight months' duration. He had no acute attacks, but the pain was gradually getting worse; there had been no attacks of obstruction.

Examination showed a hard nodular mass in the right iliac fossa, diagnosed as caecal tumour, malignant or tuberculous. ON May 2nd, 1917, a large pararectal incision was made, and the tumour was found to be an extensive carcinoma which had become adherent on the outer side to the parietal peritoneum as well as the omentum. The caecum, ascending colon, and hepatic flexures were excised with the last few inches of the ileum, and lateral anastomosis performed. In mobilizing the caecum and colon the peritoneum on the outer side was of necessity cut rather further than usual from the bowel, so that some but not a great deal of tension was necessary to bring the parietal peritoneum and mesocolon into apposition to peritonealize the raw area.

The patient stood the operation well. The next day, however, his pulse began to fail, there was no sign of peritoneal infection nor bleeding. There was no vomiting at any time. The pulse gradually failed and he died. He was kept sitting up and in this position did not show signs of dilatation of the stomach.

At the *post-mortem* examination all was found well with the anastomosis and there was no hæmorrhage, the stomach and that part of the duodenum proximal to the superior mesenteric artery was greatly dilated and contained all the fluid the patient had taken. Whatever may be the usual cause of acute post-operative dilatation of the

stomach, there can be no doubt that in this case the tension on the mesocolon had caused the superior mesenteric artery to obstruct the duodenum and produce acute dilatation and death without vomiting.

C. H. BRODRIBB, Major I.M.S.,
Medical Officer in Charge of the Civil Hospital,
Secunderabad.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

VICTORIA WAR HOSPITAL, BOMBAY.

GUNSHOT WOUND OF LIVER: SECONDARY HAEMORRHAGE:
LIGATURE OF BRANCH OF HEPATIC ARTERY:
RECOVERY.

(By T. S. Novis, F.R.C.S., Major I.M.S., Surgical
Specialist to the Hospital.)

Lieutenant M. N., Turkish prisoner, was struck by a rifle bullet, which entered his chest in the seventh right costal interspace, 1 in. outside the nipple line, and passed out below the costal margin in the posterior part of the right flank, wounding the liver and right lung. At first his progress was satisfactory and his wounds had almost healed when transferred to a hospital ship three weeks later.

On the first day of the voyage, during dinner, he was seized with faintness and exhibited all the symptoms of internal haemorrhage. The abdomen was opened through the right rectus and the wound in the liver packed, the ends of the gauze were left protruding through the upper end of the incision, which was closed after the peritoneal cavity had been emptied of blood, and a counter-drain introduced in the flank. The patient quickly rallied, and the packing was removed after four days. There was no haemorrhage.

On arrival in Bombay he was admitted to the Victoria War Hospital. He was very ill, and had a sinus at the upper end of the abdominal incision which was discharging a considerable quantity of brown pus. The temperature showed an evening rise, which became more marked after a few days, and was thought to be due to a small haemothorax on the right side of his chest having become septic; this, however, proved on exploration to be sterile. As his condition did not improve and the temperature assumed a more septic type, it was deemed advisable to open up the sinus running down to the liver and introduce a small drainage tube.

The symptoms were relieved, but four or five days later a severe secondary haemorrhage occurred, which was checked by plugging but not permanently stopped. Under anaesthesia the abdominal sinus was opened up by an incision extending back below the costal margin to the counter-opening in the flank; the scar in the seventh intercostal space, which was bulging, was also opened. Haemorrhage was very free from both openings, which communicated; the blood clot was hastily removed, and the wound in the liver packed with gauze soaked in adrenalin. Two days later, when the packing was removed, after loosening with hydrogen peroxide, all haemorrhage had ceased. The wound was washed out with hydrogen peroxide and lightly packed daily.

He appeared to be doing well for a week, when another severe secondary haemorrhage occurred during the night, which was temporarily controlled by packing. When I saw the patient he showed signs of serious loss of blood, and his condition was critical. I resected six inches of the eighth rib, and divided the diaphragm and liver tissue between the chest wall and the track of the bullet; having powerfully retracted the seventh from the ninth rib, I was able to see and, by understitching, secure a large branch of the hepatic artery, which was bleeding freely, and had been no doubt the source of haemorrhage from the beginning. He was transfused intravenously on the table, and again into the cellular tissue of the axilla on the evening of the operation.

From this time onwards his recovery was continuous though slow, and he eventually left the hospital with both wounds healed, looking stout and well.

Reviews.

THE TREATMENT OF DIABETES.

THE book with this title by Dr. ELLIOTT P. JOSLIN,¹ Assistant Professor of Medicine at Harvard, is a full and authoritative account of the modern treatment of diabetes on the lines laid down by Dr. F. M. Allen. It is well up to date in its practical and theoretical matter, as might be expected from a past laboratory worker who has now treated 1,300 diabetics. So clearly and refreshingly is this inherently difficult subject treated, that it becomes a singularly attractive problem. The present clash of arms is echoed by the dedication to the medical profession of the United States and her allies, and by the dictum on the opposite page that "it is desirable in peace, but a duty in war, for every diabetic patient to keep sugar-free. The food which the untreated diabetic patient wastes in a week would feed a soldier for a day."

Success in the treatment of diabetes, as in pulmonary tuberculosis, depends on early diagnosis, and accordingly the old rule always to examine the urine is insisted on to the extent that it should form part of the celebration of every birthday; the practical importance of systematic urinary examination in the detection of the disease in an early stage is shown by its discovery during life assurance examination in 11 per cent. of the author's male cases above the age of 10 years. A great advantage in Allen's fasting treatment is its simplicity, which obviates the need for complicated analyses of the urine and blood; in fact, the diabetic patient should, as part of his education, invariably test his urine, and as an example of the ease with which this can be effected reference is made to a boy aged 7 years who was able, not only to test his own urine, but that of other patients in the hospital, and to a girl of 4 who takes it for granted that the diet will be changed when she sees her urine give a positive Benedict reaction.

The dietetic treatment is successful only when the urine is free from sugar, for the diabetic patient's tolerance for carbohydrates increases when this occurs. In the past, the first year after the discovery of diabetes was the danger zone for the patient, as 68 per cent. of the deaths occurred in this period, whereas now the author's cases show a mortality of 14.8 per cent. only. This improvement is ascribed, in the first place, to the fasting treatment, and, secondly, to the preparation for the fast by the omission of fat, then by the restriction and omission of protein, and then the restriction of carbohydrates. It is seldom necessary to prolong the fast for more than four days, and if the urine is not sugar-free then, there is probably some complicating infection. The prevention of acid intoxication is aimed at by the omission of fats from the diet in the preparatory stage and by a return to it after the carbohydrates and proteins have been resumed. When, however, it threatens to become severe a definite campaign is initiated, and here as elsewhere detailed and clear directions are set out; large quantities of fluid in the form of coffee, tea, thin broths—two pints within every six hours—rest in a warm bed, the avoidance of constipation by enemas, and digitalis or caffeine hypodermically to sustain the circulation, are ordered. Alkalis are forbidden; this may appear a revolutionary doctrine, but the author, who was formerly its strenuous supporter, now gives good reasons for the view that the dangers outweigh the advantages of this treatment.

The practitioner who wishes to employ the Allen treatment should have this practical volume with its useful tables of diets at his elbow to fortify and inspire him with the author's hopeful confidence.

TRENCH FEET.

LIFE in the trenches from the point of view of trench feet is admirably illustrated in a little Italian manual on *Congelamenti*,² which may be translated "congelation," or,

¹ *The Treatment of Diabetes Mellitus*. By Elliott P. Joslin, M.D., Assistant Professor of Medicine, Harvard Medical School, etc. Second edition, enlarged and thoroughly revised. Philadelphia and New York: Lea and Febiger. 1917. (Med. 8vo, pp. xvi + 559; illustrated, 4.50 dollars.)

² *Congelamenti: Patogenesi e Cura*. By Piero Casali, Maggiore Medico, and Felice Pulle, Capitano Medico. With a Preface by Professor Luigi Devoto. Milano: Urico Hoepli. 1917. (Fcap. 8vo, pp. xvi + 364; 117 figures. L. 6.50.)

more freely, "lesions due to exposure to cold," written by Major CASALI and Captain PULLE of the Italian army. They remark that trench foot was described by Xenophon, who details in his *Anabasis* how he had to leave behind him on his march home certain soldiers with snow conjunctivitis and snow gangrene of the toes. Our authors give a full account of the pathogenesis and pathology of trench foot, and insert a great number of excellent photographs of the types of trenches in which the disorder is or is not liable to make its appearance. They distinguish three types of trench foot: That due to exposure to cold alone, that aggravated by the use of tight leg wear in wet trenches, and that aggravated by the presence of a dermatomycosis, the infecting agent being *Scopulariopsis koeningii*, in muddy trenches, associated also with the presence of *Sterigmatocystis versicolor*. Instructions for medical officers in charge and also for the men in the trenches are given, together with details of the prophylaxis and treatment of trench feet; the advice here given may be briefly summed up in the words "cleanliness and warmth." The book contains a great deal of practical information and advice, and should be of considerable service.

PHARMACOLOGY.

MORE than ever before pharmacology is now an experimental science. Professor JACKSON of St. Louis has performed a useful piece of work in bringing out a large and generously illustrated textbook of *Experimental Pharmacology*,³ in which the reader, who is presumably engaged in teaching or learning pharmacology, may see the technique of the experimental basis of the science expounded. At the beginning of the book is an account of the fitting up of the experimental laboratory, at the end a chapter on the shop-work that may be done by a skilled artisan in charge of the upkeep of the apparatus employed by the laboratory workers. The greater part of the text is concerned with experiments on experimental animals of all sorts to illustrate the pharmacological actions of drugs of all sorts, and is divided for convenience into 168 sections. It is clearly written in conversational style, and the text gains enormously in value from the admirable illustrations of every kind with which it is elucidated. The book is a first-class production and should be in the hands of all workers in pharmacological laboratories. It may be noted that the name of the drug termed "phloridzin" (page 457) should more correctly be spelled "phlorhizin."

*The Practitioner's Pocket Pharmacology and Formulary*⁴ is a compact and serviceable little volume into which Dr. FREYBERGER has contrived to crowd a vast amount of information about the use and abuse of all the important drugs and preparations of our own pharmacopoeia and that of the United States of America; in addition some foreign pharmacopoeias have been laid under contribution, and many extrapharmacopoeial drugs have been included. The drugs are arranged in alphabetical order, and each is discussed under such headings as "Properties," "Use," "Indications," "Dose," "Incompatibles," and the like, all as briefly as possible. Suitable formulae for administration are often given, and the treatment for cases of poisoning in the case of toxic drugs is indicated. The last seventy pages of the book are occupied with an index of indications and counter-indications, which begins by recommending taraxacum for abdominal plethora and ends with recommending salvarsan in yaws. The book is well up to date, and contains a great deal that should be of service to the discriminating practitioner of medicine or medical student, to whom it may be recommended.

NOTES ON BOOKS.

*Lecciones de Antropología*⁵ is a curious work, bearing the imprimatur of the Archbishop of Bogotá, in which the author seeks to define the causes or principles that regu-

late the nature, powers, and actions of mankind. He fills his well documented pages with references to the works of modern scientists, of modern philosophers, and of the philosophers of days long gone by. Among the latter it is particularly to St. Thomas Aquinas, the prince of thirteenth century theologians and peripatetic philosophers, that the author refers. And so it comes about that the pages of this book present, to any reader unversed in Roman Church views of scholastic philosophy, a curious yet coherent medley of fact and fancy relating to the nature of man and his various potentialities, his various concupiscible and irascible appetites, the origin of his soul (the author is a creationist, and refutes the pretensions of both the emanationists and the traducianists here). Passing on from the rarefied atmosphere of these intellectual subtleties, the reader finds accounts of stratigraphical and palaeontological chronology based on mere fact and described as "more or less plausible"; he finds, too, a discussion of the question whether primitive man was more degraded than we are ourselves, or a far nobler creature, as Milton and the late Duke of Argyll argued. The various sections of the book form an interesting study, alternating as they do between hard fact and divagations into speculative philosophy and theology. They have been published, it may be gathered from the preface, for the edification of students at the Bogotá College of Rosario.

MINISTRY OF NATIONAL SERVICE: MEDICAL DEPARTMENT.

We are officially informed that the Medical Department of the Ministry of National Service is organized as follows:

1. There is a Chief Commissioner of Medical Services with direct responsibility to the Minister. His office is in the offices of the Ministry in Westminster. His duties are to organize and administer the medical service of the Ministry, and to carry out its general policy. The Chief Commissioner is James Galloway, M.D., F.R.C.P., F.R.C.S.

2. The immediate task before this department is to make a medical survey of the male population of the present military age. For this purpose England, Scotland, and Wales have been divided into ten regions. In every region there will be a Commissioner of Medical Services whose duty it will be to represent the Medical Department of the Ministry in his region, to co-ordinate his work with that of the other representatives of the Ministry in the region, and to organize and administer the work of the medical service under the control of head quarters in London. The regions are as follows:

1. Northern, comprising Northumberland, Durham, Cumberland, Westmorland.
2. North-Western, comprising Lancashire and Cheshire.
3. Yorks and East Midland, comprising Yorkshire, Lincolnshire, Nottingham, Derby, Leicester, Northampton, Rutland.
4. West Midland, comprising Stafford, Warwick, Worcester, Hereford, Shropshire.
5. Wales.
6. South-Western, comprising Gloucester, Wilts, Somerset, Dorset, Devonshire, Cornwall.
7. East Anglia, comprising Norfolk, Suffolk, Essex, Cambridge, Huntingdon, Bedford, Bucks, Oxford, Berks, Herts.
8. South-Eastern, comprising Kent, Sussex, Hants, Surrey.
9. London.
10. Scotland.

Up to the present the following Commissioners have been appointed:

Sir James Porter, K.C.B., K.C.M.G.	South-Western Region.
Colonel C. & Tyrell, C.B.	London Region.
Sir Charles Bedford	South-Eastern.
Dr. T. Wardrop Griffith	Yorks and East Midland.
Dr. W. Bickerton Edwards	Wales.
Colonel W. H. Bull	West Midland.
Dr. Norman Walker	Scotland.
Dr. Hale White	East Anglia.
Dr. G. Redmayne Murray	North-Western.

The regions will be divided into recruiting areas, in each of which will be established one or more medical boards. The supervision of these will be the special duty of the regional commissioners.

The number of these medical boards will be approximately one hundred, and each of them will have as president a medical officer with some experience of these examinations of men. To assist him there will usually be four members of the medical board taken from a panel of local medical men to be selected by the Advisory Board on the advice of the Statutory Medical Committees. In cases

³ *Experimental Pharmacology*. By Dennis E. Jackson, Ph.D., M.D., Associate Professor of Pharmacology, Washington University Medical School, St. Louis. London: Henry Kimpton. 1917. (Med. 8vo, pp. 536: 390 figures, including 24 coloured plates. 20s. net.)

⁴ *The Practitioner's Pocket Pharmacology and Formulary*. By L. Freyberger, J.P., M.D. Vienna. London: W. Heinemann. 1917. (Fcap. 8vo, pp. 555. 12s. 6d. net.)

⁵ *Lecciones de Antropología*. By Julian Restrepo-Hernandez. Bogotá: Arboleda and Valencia. 1917. (Roy. 8vo, pp. xxii + 227. 1.30 dollars.)

presenting difficulty, such as those of suspected tuberculosis, heart disease, and unusual defects of vision, the presidents of medical boards will be empowered to obtain the opinions of specialists, and it is hoped that the staffs of general and special hospitals throughout the country may be able to render assistance in giving special opinions.

3. Hitherto men who, having appealed against the result of their medical examination, were granted a re-examination, have been sent for this purpose to special medical boards, of which there were three for England and Wales, namely, two in London and one in Leeds; also one for Scotland in Edinburgh. This system caused delay and entailed long journeys upon the men. In future, three medical assessors, appointed by the Local Government Board, will be attached to the appeal tribunals. Should the appeal tribunal on hearing a case decide that a medical re-examination is desirable, they will forward all the papers bearing on the case to the medical assessors, who will re-examine the man. The decision of the medical assessors will be final as regards the man's physical condition and gradation.

4. This gradation will be in four groups, namely:

Grade I, to consist of men who attain the normal standard of health and strength, and are capable of the physical exertion suitable to their age.

Grade II includes those who do not attain the standard of *Grade I* from various causes, such as deficient physical development or slight defects, but are yet fit for work of a less strenuous kind. Most of these are capable of improvement by training.

Grade I corresponds to Class A, or general service of the late classification, and *Grade II* to Classes B 1 and C 1, that is, to garrison duty abroad and at home.

Grade III includes those who from any cause are not suitable to undergo military training as combatants, although they may be quite fit for one of the auxiliary services connected with the army, and fit also for the work on which they are already employed or its equivalent.

Grade IV includes all those who are unfit both for military service and any work of national importance.

5. Another serious function of this department will be to consider the supply of students in the medical schools as bearing upon the future strength of the medical profession, and to determine whether it will be necessary to bring back to the schools men from the services where they are now serving in some non-medical capacity, and so reconstitute the body of students required to make good the wastage of the medical profession.

6. In order that this Ministry may be kept in close touch with medical opinion, and may have the co-operation of existing organizations, an advisory medical board has been created on which are represented:

Advisory Medical Board.

The Committee of Reference (of the Royal Colleges in England) by Charles Ryall, Esq., F.R.C.S.

The Central Medical War Committee by E. B. Turner, Esq., F.R.C.S., and T. Jenner Verrall, Esq., LL.D.

The Scottish Medical Service Emergency Committee by J. W. B. Hodsdon, Esq., M.D., President of the Royal College of Surgeons, Edinburgh.

The other members of the Advisory Medical Committee are Sir Donald MacAlister, K.C.B., M.D., Professor Arthur Keith, M.D., F.R.S., Colonel J. Arnall Jones, K.H.S., V.D., M.D., and Dr. Percy Edwards, Liverpool.

The Chairman is the Minister, Sir A. C. Geddes, K.C.B., and the Vice-Chairman the Chief Commissioner, Dr. James Galloway.

7. A manual of general directions for the guidance of presidents and members of medical boards has been prepared in order to ensure uniformity in the grading of men throughout the country.

In this manual a scheme is outlined by which every man is seen by each member of the medical board at some stage of his examination, while his final gradation is settled by the consensus of opinion of the members and president of the board. Hence there will be no ground for the complaints sometimes made that the president omits to consult the opinion of his board or even over-rides them.

When a man wishes to appeal against the gradation of the medical board he must lodge his appeal within five clear days of his examination, and will forward in duplicate any medical certificates he may wish to place before the tribunal. If the appeal tribunal after hearing the case decides that the claim is one in which they think medical re-examination is desirable, they will forward all the documents bearing on the case to the medical assessors

appointed by the Local Government Board, accompanied by the appeal tribunal's recommendation that the man should be re-examined. The medical assessors will inform the man of the date on which he should present himself for re-examination, giving at least three clear days' notice. A representative of the medical board which graded the man will be present at the meeting of the medical assessors of the appeal tribunal, if they desire it, in order to supply any information which may be required.

The medical assessors will communicate their decision to the chairman of the appeal tribunal, who will then make arrangements for the final adjustment of the man's case. The medical assessors will also give the man a card (known as A.F.W. 3291) showing the grade in which they have placed him.

8. There may arise in the course of the work of the medical boards and of the medical assessors questions of principle in the gradation suitable to men suffering from certain disabilities which cannot be decided by reference to the manual of instructions issued by the Ministry. In such cases the particular question will be stated in writing by the medical board or the medical assessors concerned and forwarded to the Secretary of the Ministry of National Service. The matter may then be placed before the Advisory Board of the Medical Department for an opinion. It will be within the power of the Ministry to refer questions involving special difficulty to medical men whose opinions may be judged to be of value on the particular subject in question.

THE CONTINUED TREATMENT AND TRAINING OF DISCHARGED SOLDIERS.

A new Army Council Instruction, No. 1531, of 1917, bearing date October 6th, 1917, has been issued in substitution for A.C.Is. 449, 626 and 795 of 1917, which are cancelled.

1. The Ministry of Pensions and War Pensions Committees established in the several counties and county boroughs and in certain large towns are charged with the duty of securing any medical treatment or training for industrial life that a discharged soldier may need. It is important, therefore, that officers i/c hospitals should be placed in relation with these Committees in a manner to be presently described.

2. With reference to A.C.I. 1912 of 1916, it must be borne in mind that so long as in-patient treatment is required, whether by means of curative manual exercises or by other means, and accommodation is available, soldiers will be retained in the appropriate hospitals.

On the termination of such treatment, if the men are considered to be unfit for further service, they will be brought before an invaliding board, but will not be discharged from hospital until the date of their actual discharge from the service, i.e., 21 days after their discharge has been approved by the invaliding board.

This procedure will be followed in the case of all soldiers in hospital who are about to be discharged from the service on medical grounds, except in limbless and mental cases, and cases of tuberculosis who accept sanatorium treatment.

Men who have been fitted with an artificial limb may be allowed to leave hospital before the expiration of 21 days provided that the relatives or friends of the man expressly state that they are able and willing to take him, and that satisfactory arrangements can be made to ensure his receiving his pay up to the date of his discharge from the army, i.e., 21 days after his invaliding board.

Mental cases which are to be discharged under the provisions of paras. 403-410 King's Regulations (see A.C.I. 1171 of 1917), and are suitable cases to be handed over to the care of friends, may, provided the friends are able and willing to look after them, be so handed over as soon as their discharge has been approved by the invaliding board.

Cases which are unsuitable to be handed over to friends may be sent to the asylum to which they are chargeable as soon as practicable after their discharge has been approved by the invaliding board, instead of being retained in the military hospital for the full period of 21 days.

Medical officers should, as far as possible, anticipate the date on which the patient will complete his in-patient

treatment in order that the soldier's documents may be obtained and the board held approximately 21 days before that date. This procedure will obviate any undue congestion of hospital beds.

A. Treatment of Cases on Discharge.

3. When a soldier has been approved for discharge from the army on medical grounds, and when he is subsequently discharged from the hospital, or command dépôt, or other unit in the case of a man not in hospital, some further treatment as an out-patient (or in special cases, e.g., tuberculosis or paraplegia, as an in-patient) may be necessary. Where out-patient treatment is required it may often be suitably afforded at a military hospital or in a V.A.D. or Red Cross auxiliary hospital (see para. 12), and whenever a Local War Pensions Committee presents such cases for treatment this should be afforded for as long a period as may be required so far as available resources permit.

4. In order that Local Committees may be able to make themselves fully acquainted with the needs of men whom it is proposed to invalid, the fullest facilities should be given to duly accredited representatives of these Committees appointed as "Hospital Visitors" to visit and confer with the hospital authorities, or with the medical authorities of the command dépôt, or other unit in the case of a man not in hospital, and the man concerned.

In addition to treatment, an appropriate course of technical training may for many of the cases be desirable. The provision of the means for such training rests with the Ministry of Pensions, and full information bearing upon such matters should be placed at the disposal of the hospital visitor, and the officers i/c hospitals should assist with advice or in any way that lies within their power.

5. As soon as the soldier has been approved for invaliding from the army, the officer i/c hospital, or in the case of a man not in hospital, the president of the travelling or invaliding medical board, will forward to the Secretary of the Local Committee of the district in which the man proposes to reside a card (A.F. W. 3555), giving full particulars with regard to the man, his disability, and of the treatment recommended for him. If no treatment is recommended, the fact should be stated on the card, but in any case a card will be sent, as this notification is necessary to enable the Local Committee to visit the man immediately on discharge.

Where treatment is recommended at a military hospital or at a V.A.D. or Red Cross hospital the card will be sent to the officer i/c the hospital in which it is recommended that the man should receive treatment, and the officer of that hospital will, if the treatment can be given there, return it to the Committee with a note on it when the treatment is completed.

Officers i/c hospitals, or presidents of travelling or invaliding medical boards, as the case may be, will distinguish on A.F. W. 3555 between (a) cases which require out-patient treatment at a military orthopaedic hospital, and (b) those which can be dealt with satisfactorily at a general hospital, military or civil.

Orthopaedic Hospitals.

(a) Cases falling under one or more of the following headings will be certified for treatment at a military orthopaedic hospital, their cards (A.F. W. 3555) being marked "Orthopaedic A":—

- (i) Disabilities of hands and feet.
- (ii) Bony or fibrous ankylosis of joints requiring operative or manipulative treatment in order to restore functions, or flail-joints requiring operative or mechanical fixation.
- (iii) Mal-united or un-united fractures or any type of functional disability following fracture.
- (iv) Stiff or useless limbs the result of injuries to nerves, especially cases where nerve suturing having failed tendon transplantation is indicated.
- (v) Various contractions of the extremities due to scar tissue.
- (vi) Derangements of the knee due to injury of the semilunars or following upon operations for this condition.

(b) Other orthopaedic cases requiring out-patient treatment will be marked on A.F. W. 3555 "Orthopaedic B" for treatment at a civil or military general hospital.

B. Treatment of Post-Discharge Cases.

6. Men who have been discharged from the service on medical grounds, and are subsequently found to be in need

of further treatment, may be given such further treatment on the lines indicated in para. 3.

Such cases may also, if considered necessary, receive in-patient treatment at a military hospital, if facilities are available, under the conditions laid down in A.C.I. 210 of 1917.

In order, however, to keep within reasonable limits the cases which may receive out- or in-patient treatment in accordance with this para., it has been decided to limit the cases which may thus be sent for treatment to cases of wounds or injury sustained during military service.

7. All post-discharge cases will, in the first instance, apply to the Local War Pensions Committee, who will refer the man (unless the case is immediate and urgent, or the character of the case is obvious) to a medical referee, who will determine whether the case is one of wound or injury sustained during military service, and, if he so finds, the man will be referred to a military hospital for examination.

8. The officer i/c the military hospital to which the man is sent under the provisions of the preceding para., will cause the man to be examined and will enter full particulars on the treatment card (A.F. W. 3555), which he will immediately forward to the Local Committee by whom the man was referred. He will also give one copy of the completed card to the man examined.

A.F. W. 3555 will be clearly endorsed in red ink with the words "Post-Discharge Case" at the top of Part I by the medical officer examining the man, who will also record his opinion on the form as to:

- (a) The nature of the man's complaint;
- (b) Whether treatment can be given in the hospital where the man was examined, and if not, to what hospital he should be referred;
- (c) If in- or out-patient treatment should be given;
- (d) The probable period of treatment, so far as can be foreseen.

This treatment card will be accepted by the Local War Pensions Committee as authority for making the necessary arrangements for the man's further treatment, which treatment should, if practicable, be given at the military hospital where the man was examined.

C. General Arrangements for Securing Treatment on or after Discharge.

9. It will be necessary to give the widest possible publicity to the facilities thus to be afforded to discharged soldiers, and to this end a poster has been issued by the Ministry of Pensions, copies of which should be displayed in a prominent position in each ward and in any other convenient and conspicuous position in the hospital, command dépôt, or camp.

The lists of Local Committees therein referred to will be supplied by the Ministry of Pensions, Westminster House, Millbank, S.W. 1.

Supplies of the card should be demanded in the usual manner. Further copies of the poster will be supplied on application to the Ministry of Pensions.

10. The D.D.M.S. of the Command will furnish to the Ministry of Pensions and to the Local Committee, lists of the military hospitals which will serve the various districts concerned; also a list of special hospitals in the command, stating the nature of the special treatment afforded in each. The D.D.M.S. will also afford any further information and advice to any Local Committee or Joint (Disablement) Committee within the area of the command.

11. The details connected with the attendance of men for further treatment will be arranged locally by officers i/c hospitals in consultation with the secretaries of the Local Committees.

12. Payment for the treatment of discharged soldiers as out-patients at V.A.D. or Red Cross auxiliary hospitals will be made by the Ministry of Pensions to the hospitals concerned at a rate decided upon by the Ministry of Pensions and the Committee of the British Red Cross Society and the Order of St. John. No payment should be made from Army Funds in connexion with the hospital treatment either as in-patients or out-patients of pensioners at V.A.D. or Red Cross auxiliary hospitals.

THE Italian Sero-vaccino-therapeutic Institute founded by Professor Ivo Bandi was officially opened at Naples on September 29th. It is intended to be a centre of biological research, especially in connexion with colonial hygiene. Professor Bandi has founded bursaries for students attached to a chair of colonial hygiene, and others will be created with the object of attracting foreign students of bacteriology.

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

THE DEVELOPMENT OF COAL GAS AS A
MOTOR FUEL.

NECESSITY being ever the mother of invention, since last I wrote in these pages on the subject of the utilization of coal gas as an alternative motor fuel to spirits, which are becoming available in ever diminishing quantities, matters have marched rapidly as regards the evolution, and even the production, of new devices for containing the one form of motor fuel in these islands which is not experimental and the increasing use of which is all to the gain of the Ministry of Munitions, in that the more coal gas produced the greater the proportion of the necessary residuary products for the manufacture of high explosives, and so on.

We are now arrived at the fourth licensing term since the introduction of petrol rationing. Happily, the work medical men do is regarded as of national importance. Therefore there is no question that those who hold licences will secure renewals of sorts. The new order, which comes into force on November 1st, specifically permits the use of petrol or petrol substitute "in the conveyance of a duly qualified medical practitioner or veterinary surgeon while it is being used by him for the purposes of his profession." But it is equally plain that the amount which it has been possible to allot medical men in the past has been wholly inadequate. It is scarcely less plain that the amount it will be possible to allot in the future will be still less adequate. This is to be accounted for under many heads, perhaps the chief of which are that great increases have been made in the provision of agricultural motor machinery over what was anticipated earlier in the year, with the result that there are at least 6,000 tractors in this country to-day and there can scarcely be fewer than 15,000 available from the early part of next year onwards. Hence, a vast extra demand for motor fuel will arise under this head. It is of an essential nature, as brought out by the Premier last week in an address to farmers in regard to the urgency for their producing an unprecedented amount of cereals in these islands next year. The second head is the expansion of the Allied air services, including not merely the British, but the very ambitious American programme also, which is due to be launched any time from a couple of months onwards. Every gallon of motor fuel to operate it will have to be sea-borne to France and will therefore make additional demands on the strictly limited though, fortunately, increasing amount of tank-vessel tonnage available.

AT LEAST AN AUXILIARY FUEL FOR MEDICAL MEN.

It being certain that, under the new licensing scheme, the average medical man will not be able to obtain sufficient motor spirit for his needs, and the nature of the bulk of his work consisting of runs each of relatively brief distance, he may be classed as among the sections of motor owners for whom the use of coal gas as an alternative fuel is admirably suited, and almost imperative. Moreover, the approach of winter is a signal, on the one hand, for less economical consumption by reason of cold and windy weather, and on the other for experiencing greater difficulty in starting engines on motor spirits owing to their failing to vaporize satisfactorily while the carburettor intake pipes are chilled and the cylinders are cold. When coal gas is used as an alternative fuel to take out petrol supplies it is found that, in practice, the engine will start up much more readily in cold condition on coal gas than on motor spirit, because, with the former, the explosive mixture is ready made.

THE PROBLEM OF OBTAINING SUPPLIES.

The Government having tardily announced the appointment of various men to offices alike concerned with economizing the use of motor spirits and with encouraging the development of coal gas, the individual medical man may take it for granted that in a short time the present problem of inadequate supplies of gas for motor traction purposes will have been solved. At the moment, however, despite the exhortations of the Ministry of Munitions that gas should be used for power plant to increase the production of by-products for the making of high

explosives and other munitions of war, the Sheffield Gas Company, to take an instance, is unable to undertake any measures to supply gas for motor traction owing to a shortage of labour, which is the sole trouble, for this particular company has both the plant and the coal; therefore, in that centre some enthusiastic pioneers in the use of coal gas for motor traction are unable to get their requirements. It may, however, be taken for granted that this problem of providing the necessary labour for the manufacture of gas will be readily solved, not merely in one locality, but in all localities where it may occur at present.

Nor should the medical man, as an individual, be discouraged from the use of coal gas for traction purposes by the present problem of guaranteeing users the provision of supply stations at the necessarily frequent intervals. In face of the fact that the range of gas fuel contained in fabric bags at atmospheric pressure is rarely more than from twelve to twenty miles per charge, and, in steel cylinders under compression, is fifty miles per charge, it will be appreciated that many medical men can make most of their journeys quite safely without risk of being stranded between supply stations. Besides, inasmuch as a medical man is assured of a certain proportion of petrol supplies being allowed during the next six months, he could always ensure against being stranded on the road by carrying petrol in his tank, on which he could fall back in the event of the supplies in his gas container becoming exhausted *en route*. Such petrol as he is licensed to buy could be kept, besides, in reserve for such long distance journeys as he may be called on to make occasionally.

Not quite so simple a problem at the moment, however, is the matter of his obtaining supplies anywhere he may chance to find himself. With characteristic enterprise, the Manchester Gas Department, which went full early into this matter, has advocated a standard set of filling arrangements throughout the district. This may be taken as the basis for a scheme which should obtain throughout the country. Indeed, the Government is to blame in not having anticipated the Manchester Gas Corporation in having both devised and determined the standard methods and systems of distribution.

A MODEL DISTRIBUTION SCHEME.

The Manchester scheme is so admirable that I give a summary of it here.

Meters.—Automatic type, 100-light size, fitted with special quick opening and instantaneous closing valve, the valve having a gas way equal in area to a 2-in. pipe, to be operated by a metal token (not coin size), each token representing 100 cubic feet of gas.

Fittings.—The outlet of meters to be fitted with flanges for 2-in. iron pipe, into which a 2-in. iron full-way plug cock is fitted. Each installation to be supplied with a 20-ft. length of 2-in. rubber packed flexible metallic tubing, fitted each end with a 2-in. gas thread female flat-face union.

Position of Meters.—Meters to be fixed at garages or similar establishments on all main roads, and to be fixed free of charge to tenant. The tenant to be allowed a rebate of 10 per cent. on the face value of all tokens collected from the meter fixed on his premises as a remuneration for rent and any trouble he may be caused in connecting up to vehicles, although it must be made clear that the responsibility for connecting up rests entirely with the driver of the vehicle.

Price of Gas.—4d (fourpence) per 100 cubic ft.

Tokens.—Tokens (each being value for 100 cubic ft.) may be purchased at gas offices or other convenient places at 4d. (fourpence) each for cash, and must be stamped with the name and address of the gas undertaking issuing them.

Interchange of Tokens.—Arrangements are to be made whereby foreign tokens collected from a meter may be returned to the issuing office, who should give either a credit note or cash for the face value of such tokens, or tokens of similar value, to the collecting company.

Working Instructions.—An enamelled plate to be fixed in a prominent position close to each meter, lettered somewhat as follows:

Instructions.

1. Connect up union end of flexible tube to inlet pipe of gas container, taking care that all joints are gas-tight.
2. If the vehicle is fitted with a main cock in the inlet pipe to gas container, see that it is open. See that the engine control cock is closed. See that main cock fitted to outlet of meter is closed.
3. Insert one or more tokens and turn handle in the direction of the arrow.
4. When gas container is filled:

Close the main cock on meter.

Close main cock on inlet of gas container.

Disconnect flexible tubing.

Advertising.—The situation of these (meters, and the hours the establishment is open and the meter available for a supply of gas, to be stated by the gas undertakings joining in this scheme.

The whole of the information thus obtained to be issued in a booklet and distributed free of charge to owners of motor vehicles on application.

Enamelled plates to be provided and fixed in a prominent position on the premises in which meters have been fixed, indicating that motor vehicles may be charged up with coal gas.

Standard Pipe Fittings for Motor Vehicles.—If 2 in. gas thread is adopted as the standard fitting on the flexible tube, the gas undertakings joining in this scheme should advise all vehicle owners (and assist if necessary) to fit up their vehicles with the inlet pipe to gas container fitted with a similar size thread—namely, 2 in. gas. A drawing of a vehicle fitted up in the way advised should be made and a line block made from it. This block should be reproduced in the booklet referred to, together with a copy of the working instructions and advice as to how the best results from coal gas may be obtained.

OCCASIONAL EXPLOITATION OF THE USER NEEDS PROHIBITING.

That is a sound and simple working basis. The first point that strikes one about it is that Manchester does not mean to utilize this new market for fuel as a means of profiteering by exploiting motor users in their extremity. The price of gas is fixed at 3s. 4d. per 1,000 cubic feet, which is practically equivalent to petrol at 10d. per gallon, representing an enormous economy, and being, therefore, of direct interest to the average medical man.

Unfortunately, the integrity of the Manchester Gas Department, and those at Windsor and many other districts, is not at present universal. Thus there are gas companies in London—which is greatly backward in this matter—which are seizing the opportunity to charge motorists *more for the act of filling* their containers at mere atmospheric pressure than they are for the actual gas put into them. For example, while the price of gas in some western districts is 3s. 4d. per 1,000 cubic feet, a 200 foot container which should be filled at atmospheric pressure for a charge of 8d. is, nevertheless, charged at a cost of 2s. 2d., representing an extortionate demand of no less than 1s. 6d. for the mere act of filling.

If we were dealing with gas supplied to steel cylinders under compression the matter might be different. As it is, there is no excuse for this sort of thing, particularly inasmuch as all gas so sold is additional to the gas companies' ordinary profit-making scheme, in that its dead charges for plant, rates, rents, taxes, and so forth do not increase, but only those for the bare raw materials and for labour. Inasmuch, too, as the additional residuary products suitable for the making of munitions of war are also saleable to the Government on most profitable terms, and as such extra supplies could not be available for sale at profit unless motorists come to take the extra supply of gas made at the given factory, there is no excuse for allowing London gas companies to act as Manchester ones

do not. Lastly, all gas companies' charges are arrived at on a profit-paying basis, and it does not matter in the least to the individual gas maker what use is made of his commodity after he has produced it—that is say, whether it is used for lighting, for cooking, for power plant in a factory, or for motor traction on the road.

We may with reasonable confidence, therefore, look to the Government promptly to take measures, both in the interests of the prosecution of this war and in the interest of those in need of medical attention, as a single and over-present section of the community, to ensure that the gas

companies shall not hold up to ransom those patriotic motorists of all classes, from lorry to limousine users, who have had, or who will have, their vehicles adapted to run on town gas, with the dual aim of relieving the demands on motor spirit and of enabling them each to get through more of their given national work in the course of every twenty-four hours. The medical man without the freest possible facilities for getting about is perforce restricted in the amount of work he can do in a day.

FIG. 1.—B.S.A. landaulette, belonging to the Evesham Motor Engineering Co.

POINTS FOR AND AGAINST THE VARIOUS GAS HOLDERS AVAILABLE.

The medical man's difficulty in the matter of dealing with gas as a motor fuel is its bulk. Containers at atmospheric pressure and fashioned of fabric are ideal for his purpose from every point of view save as regards volume. The fact that an individual container will hold a charge barely sufficient for more than twelve to twenty miles range does not matter to him particularly, because he has his petrol rations to fall back on for long journeys, and because, doubtless at no distant date, the Government will order the gas companies to approve and cause to be installed certain apparatus, much on the Manchester scheme, which could be set up even at the individual's house on extremely moderate terms, so that the

cost could be saved by the individual user on a month's fuel bill at the outside. But whereas omnibuses or cabs kept in large, specially built motor houses, or the average utility vehicle run by big firms, also provided with specially built accommodation, could carry a flexible fabric gas container on its roof, the entrance to the average medical man's motor house

FIG. 2.—Gas container (280 cubic feet) on two-wheel Cox trailer coupled to car. A flexible coupling leads from gas bag to carburettor.

is too shallow to admit a vehicle of such depth as, say, a limousine, a landaulette, or an ordinary touring collapsible hood kept up permanently with an inflated gas bag on the top of it. The ingenuity of designers and manufacturers may, perhaps, eventually overcome this objection.

But inasmuch as the average medical man has no call to motor either fast or far on each journey there is no reason why he should not with advantage employ the trailer scheme, such as has been devised and used successfully even on such heavy vehicles as those carrying four-ton loads, for which it will suffice for a twenty miles run per charge. As applied to the private motor vehicle, such

devices as Cox's gas trailer of 200 cubic feet capacity, or Barton's, are well worth the consideration of the average medical man, particularly if he has occasionally to make longer journeys than ordinary, and therefore to run on his petrol rations instead of gas. Then the trailer can be readily detached, and the car is available for use in normal condition.

The disadvantage of gas bags that can be contained in, say, the back of the car, is that their capacity is too limited; also on occasion the medical man has need of the full seating capacity of his vehicle. True, an alternative scheme to this has been evolved by Mr. F. A. Wilkinson of Hatfield, Herts, which is akin to two large square flexible trunks carried on the grid at the back of the car without undue overhang, and giving six miles range on a single charge. Such a device is also readily detachable when the medical man is running on an alternative fuel.

GAS UNDER COMPRESSION.

Assuming that the medical man can obtain supplies of one or another of the many devices employing metal cylinders for containing gas under compression, he has to consider various points before deciding to adopt such apparatus. The great advantages of compactness and of giving much greater vehicle range for each charge—say, up to fifty miles, against twenty on gas at atmospheric pressure only—is offset, first, by the problem of weight. A set of cylinders rarely weighs less than 6 cwt., while the lighter single cylinder scales something in the neighbourhood of 112 lb. That becomes an important item in these days of constantly deteriorating road surfaces, putting additional strain on springs, which are generally extremely hard to obtain as spares in the event of a spring breaking. Secondly, a certain amount of cost must obviously attach to supplying cylinders that take gas under high compression, whereas the filling of a collapsible fabric bag at mere atmospheric pressure is a matter involving no cost.

Nevertheless, a wide variety of steel gas cylinder devices has been forthcoming, one of them even employing the one-wheel auto trailer scheme carrying a nest of five cylinders. Most gas cylinders, however, are carried on the vehicle, as for instance the triple cylinder Pulham scheme introduced by the Marine Garage of Bexhill-on-Sea, and containing about 300 cubic feet of gas for each charge at a pressure of 150 lb. per square inch, or, approximately, 10 atmospheres, and giving a range of about twenty three miles for a weight of 650 to 675 lb.

Against this the advantages of the collapsible fabric gas holder at atmospheric pressure of 14.7 lb. per square inch include the fact that there is no weight whatever. In this connexion the following summary of facts in regard to gas holders has been drawn up by Mr. Edmund Dangerfield's organs, the *Commercial Motor* and the *Motor*, which have done most of the spade work in compelling the authorities to give attention to the very important proposition of the use of coal gas as an alternative fuel.

Gas-holder Capacities.

Type of Holder and Size.	Cubic Capacity at Atmospheric Pressure, 14.7 lb. per sq. in.	Capacity.		
		At 200 lb. Pressure above Atmosphere.	At 500 lb. Pressure above Atmosphere.	At 1,000 lb. Pressure above Atmosphere.
Flexible holder— 12 ft. x 5 ft. x 5 ft. ...	300	—	—	—
Railway cylinders— 5 ft. 6 in. x 1 ft. 8 in.	12.2	170	—	—
CO ₂ cylinders— 4 ft. 2 in. x 5 in. ... Special high pressure cylinders.	0.6	8.4	21	42

Flexible holders are obtainable in all sizes.

Railway cylinders are obtainable in sizes from 3 ft. 6 in. up to 9 ft. in length x 20 in. diameter; also 4 ft. 6 in. x 2 ft.; 6 ft. 4 in. x 2 ft.; 4 ft. 6 in. x 18 in., and 10 ft. 3 in. x 18 in.

CO₂ cylinders are obtainable in sizes from 4 ft. to 5 ft. x 5 in.

Standard gas filling connexions recommended:

Meter: 100-light automatic type.

Meter fittings: Meter outlet with flanges for 2 in. iron pipe, with 2 in. iron full-way stopcock. Installation to be supplied with 20 ft. length of 2 in. rubber packed metallic tubing fitted at each end with a 2 in. gas thread female flat-face union.

Car: Gas container to have a main cock on the inlet male union to fit end of tubing from meter installation.

LENGTH OF WEARING LIFE OF APPARATUS.

A not unimportant point in connexion with the fitting of apparatus of this sort is the question of its wearing life. Obviously, the life of metal cylinders is long. As far as I am aware, none has yet been known to wear out, though small parts, such as valves and so forth, may need renewal from time to time and are easily replaceable at a moderate cost. The railway type of cylinder, is of course, no experiment.

Until the Ministry of Munitions releases the metals and materials necessary for real progress in the matter of supplying coal gas under compression, however, it will be difficult to move rapidly or extensively in this particular direction, especially since manufacturers are not eager to spend time and money on experiments which cannot yet be followed up by quantity production of the article evolved. Doubtless, however, this unsatisfactory condition of affairs will be altered now that the Government is setting to work.

An alternative scheme is to attempt something in the nature of gas compression in non-metallic fabric containers, such as that which Messrs. Wood-Milne, Ltd., are endeavouring to produce to withstand high internal pressure.

Much, however, might be done in the way of using discarded gas holders from railway coaches, each vessel with about 12 cubic feet capacity, capable of being charged up to 14 volumes of gas.

In regard to fabric containers for holding gas at atmospheric pressure, one has been in service for twelve months on the top of a single decker omnibus which has run more than 20,000 miles on coal gas; it is found to show little signs of wear to-day. Indeed, it seems to be agreed that, in regard to this class of apparatus, a generous maximum is to put depreciation at one-tenth of a penny a mile run, with the largest sorts, and about half that for passenger car types. If the apparatus is carried on the top of a vehicle, as is not likely in the case of an ordinary doctor's car for reasons previously specified, care must be taken in regard to driving lest overhanging branches or other projecting obstacles cause a ripping of the fabric of the holder. Even so, doubtless the individual when taking to the use of a gas holder can arrange with his insurance company that his car policy will cover anything occurring to any such attachment. In any case, he could insure against it for a purely nominal sum.

A PRACTICAL MAKESHIFT.

Flexible holders cost from £10 upwards, and are so light that they can be easily supported.

Admittedly, the atmospheric pressure scheme is neither more nor less than a war time makeshift; but that is all the medical man is asking for. His case is not that, say, of a commercial motor owner using gas, which may become a permanent form of fuel for such purposes.

After the war the market will be flooded with a large number of motor spirits, while the sudden cessation of the enormous demands for campaign purposes, with the continual increase in the building of tank vessels, will certainly ensure plenty of liquid fuel being available for motoring in this country, particularly because the present situation has given a great impetus to steam wagons operating with coal fuel, and because coal gas will probably remain a very favourite form of motor fuel for commercial motor vehicles on grounds of economy alone, and will doubtless be introduced within a season or so, at the outside, for agricultural motoring.

Obviously, the atmospheric pressure scheme is the best for the medical man, not only because metal containers for holding gas under pressure are not to be obtained in unlimited numbers, but also because the necessary apparatus for compressing the gas is not generally available. The medical man's point of view is that he must do something at once, and here is an available and non-experimental alternative, as instance the report issued last August by the British Commercial Gas Association, representing the

leading gas companies of the United Kingdom, which gives data on the subject of the utilization of coal gas for traction purposes. A copy of the report is obtainable from the Association at 47, Victoria Street, London, S.W.1.

Even when coal gas costs as much as 4s. per 1,000 cubic feet, it is equal to petrol at 1s. a gallon only. In England and Scotland coal gas is being used, particularly for omnibus and char-a-banc services, with thoroughly satisfactory results, and nearly always at merely atmospheric pressure, as instance the services operating at Edinburgh, Birmingham, Bristol, Bournemouth, and Eastbourne, and the rapid increase in the numbers of utility motor vehicles on the same scheme in Manchester and elsewhere.

Inasmuch as progress is being made so extremely rapidly that an increasingly large number of firms all over the country are laying themselves out specially to fit cars to run on town gas, the individual medical man may be recommended to read the *Motor*, which publishes a list, brought up to date weekly, of the various firms throughout the country that manufacture gas holders or which are laying themselves out for fitting the necessary, simple adaptor apparatus to individual cars.

Coal gas is clean in use, it needs no vaporization, the fuel control need call for no alteration; no carbon deposit is left; and the power obtainable is at least 85 per cent. of the efficiency of the best petrol.

[We are indebted to the *Commercial Motor* for the use of the two illustrations.]

PERMITS FOR THE USE OF PURE WHEATEN FLOUR FOR INVALIDS.

The following memorandum has been issued by the Ministry of Food, after consultation with the War Bread Medical Subcommittee:

Memorandum.

Since some misunderstanding appears to exist as to the granting of permits to use white flour, it seems advisable to indicate the procedure adopted in dealing with applications. These are considered in the first instance by the Scientific Adviser to the Food Controller acting under the guidance of the War Bread Medical Subcommittee of the Royal Society. After this first sifting of applications doubtful cases are referred to certain members of the subcommittee, who have agreed to act as referees, or they are laid before the whole subcommittee. It should be understood that applications are becoming so numerous and the necessity for economizing wheat so imperative, that it is not possible to accede to all the requests sent in. The committee is of opinion that in many cases no substantial grounds exist for the applications, which appear to be made merely to satisfy some whim of the patient and not because the Government regulation flour has been found to be deleterious. Speaking generally, it may be said that unless some affection of the digestive organs is present which, in the opinion of the War Bread Medical Subcommittee justifies the use of pure wheaten flour, an application cannot be granted. Thus, for instance:

1. *Acute affections of the stomach* (acute gastric catarrh, ulcer in its acute stages, etc.). In these cases the use of any form of bread whilst the disease is at its height is probably inadmissible. During the convalescent stages the prescription of pure wheaten flour for a limited period may be permissible if rusks and breakfast biscuits or ordinary bread boiled and sieved, or bread jelly, do not meet the case.

2. *Chronic affections of the stomach.* In chronic functional disorders of the stomach (which make up the majority of cases of chronic dyspepsia) the use of pure wheaten flour can rarely be allowed, for the reason that such cases are so numerous and so protracted in their course that it would be impossible to meet demand without seriously depleting the wheat supply of the rest of the population. The use of the present bread, well toasted and thoroughly chewed, or of biscuits and rusks, should be recommended. In chronic organic disease of the stomach (carcinoma and chronic ulcer) white flour may sometimes be advisable if the patient is able to take bread at all.

3. *Acute affections of the intestine* (acute diarrhoea, enteritis, colitis, ulcerative conditions, etc.). In these

cases the same remark applies as in acute affections of the stomach.

4. *Chronic intestinal affections* (chronic diarrhoea, chronic colitis, malignant disease, etc.). In some of these the use of white flour may be desirable; but evidence would be required to show that ordinary bread, toasted and thoroughly chewed, and the use of other measures, have failed to relieve the symptoms.

5. Cases of disease of the nervous, circulatory, or respiratory systems, or of the urinary organs or skin, or such general conditions as anaemia and diabetes, can rarely be considered suitable for grants.

6. As regards tuberculosis, there is no evidence that the present bread is injurious. Inquiries have been made from the principal sanatoriums for the treatment of this disease, and in the great majority of cases the medical superintendents support the above opinion. No institution for the treatment of this disease is receiving grants of pure wheaten flour.

To sum up, there are very few conditions, in the opinion of the War Bread Medical Subcommittee, in which the use of pure wheaten flour is essential.

The subcommittee is well aware of the difficult position in which the medical practitioners are placed; but it is necessary to conserve the wheat supplies of the country, and every means of doing this must be adopted, and if need be enforced. Refusal to give a permit does not imply that the medical certificate has been disregarded, but merely that the need of other applicants appeared to be more urgent. Above all, it is important that no discrimination be made between rich and poor in recommending these grants. Nothing is easier to arouse or more difficult to allay than a suspicion that the poor are denied what the rich find no difficulty in obtaining.

Under war conditions, when variety in foods is limited, the bread made from Government regulation flour is probably a more wholesome article of diet than that made from fine wheaten flour in pre-war time. The flour contains more lime salts than fine wheaten flour, and presumably is therefore more suitable for growing children. It contains a greater variety of proteins, which it is important to have, especially if bread enters largely into the dietary. It contains more "germ," which adds to the proteins and increases the fat. It also contains more of the class of substances known as "vitamines," about which our knowledge is far from complete, but it is known that a deficiency of these profoundly impairs nutrition. The bread requires to be thoroughly masticated, but if chewed well, or eaten as toast which necessitates chewing, or, finally (in the case of invalids), if it be used as indicated in paragraph 1, there are very few people with whom it could disagree.

The twenty-sixth meeting of the Congress of the Italian Society of Internal Medicine will be devoted to diseases among troops—icterus, malaria, cardiac affections, renal diseases and tuberculosis. It is to be held at the end of October in some city within the war zone, the name of which, together with the exact date of meeting, will be published later. Professor Luigi Lucatello, director of the medical clinic at Padua, is president of the organizing committee.

The total number of medical students in Switzerland in the summer semester of 1917 was 1,823. These were distributed in the five universities as follows: Bâle 227, including 13 Swiss women and 48 foreigners, of whom 2 were women; Berne 407, including 14 Swiss women and 168 foreigners, of whom 29 were women; Geneva 488, including 17 Swiss women and 334 foreigners, of whom 84 were women; Lausanne 208, among whom were 11 Swiss women and 92 foreigners, of whom 20 were women; Zürich 493, including 52 Swiss women and 177 foreigners, of whom 40 were women.

It was stated recently on the authority of the Federal chemist of Kansas that court plaster full of tetanus bacilli was being sold throughout the State. This report led to the arrest of five Germans, and samples of the plaster were submitted to the United States Department of Justice for examination. It is now officially announced that the Director of the Hygiene Laboratory of the United States Public Health Service has reported that among thirteen specimens of plaster purchased in the ordinary way in Washington and one from the Ohio Department of Health two contained tetanus bacilli. He states that there is no reason to believe that the contamination was intentional.

British Medical Journal.

SATURDAY, OCTOBER 20TH, 1917.

THE FOOD POSITION TO-DAY.

THE Food Controller and his lieutenants have recently issued several fresh appeals for the practice of food economy. Lord Rhondda, addressing the Food Control Committees, states that "the harvests of the world will not meet the requirements of ourselves and our allies during the next twelve months unless our present rate of consumption is materially reduced," and he adds that the need for the strictest economy is intensified by the steps which the Government have taken to reduce the price of essential foodstuffs. He asks the Food Control Committees to appoint Economy Committees for the prosecution of the food saving campaign, because unless the plain facts can be brought home promptly to every household the coming winter will be a time of the gravest anxiety. There is, he says, no alternative between a rigid economy voluntarily effected and a compulsory system of rationing.

The world shortage of food affects both cereals and meat, including bacon, as well as many other food commodities. It is due to two causes. The first is the poor harvests in certain countries, which have diminished the world stock, not only of wheat, but of other cereals generally used for the feeding of horses and the fattening of stock and pigs, so that it will not be economical to keep, or at least to "finish off," so large a head of food animals. The second cause is shortage of tonnage, produced partly by sinkings and partly by the diversion of much shipping to carry raw material to munition factories in this and other allied countries, and supplies of all sorts to the British armies in France, the Mediterranean, and Mesopotamia.

A comparison of the weight of bread allowed in countries rationed compulsorily or voluntarily shows that the differences are not very great, whether the nation be belligerent or neutral. Expressed in grams, the weight is: In Germany 280, Austria 280, Switzerland 250, Holland 254, Denmark 315, Sweden 260, France and Italy 250, Great Britain 259. The exceptions among belligerent countries are Bulgaria and Turkey; in the former the weight of bread allowed daily is said to be as high as 500 grams and in Turkey as low as 160, but the potato is not much used in Bulgaria, and probably more rice is consumed by the Turks than by other nations of Europe.

The Paris Academy of Medicine received on October 2nd the report of a committee on the bread now actually consumed in France, and adopted a number of resolutions. There is a suspicion that the bread sometimes supplied by bakers is injurious because the grain is not properly cleaned before grinding, and one of the resolutions of the Academy was directed to remedy this defect. Reason was found also to think that the bread was sometimes injurious because it had undergone an acid fermentation, and another resolution of the Academy suggested that lime water should be used in making bread, the majority of the Academy considering that this could have no evil effect on health. In view of the shortage of cereals the Academy recommended the more general use of rice as an article of food in France, and advised that a proportion of rice, barley, rye,

buckwheat, or maize flours should be used in the manufacture of bread.

The comparison of the amounts of bread allowed is crude in so far as it takes no account of quality. The ration of potatoes is in Germany about 450 grams a day, in Austria 1,000, in Holland 3,000. In Great Britain potatoes have not been rationed; at present they are plentiful, and an appeal has been made to make as much use of potatoes and fresh vegetables as possible. The food value of three ounces of bread, an ordinary allowance at a mixed meal, is 222 calories; of six ounces of potatoes, an ordinary helping, 155 calories. Potato dishes are cheap, and can be substituted for bread in whole or in part at all meals. It is pointed out, too, that potatoes may not keep well this year, whereas cereals will. The difference in the amount of meat allowed in different nations was this summer very great. It is said that in Germany it had fallen to 250 grams a week and in Holland to 200. In this country the voluntary ration is 1,130 grams a week. In Austria and Italy there are two meatless days a week; in Bulgaria there are three, but the Bulgarian has always obtained a large part of the protein and fat in his diet from the sour milk lately so fashionable here. In Germany fat is rationed to 90 grams a week, in Austria to 120, and in Holland to 50. These are maximum amounts; there is no guarantee that they will be available; and there can be no doubt that for a long time fats have been very difficult to procure in Germany, even at very high prices. We have experience in this country of what may be called market deficiency, as, for instance, in sugar, the half-pound a week allowed by the Food Controller having been at times unobtainable.

In spite of the many fallacies in these comparative figures, they serve to justify the official statements made in this country as to a world shortage of food. Our only consolation is that, in spite of ruthless submarine frightfulness, we are better off than the German, who is at present boasting that he can produce four-fifths of what he consumes. It is thought probable that there will be a serious shortage of butchers' meat this winter, and there is already a shortage of bacon. The difficulty for the housekeeper and caterer is to provide a palatable, nutritious, and varied diet while observing the restrictions of the Food Controller, and not exceeding the expenditure permissible to the family or the individual. Probably the best way of meeting the meat difficulty is to institute meatless days. This policy, enforced in Austria and Italy, has been followed voluntarily in some London clubs. The most popular substitute is probably fish, but the only kinds having a high nutritive value and available in sufficient quantities at a fairly cheap price are mackerel and herring. Sprats, when they can be obtained, are the most nutritious of all fish. Recently Scotch salmon has been as cheap, when nutritive values are compared, or cheaper than cod, and frozen Canadian salmon certainly cheaper; if well chosen and allowed to thaw thoroughly before cooking (boiling or grilling), it is very good eating. The food value of salmon is, however, about half that of mutton (leg) for the same expenditure. Probably the best all-round substitute for meat on a meatless day is cheese, cooked or uncooked. "Cheese should be restored to its old place as a staple food for all classes" is a statement to be found in a pamphlet *Food and How to Save it*,¹ written by Dr. E. I. Spriggs and published by the Ministry of Food for the guidance of the perplexed

¹ His Majesty's Stationery Office, 1917. To be obtained through any bookseller, price 3d.

housekeeper. It explains very clearly the principles upon which the nutritive value and relative cost of foods may be calculated, and gives much practical advice, although, like all essays on the subject at a time when supplies are uncertain and prices unstable, some of the detailed conclusions do not quite fit existing conditions, for there have been important changes in the market supply, especially in respect to potatoes, since the author wrote his preface last July. Modern civilized man dislikes a monotonous diet, and a worker tired by physical or mental labour craves for variety. It is probably because it is easier for even an indifferent cook to achieve some degree of variety, if only by varying the kind of meat, that it has become so established a custom to serve meat in the houses of the well-to-do middle and industrial classes in England twice if not thrice a day. Dr. Spriggs does not disdain housekeeping and cooking details: he has a chapter on how to make up the controller's allowance most cheaply, and another on how the allowance may be made up by the well-to-do and those earning good wages. Both contain suggestions for daily diets, and a third chapter deals with weekly budgets for families with three different scales of expenditure, the cost ranging from 8s. 9d. to 14s. 5d. a head a week.

The position with regard to permits for the use of pure wheaten flour for invalids is very clearly defined in the official memorandum, published at page 524, addressed to medical men by the Ministry of Food after consultation with the War Bread Medical Subcommittee. It is a very uncompromising document, but the Ministry, while it admits the difficult position in which medical practitioners are placed, states that the necessity is so great that every means must be adopted, and, if need be, enforced, for conserving the wheat supplies of the country. The procedure followed on receipt of an application is detailed. It is first considered by the scientific adviser to the Food Controller, and doubtful cases are laid before the whole subcommittee or referred to certain members who have agreed to act as referees. The memorandum states that, speaking generally, unless some affection of the digestive organs exists which, in the opinion of the subcommittee, justifies the use of pure wheaten flour, an application will not be granted. Various affections of the digestive organs are examined *seriatim* in the memorandum and reference is made to certain chronic conditions, with the general result that the Ministry, on the advice of the War Bread Medical Subcommittee, expresses the opinion that there are few conditions in which the use of pure wheaten flour is essential. It desires it to be understood that refusal to give a permit does not imply that the medical certificate has been disregarded, but merely that the needs of other applicants appear to be more urgent. The position of individual medical practitioners in dealing with the individual patient is often very difficult, especially, perhaps, in the case of well-to-do patients, but it is essential that no distinction should be drawn between rich and poor. The memorandum will undoubtedly prove helpful to medical practitioners when difficulties arise, and for this reason we counsel the preservation of this number of the JOURNAL.

REINFECTION IN SYPHILIS.

THE old dictum "*omnis syphilitic always syphilitic*," which implied that syphilis could only be contracted once in a lifetime, no longer holds good, for second attacks of syphilis, or *reinfection*, have been recorded by many careful observers, including such eminent authorities as the late Sir Jonathan Hutchinson and

the late Mr. Berkeley Hill. In order to prove absolutely that a case is one of true reinfection it is necessary for the patient to show definite signs of two infections presenting the primary signs of syphilis followed by typical secondary symptoms in due course. Hutchinson observed two such cases; in one the patient had two attacks of primary and secondary syphilis with an interval of five years; in the other the patient is said to have had three attacks at intervals of fourteen and nine years. Berkeley Hill reported the case of a surgeon who acquired syphilis in the usual way, and eleven years later contracted a digital chancre which was followed by secondary symptoms. Mentberger collected 356 cases of alleged reinfection from the literature, and found that only 119 fulfilled the condition mentioned.

A diagnosis of reinfection founded merely on the apparent development of a second chancre is insufficient and open to several fallacies, such as the occurrence of a chancreiform gumma of the penis, and relapsing chancre, or chancre *redux*, which, it would appear, is more frequently observed after the modern arsenical treatment. Such sources of error should be easily avoided, for the gumma is not accompanied by inguinal adenitis, and the *redux* chancre is situated on the site of the original one. Since the treatment of syphilis by salvarsan and similar arsenical compounds has been in vogue numerous cases of reinfection have been recorded on the evidence of a second chancre only, and such cases have been adduced in support of the curative value of this treatment. In this connexion the series reported by Major C. F. White, in the paper printed at page 509, is of considerable interest. It will be noted that the conditions he requires to prove reinfection depend mainly upon laboratory diagnosis. The most remarkable point is the short interval of time between the original infection and the alleged reinfection. In the series of 28 cases this interval was less than a year in 18, six months or less in 6, and in one case three months only.

The question naturally arises whether these were instances of true reinfection or whether the lesions can be accounted for in some other way. It is conceivable that they were irritation reactions due to the presence of active spirochaetes within the body—that is to say, that the lesions were of internal and not external origin. Neisser, by experiments on apes, found that the internal organs were virulent when the skin had acquired a definite degree of immunity, and Levaditi states that the skin may be immune to external spirochaetes, but receptive to internal spirochaetes. Against this hypothesis it may be argued that intensive treatment with salvarsan will destroy all the spirochaetes in the body, and that a negative Wassermann reaction after such treatment is evidence in support of this. But this reaction may be negative in cases with obvious clinical signs of syphilis, and may change from negative to positive and vice versa independently of treatment. It may also be objected that if the lesions in question were irritation phenomena due to infection of the skin by internal spirochaetes the lesions produced a few months after the original infection would resemble those of secondary and not primary syphilis, since Finger and Landsteiner found that inoculation of patients in the tertiary stage of syphilis with virus from primary and secondary doses produced lesions of a tertiary nature, showing that these lesions do not depend on the quality of the virus but on the mode of reaction of the tissues. The problem of immunity in syphilis is complicated, and it is difficult to exclude all the sources of fallacy.

THE UNIVERSITIES DURING AND AFTER THE WAR.

THE address delivered at a memorial service for members of Manchester University who have fallen in the war, by Sir A. W. Ward, now Master of Peterhouse, Cambridge, formerly Principal of the Owens College and Vice-Chancellor of the University of Manchester, has been printed by the Manchester University Press.¹ It is largely concerned with the history of that university, but will repay perusal by those not directly connected with it. While speaking of the past, Sir A. W. Ward spoke also of the present, "some part of whose sacrifices and achievements," he said, "engraved for ever upon our hearts as they will some day be inscribed upon these walls, may, without presumptuousness or mere conventionality, be traced to the inspiring influences of our common academic life and its traditions. In return these very sacrifices and achievements are themselves also to be numbered among the more generous and enduring incentives to the exertions of the future." He interpreted the feelings of his audience when he further said that they desired to send a word to the graduates, teachers, and students, past and present, officers and employees of the university, a message of the pride taken in the thought that service such as theirs had been and is being rendered. The message, he said, was also addressed to those members of two learned professions—medicine and the Church—who wore the King's uniform in token of services rendered never more assiduously and unselfishly than during the present war. The physicians and surgeons, he continued, who form part of the medical faculty or hold its degrees, "have given evidence at the front, and in our military and naval hospital wards, abroad and at home, of a devotion unsurpassed even in the annals of their magnanimous profession." Speaking then particularly of women, he referred to the nurses abroad and at home, to the women doctors, of whom many had bravely rendered valuable service in Serbia, and more recently in Southern Russia, and to those women graduates who had undertaken temporary administrative work of various kinds. Nothing, he thought, proved better the wisdom of the decision that men and women should work together in the university than the way in which women students had proved themselves impressed by a sense of the duty resting upon all. After some words of consolation to those who by reason of age or infirmity were unable to do active war work, he went on to remind them that, with the help of the younger graduates, they must prepare for future changes. "You will not," he said, "and your sister universities will not, be able so to 'shape your old course in a country new' that you can without changes suit your system to the demands which new necessities, new developments, new possibilities bring with them." The more serious the changes the more careful, he said, must be the deliberation for which they would call, and he deprecated the too speedy adoption of piecemeal reforms when they involved more than the filling up of unmistakable gaps in a system of academical studies, or the removal of palpable obstacles to its legitimate expansion. These are wise words, and the principle they embody has an application beyond university policies.

CARDIAC DISORDERS DUE TO THE NEW POISONOUS GASES.

THE symptoms of gassing have been tabulated as respiratory, gastro-intestinal, and nervous, but there seems to be evidence for the recognition of other forms depending on the nature of the gaseous constituents. The better known gases employed in the war mainly contain chlorine and its

allies and act on the respiratory system, causing sudden and intense asphyxia with rapid death, acute asphyxia after an interval with only slight symptoms of poisoning, or a caustic tracheitis and bronchitis; the symptoms of the two latter groups have been recently studied by Colard and Spehl¹ who recommend free venesection and the continuous inhalation of oxygen conducted through a Wulff's bottle to the nasopharynx by means of a catheter passed through the nostrils. As late results of respiratory gassing pulmonary tuberculosis, empyema and pyopneumothorax may occur. There are other gases not yet completely analysed but containing cyanogen compounds, which though only recently introduced into warfare are known to cause industrial poisoning of a chronic form. Recently Professor L. Barker,² of the Johns Hopkins Hospital, has referred to a case of sudden but quite transient auricular fibrillation induced by the fumes of hydrogen sulphide. According to C. Fiessinger³ soldiers suffer from acute and severe symptoms due to poisoning of the medulla by these gases. After noticing a sweet smell the victims get burning in the throat, extreme weakness, frequent attacks of syncope especially on movement, extremely slow (25 to 30) but regular pulse, pallor, vomiting, vertigo, and a low blood pressure. The disorder lasts for a long time and necessitates rest in bed for many months. Treatment at the onset consists in immediate bleeding and injection of camphor. Subsequently the gastric symptoms may require bismuth. For the cardiac condition small doses of caffeine and strychnine are recommended, but digitalis, strophanthus and sparteine do harm, and, in spite of statements that it does good, adrenalin has been disappointing.

FIRING ON THE RED CROSS.

WE published last week a letter from a correspondent who was near the spot where the American surgeon was killed in a British hospital at a French seacoast village. He suggests that it was by accident that the bomb fell on the hospital, being intended for ammunition dumps, cement works, reinforcement camps, and training grounds, which he described, perhaps with a little poetic licence, as "cheek by jowl" with the hospitals. We are glad to give the German raider the benefit of the doubt, but in the article which our correspondent was criticizing reference was more particularly made to the bombing of advanced hospitals on the Western front, both of the British and the French armies. We shall be very glad to doubt these stories also, but the evidence for their truth is strong and seems to have been fully accepted by the French authorities. That the Germans have indulged in the sniping of stretcher-bearers has often been asserted, and the correspondents sent home last Sunday a very circumstantial story of the deliberate sniping after the battle on the previous Friday. Late in the afternoon British stretcher-bearers, who had been working all day under heavy fire, went forward to collect wounded who had been lying out. On the slopes of Passchendaele the enemy stretcher-bearers, were seen working too, and one body of 200 men came out, waving a Red Cross flag, with the stretcher-bearers and ambulances, and were left undisturbed by the British. "But," says the correspondent of the *Daily Telegraph*, "shots from the German snipers were still flying and our stretcher-bearers were hit. Three of them carrying one stretcher were killed, and an officer with them directing this work near Poelcapelle was fired with a flame of anger. He seized a Red Cross flag and made his way very quickly over the shell-holes towards the enemy's position, and, standing there, this officer of the R.A.M.C. shouted out a speech which rang high above the noise of the gun-fire and all the murmur of the battlefield. I do not know what he said, the exact words he shouted out in his fine

fury. But he cursed men so lost to all humanity that they would shoot the rescuers of the wounded. He cursed them as cruel beasts, worse than savages, and he raised his flag and pointed to it and then to the German stretcher-bearers beyond, and spoke other flaming things. Perhaps what he said was quite incoherent and wild. Perhaps no man who heard him could understand a word of what he said, but there in shell-holes, hidden from him in mud, were listening men, with loaded rifles, and they may have raised their heads to look at that single figure with the flag. They understood what he meant, his accusing figure was a message to them. After that there was no deliberate sniping of stretcher-bearers, though they still had to go through the shell-fire." It was a gallant act, and whatever excuse may be devised for the German snipers in this instance also, the story affords a vivid picture of the risks willingly taken by stretcher-bearers at the front, as well as by officers of the R.A.M.C.

PARAFFIN DRESSINGS.

PROFESSOR RUTHERFORD MORISON gives an account this week of the method he now follows in the treatment of wounds by means of the bismuth iodoform paraffin paste which he introduced last year. The results have been very satisfactory, not only in his own hands but in those of other surgeons, and his present paper is intended to draw attention to the technique which should be followed, as some failures have been due to faulty surgery. But the paper, taken along with others published in this issue, will probably raise in the mind of some readers the question as to the part played respectively by the paraffin, and the bismuth and iodoform dissolved in it. Bismuth is admittedly a poor antiseptic, and Beck's bismuth paste, which consists of 30 per cent. of bismuth oxycarbonate dissolved in soft paraffin, has been proved valuable in the treatment of chronic suppuration and sinuses; but as Mr. Rutherford Morison has remarked elsewhere, no satisfactory bacteriological explanation of its action has been offered. The general conclusion to be drawn from the paper by Drs. Helen Chambers and J. N. Goldsmith to which he refers seems to be that the bactericidal action of bipp results from the free iodine liberated by the oxidation of the iodoform by oxygen, and by the nitric acid formed by the hydrolysis of bismuth nitrate. In his paper published this week Professor Morison mentions the risk of iodoform and bismuth poisoning as a drawback to his method, although he says that since adopting the plan of smearing the surface of the wound and rubbing in the bipp, removing the excess, he has met with no trouble of the sort. The paste recommended by Captain Hey, on which a report by Captains Rendle Short, Arkle and King is published at p. 506, seems to give equally good results; they, however, follow the practice of excising the wound, which, we gather, Professor Rutherford Morison considers to be unnecessary. They state that by using the Hey paste they have been able with fair consistency to obtain healing within a fortnight of cases of compound fracture, even when complicated by joint injury. On the other hand, they say that the original pasting is not effective after three days, whereas Professor Morison leaves the dressing unchanged after the application of bipp for as long as three weeks, or longer, unless pain or constitutional disturbance indicates interference. The method may possibly, as Professor Morison anticipates, be improved, but obviously it is applicable as it is to severe wounds in civil life. In connexion with the use of an oily medium for applications to wounds it may be useful to recall the attention of surgeons to the paper (BRITISH MEDICAL JOURNAL, August 25th, 1917, p. 249) by Professor J. E. Sweet, of Philadelphia, relating his experiences in France with the oily solution of dichloramine-T devised by Drs. Dakin and Dunham for another purpose—namely, disinfection of the nasopharynx.

PRIMARY TUBERCULOSIS OF THE FAUCIAL TONSILS.

THE common belief that primary tuberculosis of the faucial tonsils is rare probably depends on the usual absence of signs and symptoms apart from the secondary infection of the cervical glands, and on the impossibility of recognizing it without the help of the microscope, and inoculation experiments. Dr. A. Philip Mitchell, in a paper on this subject in the *Journal of Pathology and Bacteriology*,¹ gives the results of examination of material obtained from surgical operations during six years of hospital practice, his investigations forming part of a study of tuberculosis of the cervical lymph nodes, reported on in the *BRITISH MEDICAL JOURNAL* of January 17th, 1914. This inquiry fell naturally into two divisions: the examination of tonsils removed from children affected by tuberculosis of the upper deep cervical glands, and the examination of hypertrophied tonsils removed from children with no clinical evidence of tuberculosis of the cervical lymph nodes, or other parts. Four points received particular attention: age of patient; source of material—that is, whether obtained during life or *post mortem*; clinical evidence of tuberculosis; and history of tuberculosis in other members of the household. By means of histological examination and animal inoculations Dr. Mitchell finds that primary tuberculosis of the tonsils, at least in Edinburgh, where, out of 406 samples of mixed milk collected from milk shops, 82 (20 per cent.) contained tubercle bacilli, is much more frequent than is usually held. Thus, out of 106 (100 children, 6 adults) operation cases of tuberculous cervical glands, 41, or 38 per cent., showed tonsillar tuberculosis, most often immediately under the surface mucosa, less frequently in relation to the deeper parts of the crypts or close to the capsule. In 80 out of the 106 cases the tonsillar lymphatic gland in the angle formed by the junction of the common facial and internal jugular veins under the posterior belly of the digastric muscle showed at operation evidence of the most advanced tuberculous change. The inoculation test was positive in 20 out of 92 cases, the bovine type being present in 16 and the human in 4. The reason why inoculation was less often positive than the microscopic test is that many of the guinea-pigs died from rapid septic infection before the tuberculous changes had time to develop. The size and shape of the tonsil do not show any special relation to tuberculous infection; in 51 cases the tonsils were small, submerged, and firm, in 27 cases large, and in 28 of medium size. Among a further series of 100 chronically hypertrophied tonsils without tuberculous cervical glands tuberculosis was found in nine. Dr. Mitchell's main conclusions may be put briefly as follows: Tuberculosis of the upper deep cervical glands develops from a primary focus in the tonsils much more often than is generally supposed, but the primary tonsillar infection can only be detected by the aid of the microscope and inoculation experiments. The lesions are principally found just under the surface epithelium and near the mouths of the lacunae; less often in the deeper portions. Hypertrophied tonsils may be the seat of primary tuberculosis, though rarely as compared with tonsils from cases of tuberculous cervical adenitis. In Scotland at any rate primary tuberculosis of the tonsils in children is attributable rather to the ingestion of tuberculous milk than to the inhalation of human tubercle bacilli; it is, therefore, essential in the present state of the milk supply that children's milk should be boiled. In all cases of tuberculous glands in the neck removal of the tonsils entire in their capsule is necessary. Lastly, bovine and human types of tubercle bacilli are present in the tonsillar crypts of a small percentage of children without demonstrable tuberculous lesions, either in the tonsils or elsewhere.

PROPHYLAXIS OF VENEREAL DISEASE IN THE AUSTRALASIAN FORCES.

THE report of the last annual general meeting of the Royal Prince Alfred Hospital, Sydney, of which a copy has reached us, is mainly given up to an interesting survey of the past year's work by the Chairman of the Board, Sir Thomas Anderson Stuart, M.D., who is professor of physiology, and Dean of the Faculty of Medicine in the University of Sydney. Discussing the work of the special departments, the chairman made pointed reference to the problem of venereal disease. After reference to the establishment of venereal clinics—in which matter the Alfred Hospital has served as a model for the establishment of similar clinics in three other Australian states, and in New Zealand—he proceeded: "I now come to an important aspect of this matter which has arisen out of our participation in the treatment of venereal diseases. I refer to a communication which I addressed to the Minister of Defence covering a report which was made to me by the Medical Superintendent, who had just returned from Egypt, where, as a major in the Medical Service, Expeditionary Force, he had been instrumental in carrying certain measures into effect with the most happy results. In consequence of this communication the Defence Department ultimately established similar arrangements at each of the camps in the different states. These measures I need not go into in detail here, but they might be shortly stated thus: What is called a prophylactic or preventive tent is established at the entrance of each camp. Certain measures are there taken, as men who have exposed themselves to infection return to their quarters, with the result that of a certain series of 2,000 cases reported upon, only three developed the diseases, while in another series in the first month after the system had been established, of 432 men who were attended to in the tent not one developed the disease, while of 35 men who developed the disease, not one had visited the tent. These results show how sinful it is on the part of authorities to neglect such cases, because the results show that the diseases are entirely amenable to preventive treatment. The cost of the measures is practically negligible. When we review these magnificent results there is every reason to expect that if these measures were only applied as completely in the civil community as in the military, the frequency of these diseases would be enormously diminished, and with continued strenuous application and effort they might be practically wiped out." By way of footnote to this extract it may be mentioned that we have received from the honorary secretary of the New Zealand Volunteer Sisterhood an account of what is about to be attempted, by means of "soldiers' medical clubs," to check the spread of venereal disease among soldiers of the New Zealand Expeditionary Force in the United Kingdom. It appears that the objects and policy of the clubs are approved and encouraged by the commandant of the force. The honorary medical adviser will give elementary instruction in sex hygiene and the general prophylaxis of venereal disease. In addition, prophylactic outfits will be supplied, together with explicit directions as to their use; and this we take to be the main reason for the establishment of these clubs.

A NEW ELECTRICAL STARTER FOR MOTOR-CAR ENGINES.

ELECTRICAL devices for starting motor-car engines by mechanical means may be classified, according to the method of applying the energy, into those that are friction driven and those that operate by the meshing of gears. Hitherto the mechanical engine starters made by the electrical firm of C. A. Vandervell, Warple Way, Acton, have started on the friction principle. A demonstration of a new model employing the gear principle, evolved by Mr. A. H. Midgeley, reveals sundry advantages for the new type, which is the outcome of lengthy tests. It is lighter,

cheaper, easier to fit, more efficient, and, as presented by the C. A. V. firm, more economical of current than their friction driven varieties. On the other hand, unless the design is carried out very carefully, it is easy for a device of this sort to manifest a series of faults. Consequently, interest centres as much on the features that are omitted from the C. A. V. scheme as on those that are embraced in it. The new machine has no chain to stretch, necessitating adjustment. There is no resistance switch, with its consequent possibility of burning out. There is nothing in the nature of an overrunning clutch. The features that are embodied in it include the fact that the starter motor is practically inaudible, and quite automatic when engaging the gear on the fly-wheel. It does not rely on speed to effect a proper engagement. It is only possible to apply the whole power of the motor when the gears are fully meshed. No damage can result from anything in the nature of backfires. The release of the pinion is automatic immediately the engine starts. No sort of spring is relied on for disengaging the gears. To keep them in mesh once the engine is running is impossible. The system is, in a sense, a combination of well-tried features. Thus the armature shaft of the starting motor can move endways as the result of magnetic influence acting against the pressure of a spring. At the end of the armature shaft there is a small pinion which is kept in mesh with the spur wheel on the periphery of the engine fly-wheel. The longitudinal motion of the armature and its shaft brings the spur wheel into mesh, and subsequently disengages it. The series-wound starting motor has four poles. One pair of these is wound with comparatively fine gauge wire, and the other with comparatively large gauge wire. Of the three brushes on the commutator, two are main ones. The other is a subsidiary brush, capable of short-circuiting a section of the armature winding. When the foot switch is pressed down, the first result is to bring all these three brushes into action, using only the poles wound with fine wire. The current converts the armature into a magnet, which, in turn, draws the armature shaft endways until the pinion comes just into mesh with the spur wheel. A quick thread on the armature shaft brings the two into mesh as promptly as possible, running the pinion rapidly along into line with the spur wheel on the engine fly-wheel. In synchronism, a further pressure of the foot switch throws the subsidiary short-circuit brush out of action, and brings into circuit the pair of poles wound with heavy gauge wire. They come into circuit in parallel with the other field windings, whereupon the motor develops full power for the purpose of rotating and starting the engine of the car. The driver has merely to remember that he should depress the starter switch slowly but firmly. A momentary pause is observable at about half its traverse. A little grease should be applied occasionally to the pinion, fly-wheel gear, and the screw of the shaft extension and springs. The grease cups of the motor should be refilled periodically, at which intervals a few drops of oil should be supplied to the dynamo bearings. Flanges are furnished to the plunger type switch designed to be used with this starter. By this means the switch can be fitted under the floor boards of the car or in other convenient places determined on for foot operation. The apparatus is made in three sizes. The first is for engines up to 16 horse power, the middle range for those up to 40 horse power, and the largest of all for car engines or marine motors not exceeding 150 horse power each.

WAR AND ALCOHOL.

THE seventh Norman Kerr Memorial Lecture of the Society for the Study of Inebriety was delivered by Major W. McAdam Eccles, surgeon to St. Bartholomew's Hospital, last week. He said that nearly half of the population of the British Isles were total abstainers, but that

the sum of £200,000,000 sterling was spent on excisable alcoholic beverages. They were drunk for the alcohol they contained far more than for the small amount of food present, and the question was whether the alcohol was beneficial or harmful to health and efficiency. Ethyl alcohol as a food was not essential and most expensive, so that it was a "luxury" food. Any part of the supply used for human consumption was wasted, but alcohol was essential for manufactures connected with the war; if there were not enough alcohol for the industrial, chemical, and scientific purposes for which it was essential, its human consumption was direct waste. Although the present industrial unrest had resulted from the scarcity and high price of beer, the majority of the female munition workers were able to perform their duties and keep in good health without alcoholic beverages. Proper industrial use had not been made of alcohol in this country. The German empire was shorter of petrol than the British, but the German chemist had manufactured cheap alcohol, and the German engineer had made engines to be driven by its combustion. Even if there were no war, it would be a sound policy to manufacture methyl alcohol for motor purposes. As it was, all the alcohol now in bond in this country and all the alcohol made by distillers and brewers should be used for munitions, motive power, and industrial and scientific purposes. His general conclusion was that alcohol before the war was greatly to blame for poverty and inefficiency. During the war it had tended to prolong hostilities and to render hardships more numerous and more difficult to bear; during demobilization it might lead to very serious consequences.

MEMORIAL SCHOLARSHIPS.

THE Royal Medical Benevolent Fund Guild has undertaken the administration of an educational fund which has been raised by the friends of the late Mrs. John Phillips to perpetuate her memory. Mrs. Phillips, at the time of her death, was one of the members especially engaged upon making more widely known the work of the Guild in aiding necessitous families of the medical profession. A sum exceeding £500 has already been raised to found a scholarship or exhibition, and as the fund is still open, it is hoped that the amount will be materially increased. Mrs. Muir (Honorary Treasurer), "Vellow Wood," Weybridge, will be glad to receive subscriptions. A sum of £368 has also been allocated to the Royal Medical Benevolent Fund Guild by the friends and patients of Dr. L. Vernon Jones who died a year ago. The annual income of both these memorial funds will be administered by the Guild for the educational benefit of the children of those who are beneficiaries of the Royal Medical Benevolent Fund.

Medical Notes in Parliament.

Parliament at Work Again.

PARLIAMENT has resumed its sittings after a recess of a little more than seven weeks, and the probability is that the session will not be concluded much before Christmas. The redistribution clauses of the Reform Bill came up for consideration this week, and it was natural, both for local reasons and as they involved an enlargement of the membership of the House of Commons by thirty-one members, that they should require careful attention. It has long been held that the membership of the House of Commons should not be increased, and the Speaker's Committee did not favour an increase. On the other hand, it is pointed out that "if and when" Home Rule for Ireland operates, the membership at Westminster will be reduced by more than thirty-one, and it is urged that the Boundary Commissioners found the task of preserving natural boundaries for constituencies within the old total to be impossible, and that they were bound, therefore, to exercise discretion. The scheme disclosed in the schedules

provides an increase of university representatives in Great Britain from seven to ten. The Universities of Oxford and Cambridge would retain two members each, but the University of London would be linked with the Universities of Durham, Manchester, Liverpool, Leeds, Sheffield, Birmingham, Bristol, and Wales, in a joint constituency returning three members. It is proposed also to link the Scottish Universities into a single constituency represented by three members. The hope is that the bill will be passed through the Lords by the end of the year. Unless there is to be a general election on the old register and before Christmas, a bill to extend further the life of the present Parliament will be required this autumn. The existing extension carries only to November 30th.

Discussions on the conduct of the war will occur on the next vote of credit, which will be needed within a few weeks. Since the opening of the financial year the sum of £1,500,000,000 has been voted, as against £2,010,000,000 for the whole of the financial year 1916-17, and the rate of expenditure continues to rise. The expectation is, however, that as America is now participating so thoroughly in the war, our loans to allies will be lower than in recent votes.

Mr. Lloyd George's reply to a deputation dismissed any lingering hope of action being taken in the near future to set up a Ministry of Health. The Prime Minister, while expressing sympathy with the project put forward by Lord Rhondda when at the Local Government Board, intimated that in the present stage of the war it could not be done.

It is stated that Sir Edwin Cornwall, Chairman of the Joint Committee of Insurance Commissioners, intends to introduce a bill to remedy defects in the machinery of the Insurance Acts. The finances of the Acts will also require attention. To meet the deficiency a grant of £500,000 has already been made, but the Prime Minister has announced that the Government proposes to grant £250,000 a year in addition to the £150,000 promised by the Ryan Committee.

There appears reason to hope that the Education Bill, introduced by Mr. Fisher just before the House adjourned, may be passed this session. It is based on the lines of his Education Budget speech. Its provisions have been generally approved, but it is a bill which will require a good deal of time for consideration on account of its scope.

Mr. Bonar Law stated on Tuesday that a bill to constitute an Air Ministry would shortly be introduced. Meanwhile General Smuts would continue to supervise the Air Service. In cross-examination by Mr. Kennedy Jones and Mr. Pemberton Billing, Mr. Law said there had been no change of policy on the part of the Government as to air raid policy. It was intended to employ our machines over German towns so far as military needs rendered us free to do so. Our course of action depended, he said, "on the best way of damaging the enemy."

There will be a medical interest--as regards the treatment of hunger strikers in prison--in the Irish debate to take place in the Commons on Tuesday. Mr. Redmond's motion, which asks the House "to deplore the action of the Irish Executive and Irish military authorities," arises out of the death of Thomas Ashe, which occurred after hunger striking, some short time after his release from a Dublin prison. Mr. Duke said on Tuesday that he believed that no Irish prisoners are now being forcibly fed. It is reported that four who had been on hunger strike in Cork prison have been released.

It is understood that a motion in gratitude to our fighting forces is to be moved in both Houses of Parliament. Usually such a tribute is deferred until the end of a war, but it is felt that the prolonged and tremendous character of the present conflict makes the exceptional tribute appropriate and desirable.

A seat is to be found for the Minister of National Service (Sir Auckland Geddes) in the Basingstoke Division of Hampshire, where a vacancy has been produced by the appointment of Mr. Clavell Salter, K.C., to be a judge.

THE Calendar of the Royal Society of Medicine for 1917-18 contains a diary of the meetings of its twenty sections, with particulars of their officers, a short history of the foundation of the society, an enumeration of the privileges of Fellows, and of the subscriptions paid by them and by members of sections who are not Fellows.

THE WAR.

THE ARMY MEDICAL COLLECTION OF WAR SPECIMENS AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ADMISSION OF SIR ALFRED KEOGH TO THE HONORARY FELLOWSHIP.

THE collection of war specimens formed under the aegis of the Royal Army Medical Corps, with the main object of serving the needs of the members of that body, was opened on October 11th. The collection has been rearranged and much extended since last we referred to it; it now occupies three rooms, two of them among the largest in the college buildings. The ceremony was attended by a large and distinguished audience, who doubtless desired to take the opportunity of testifying by their presence the admiration inspired by the eminent services rendered by Sir Alfred Keogh to the country and to surgery.

PRESIDENT'S ADDRESS.

The President, Surgeon-General Sir GEORGE MAKINS, said:—Gentlemen: It is with a feeling of the warmest satisfaction that we meet you here to-day, not only because the Council welcomes any occasion of receiving the profession within these walls, but also because we can congratulate this College on adding to the important personal services which have been rendered to the empire by its Fellows and Members one other item, scarcely less important for the future—the provision of a permanent record of the injuries and diseases from which our fellow countrymen have suffered during the great war. As to the details of the measures which have been taken to allow of the assemblage of specimens and drawings which you will shortly visit, Sir Alfred Keogh will address you, but I cannot omit on the part of the Council to mention the debt of gratitude which we and the country owe to our own officers. Sir John Bland-Sutton, Chairman of the Museum Committee, has spent time and labour on the scheme. Our Conservator, Professor Keith, has worked with untiring enthusiasm at every detail. Professor Shattock and Mr. Beadles have produced dissections of which their scientific ancestor, Mr. Hunter, would have been proud, and they have been seconded by the sadly depleted museum staff in the most loyal manner. The aid rendered by these gentlemen is an earnest of the close co-operation of the civil and military branches of the profession, and will remain a permanent record of its intimate character for all time.

Gentlemen, I have one further duty to perform, that of introducing to you the Director-General of the Medical Service of the Army, and welcoming him as an addition to the roll of Honorary Fellows of this College. You are already acquainted with his public career. I have had the privilege of working with him and under his direction and control through not a small part of its most active and fruitful stage. My first introduction to his name was when the P.M.O. of the South African Field Force said to me with satisfaction in the midst of difficulties that Major Keogh was arriving in the country. Later, I witnessed his success as an administrator in that country and the valuable services he rendered on Mr. Brodrick's Committee, to the work of which much of the success attained in the present war must be attributed. Still later, Sir Alfred Keogh himself was chosen to develop the lines laid down by that Committee, with a degree of success that is known to us all. The Royal Army Medical College remains as a monument of his effort to improve both the scientific and social status of his colleagues. Lastly, his judgement and far-seeing policy led him to apply all his energy to the development of the Territorial Medical Service, at a time when too little was thought of the all-important duties which it might be called upon to perform at a not very distant date. The lapse of time and office caused his transference to a new sphere, where his energy, capacity, and enthusiasm was opening up a future for technical science, which may have a greater opportunity to fructify when war is over than might have been the case had the country continued to enjoy an undisturbed peace. Recalled from the realms of technical science he has been faced with the most stupendous task which ever

tried the resources of a Director-General—the administration of the medical service of four armies any one of which is greater than had ever left our shores, and right loyally has he faced the difficulties with untiring devotion, foresight, and success. Great as all these services had been, it is perhaps in one other respect that Sir Alfred has shone pre-eminently in office. I refer to the strenuous and successful efforts which he has made to unite the civil and military elements of the profession in one united body. The improvement and approximation of the relations existing between us has not been a mere matter of pursuing a general policy, but one of personal solicitude, and to-day he has gained the respect and the affection of us all. Ever ready to listen to suggestions, to act promptly upon them if feasible, his whole aim has been to further the success of medicine, and thereby to raise the position and importance of the profession. Gentlemen, he has our thanks.

Then, addressing Sir Alfred Keogh, the President said: "In electing you an Honorary Fellow of this College, its Fellows and Members are conferring upon you the highest honour it is in their power to bestow. You may look with satisfaction—and, I think, a justifiable pride—at the list of distinguished men to which your name has now been added, and may you remain strong and active to complete your present labours, and carry out the great work which has been interrupted by the all-absorbing duties of the moment."

SIR ALFRED KEOGH, in expressing his thanks for a dignity which he recognized was not often conferred, said that he knew that in honouring him the College was honouring also the service to which he belonged, and expressed his consciousness of the help and kindly advice and counsel received from the profession in the organization of the medical arrangements of the five campaigns in which the country was involved. Turning then to the exhibition, which he formally declared open, he said that it would have rejoiced the heart of John Hunter, who did in his time so much to promote knowledge of the injuries of war. Hunter's views in certain branches had been fully vindicated by recent experience. The exhibition was intended to be educationally useful at once and also to serve as a record for the instruction of the future. He paid a tribute to the work of Dr. W. M. Fletcher, F.R.S., and Sir John Bland-Sutton, in England, of Lieut.-Colonel T. R. Elliott, F.R.S., in France, of Captain Bartlett in Egypt, Colonel Lister, C.M.G., Mr. Izzard of Cambridge, and to the staff of the Museum of the Royal College of Surgeons, especially to Professor Keith, who had made the collection a real living thing. All the Dominions were represented in the collection, but the specimens remained theirs, and would, he hoped, form the nucleus of others in their own countries. He hoped the military hospitals would each form collections out of the abundant material available, and that from these contributions might be made to complete that at the Royal College of Surgeons.

THE PURPOSE AND NATURE OF THE COLLECTION.

The collection, as has been said, has been greatly enlarged, and as opportunity and time permit will be steadily increased. Meanwhile the following account, slightly shortened from a guide written by Professor Arthur Keith, will be read with interest, and may serve to stimulate further contributions, especially in those directions in which the collection is at present deficient.

PART I.—HISTORICAL.

In November, 1914, a Committee was constituted under the presidency of the Director-General of Army Medical Services—Sir Alfred Keogh—to compile a medical history of the war. One of the aims of this Committee was to collect from casualty clearing stations and military hospitals examples of the wounds and diseases suffered by soldiers in the present war; to dissect and examine such specimens in order to fully understand their extent and nature so that the best means might be adopted for their treatment; and to preserve instructive examples so that they might be examined and studied not only by army surgeons of to-day, but also by medical men for many generations to come. Such examples or specimens are original documents; they constitute an original and reliable source of knowledge for all time.

It can be readily understood that in the earlier phases of the war, when every endeavour had to be concentrated on the immediate medical needs of the army, the depleted staff of the Army Medical College at Millbank was not in a position to undertake the formation of such a collection as the Medical History Committee had in view. Hence, in May, 1915, Dr. W. M. Fletcher, Secretary of the Medical History Committee, asked the assistance of the Council of the Royal College of Surgeons, which at once placed its museum staff and workrooms at the disposal of the Army Council. Memoranda were issued detailing the aims of the Committee and the methods to be observed in selecting, preserving, and dispatching of specimens, and in January, 1916, Lieut.-Colonel T. R. Elliott, F.R.S., was placed in charge of this particular service in France. Specimens then arrived in numbers; they were selected examples preserved by the latest and best methods. Lieut.-Colonel Elliott was successful in enlisting the willing co-operation of younger pathologists attached to the clearing stations and hospitals in France—Captain Herbert Henry, Captain H. W. Kaye, Lieutenant T. G. Shore, Captain G. Richardson, Captain Adrian Stokes, Captain Lazarus-Barlow, Captain E. M. Cowell, Major J. W. McNee, Captain A. Petrie. Specimens from Egypt represented the diseases and wounds of the campaign in Gallipoli, those sent by Captain G. B. Bartlett, R.A.M.C., being of particular value. In the spring of 1917 Lieut.-Colonel Sir John Bland-Sutton was appointed by the Director-General to organize the collection of specimens from hospitals at home, particularly hospitals at which particular kinds of wounds are being treated, and in that direction, too, the objects of the Medical History Committee are now being fulfilled.

Owing to the depletion of the museum staff of the Royal College of Surgeons by the war the original intention on the part of those responsible for the collection was to postpone the examination, study, and exhibition of specimens until the end of the war, when a body of experts could be appointed for this purpose. But it was urged by Sir Arthur Sloggett, the Director-General of Medical Services in France, that the collection possessed an immediate educative value for the medical officers now serving with His Majesty's forces. Arrangements were accordingly made to proceed with the preparation of specimens for exhibition, materials for their preservation and exhibition being supplied by the War Office, and the Medical Research Committee giving financial assistance. Mr. S. G. Shattock, F.R.S., pathological curator to the college, and Mr. Cecil Beadles, assistant curator, undertook the dissection, examination, and exhibition of wounds as they affect the various systems of the body—bones, muscle, joints, blood vessels, deeply seated organs, etc. Captain Raymond Johnson, R.A.M.C., gave assistance in selecting specimens of surgical interest. The conservator of the museum, Professor A. Keith, assumed responsibility for the description and arrangement of macerated specimens illustrating the lesions inflicted by modern missiles so far as bones and joints are concerned. These preparations were obtained partly from No. 1 Eastern General Hospital, Cambridge, and partly from hospitals in France. The greater number of these excellent and instructive war records are the work of Sergeant F. A. Izzard, of the Pathological Museum, University of Cambridge. Many, too, are owing to Captain G. Richardson, who applied new methods for the preparation of such specimens. The responsibility for arranging and cataloguing the collection of skiagrams, many of them of great merit, the workmanship of Captain H. E. Gamlen and of Dr. Florence Stoney of Fulham Military Hospital, was undertaken by Mr. R. H. Burne. Dr. W. Colin Mackenzie rendered a constant and valuable service by indexing all specimens as they arrived.

From the commencement of the enterprise an imperial view of its possibilities has been taken. The aim has been not only to build up a "central" or "national" collection, but also to encourage the Canadian, Australian, and New Zealand Army Medical Services to share in a common endeavour. Such specimens as are sent by these services are ear-marked for special collections to be set up in Canada, Australia, and New Zealand. In every case where the Medical History Committee does not desire to retain a specimen for the "national" collection the sender has the right to have such specimens forwarded to the medical museum of his university or hospital.

Besides specimens derived from this war there have also been placed on exhibition for the purposes of com-

parison the sparse records that have come down to us from former wars. Such specimens and also drawings have been obtained from the Museum of the Royal College of Surgeons, St. Thomas's Hospital, University College Hospital, and the Royal Army Medical College at Millbank.

These collections will arouse a feeling of regret that military surgeons of former campaigns had not taken pains to preserve the medical and surgical conditions they were called on to face. It is so hard for a surgeon to realize that the conditions he is only too familiar with in the heat of a campaign are unknown to those who do not share with him the labours of the field and will also remain unknown to those who have to undertake the care of soldiers in future unless a record is made. It was to secure the fruits of our experience—for our present as well as for our future needs—that the Medical History Committee was constituted; the collection, examination, and preservation of examples of wounds and diseases is only one of the many methods it has adopted to secure its chief object—the recording of experiment and experience. Many of the most valuable records appear weekly, monthly, and quarterly, in medical and surgical journals.

There are certain conditions which must appear but rarely in the experience of the individual surgeon and are yet not uncommon when experiences are pooled. Almost at the commencement of the war a heart was received from which a surgeon had successfully removed a bullet when the soldier was alive, and no wound of entrance to the heart was perceived at the time of operation or afterwards. Soon two similar examples of fragments of metal in the heart were received, and are now exhibited. It was then inferred that such foreign bodies must first enter a large vein and be subsequently swept on to the heart in the circulation. Further experience has shown that such is their origin; cases in which foreign bodies such as bullets and fragments of shell have been swept into the heart are by no means rare. Another set of cases may be cited. Quite early in the war three examples of fracture of the neck were received—one from England, one from Egypt, and one from France. All three were caused in the same way: in each case the soldier had dived into shallow water and his head had struck the bottom. An examination of such specimens showed that in most cases the lives of such soldiers could be saved by the prompt adoption of certain means, and that death will certainly be produced by improper handling. Many more could be cited in support of the immediate utility of a central army collection of pathological specimens.

In peace medical men in search of the newest knowledge and latest means of treatment go from hospital to hospital and watch the practice of physicians and surgeons. In war those who have such objects in view must visit the various military hospitals in which special work is being done. The best knowledge can be obtained only at original sources. Much, however, can be done for the dissemination of knowledge—as well as making known deficiencies in our knowledge—by means of such a central exhibition as that now opened at the Royal College of Surgeons. It could be arranged for special and general hospitals to make such an exhibition a centre for the exchange and spread of knowledge. To take an instance: the exigencies of the present war have led us to revise completely the means by which we obtained full immobilization of joints and limbs. It would be possible to give a concrete representation of the various splints and their proper application—according to the teaching of the school represented by Colonel Sir Robert Jones. It is hoped that additions of this and of many other kinds will be made to the present exhibition.

The real nucleus, the essential part of the present exhibition, is the dissections made by Mr. S. G. Shattock and Mr. Cecil Beadles, which now occupy Room II of the museum. Each specimen represents an exact investigation of a wound or injury, made in such a way as to permit the visitor to gain at a glance results which have taken the investigators laborious pains to elucidate. The dissections actually displayed are little more than a tithe of material which awaits a fuller investigation.

It is only right that acknowledgement should be made here of the great services rendered by Lieut.-Colonel T. R. Elliott. Without his foresight, energy, judgement, and enthusiasm, the collection, planned by the Medical History Committee, could never have been realized. To Captain

E. M. Cowell must also be given the special thanks of the Medical History Committee; at personal risk he has secured records of great value.

PART II.—DESCRIPTION.

The collection is displayed in three rooms of the museum, in peace devoted to the exhibition of anatomical and pathological preparations, many of them the work of John Hunter, and most of them mounted in glass jars filled with inflammable spirit. At the outbreak of war they had to be placed in cellars for safety, for those in authority well knew that the people who trained their guns on the invaluable collections of the Natural History Museum of Paris in the spring of 1871 would not respect any British collection, no matter what its scientific value or humanitarian worth might be.

Means of Protection.

In Room I a section thus labelled includes metal helmets, breast-plates, masks, respirators; and other inventions employed for the protection of soldiers. Several helmets are shown bearing evidence that the head of the wearer has been saved from a wound which otherwise would have proved mortal. With these helmets are shown a series of calvaria, perforated, with fatal results, by missiles which could have been turned aside by protective helmets. The gas masks for the protection of the lungs are of various patterns and dates.

Wounds of the Skull.

This series begins with examples of extensive destruction—injuries caused by large fragments of shell or by bullets of high velocity—giving rise to an "explosive" effect, a shattering of the whole skull. Then follow examples of minor wounds of the forehead and frontal bone, showing many forms and many stages of healing, and of wounds caused by missiles which have passed through the skull from side to side. These may be named "bifrontal," "biparietal," or "bioccipital," according to the site of injury. Others illustrate the results of missiles perforating the head in an antero-posterior or oblique direction; such wounds we may name "fronto-parietal," "fronto-occipital," or "parieto-frontal," the first named bone being the site of the entrance wound, the second one that of the wound of exit. Examples of all of these varieties are to be seen, but "gutter" wounds, caused by a bullet or missile merely plunging the surface of the skull, are scarcely represented. Numerous examples illustrate the well-recognized fact that the injury to the external plate of the skull is no index to the extent of injury to the internal plate. There are two specimens in which a blow has caused a fracture of the inner plate of bone, and yet the corresponding outer plate remains intact. Other specimens are examples of injuries of the basal part of the skull, and others illustrate wounds and injuries of the face and jaws. In some cases of fractured jaw the dental splints which have been used to keep fragments in position are still attached to the specimens. Attention is particularly directed to the injuries of the lower jaw.

Injuries to the Spinal Column, Thorax, and Pelvis.

There is one remarkable specimen in this series, where the bullet has entered and passed along the spinal canal in the dorsal region, shattering the laminae as it passed; the bodies of the vertebrae are fissured on the median plane—showing the rending or "explosive" effect of a bullet of high velocity. Several other specimens show fissures in bodies of the vertebrae. Gunshot injuries of the sacrum and pelvis of various kinds are illustrated, but injuries to the ribs and sternum are as yet meagrely represented.

Injuries of the Limbs.

In the series showing injuries to the bones of the shoulder, the shoulder-joint, the arm, elbow, wrist, and hand, all the bones of the upper extremity are represented, and there is a most instructive series illustrating injuries to the lower limb. The series begins with the manifold injuries of the hip-joint and the results which follow such injuries. There follow illustrations of fractured thigh-bones. A study of these specimens will show that there are several types of fracture produced by missiles, but the prevailing type is that described by the term

"butterfly" or X-shaped type. There is a tendency for a bullet to break the part of the bone into two main fragments resembling the two wings of a butterfly. In most cases the articulator has restored these fragments to their proper place in the whole bone, thus giving a somewhat misleading idea, except to the expert, of the disorder produced by a bullet wound of a bone. It will also be noted that most bones which have been struck by projectiles show fine fissures far beyond the point of impact. A gunshot injury of bone produces a much more extensive rupture and exposure of torn surface than a mere casual examination reveals.

The specimens of injuries of the lower limb form a continuous series—injuries of the knee, injuries of the leg, the condition of "stumps" removed by secondary amputation, injuries to the ankle and foot being represented in a consecutive manner. There is one remarkable instance amongst the injuries of the bones of the leg—one where the lower end of the broken tibia has become united to the upper end of the broken fibula.

Wounds of Soft Parts.

The specimens prepared by Mr. S. G. Shattock and Mr. Cecil Beadles are displayed in Room II. They form the essential part of the exhibition, for they give an opportunity of studying in their immediate and in their remote effects the peculiar characters of the wounds met with in modern warfare. Such examples as are available from former wars—chiefly dried or bone preparations, and also examples of gunshot wounds culled from civil practice—form a group by themselves. The Napoleonic wars are represented by specimens from soldiers who fought with Sir John Moore in his retreat to Corunna, and there are a very few examples from Waterloo. Examples of the wounds and injuries of the Crimean war are more plentiful; there is quite a good series from the Austro-Prussian and Franco-Prussian wars—those from the latter war having been collected by Sir William MacCormac. In those wars the same type of bone injury, the same septic inflammatory sequelae, are to be seen as have been noted in the present war, for the wounds produced by shrapnel and by shell fragments are of the same nature now as in former wars; the septic sequelae are also the same. It is not, however, until we come to the examples obtained from the Sudanese campaign of 1898 that we recognize the results produced by missiles of high velocity—the shattering, expansive, "explosive" effects of the more modern missiles. Examples of the more modern rifle ammunition are displayed as well as a number of models obtained by the late Sir Victor Horsley from his experiments to demonstrate the explosive effects of high velocity bullets, by firing into blocks of soft clay.

Opportunities for the study of modern military wounds are next afforded—wounds of entrance, wounds of exit, wounds at various stages after the date of infliction, in various stages of healing, and in various stages of sepsis, and there are specimens also of "excised wounds." The next series illustrates injuries to the chest, pleura, and lungs, with the various sequelae which may follow such lesions, and hard by are examples of wounds of the structures in the posterior mediastinum—of the oesophagus and aorta; then of the diaphragm, and finally of the heart. There is one very remarkable injury of the heart: the anterior wall of the right ventricle is extensively lacerated—yet the officer (a member of the Flying Corps) brought his machine safely to earth! A very complete representation has been obtained of the forms of vascular injury so common in this war. The majority of these have been selected and recorded by Surgeon-General Sir George Makins, President of the College. One preparation on this stand particularly worthy of study is a dissection of the popliteal space which has been pierced by a bullet of high velocity. The damage is seen to extend far beyond the immediate track of the missile. Other series represent gunshot injuries of the liver, the bowel, the stomach, the kidney, and bladder; of the spleen, larynx, and spine, and lesions of the spinal cord.

On a screen are displayed most accurate delineations of war wounds by Sgt. A. K. Maxwell, who has succeeded in rendering a permanent and faithful record of conditions which could not be recorded except by pen and brush. His rendering of the appearance of muscles at various stages of invasion by the bacillus which produces gas

gangrene are particularly worthy of attention. Some of them were reproduced in colours in the issue of the *BRITISH MEDICAL JOURNAL* for June 2nd, 1917.

Another series of specimens represent the lungs of men who suffered in the first cloud of poisonous gas sent over our lines by the enemy early in 1915—at Ypres. The effects of that poison may be studied at all stages, early and late, the effect on the whole respiratory system. There is also a series of kidneys from cases of trench nephritis, and another of the conditions, organic disturbances, and disorganization produced by the gas-producing organism, *Bacillus aerogenes*.

Illustrations of Successful Treatment.

Many of the specimens represent surgical measures which saved the lives of soldiers—such as excised wounds, excision of parts of lacerated bowel, removal of dead and infected tissues. The successful aspect of surgery is more fully brought out in the collections of drawings, models, casts, and apparatus for treatment to be seen in Room III. Apart from the operations on fractured limbs which have furnished many specimens, there is, it is to be remembered, the vast number of cases where damaged limbs, even after compound and infected fracture, are saved by the various methods of combating infection. Such successes cannot be represented in such a collection as is shown in Room II. One can see, however, that no organ lies outside the range of modern surgery; cases where the heart has been successfully operated on—death resulting from some lesion elsewhere in the body—are represented. Missiles lying in the ventricles have been removed and life saved.

In one group of specimens are shown successful operations of a general kind, as distinguished from those upon special parts like the face and mouth. This group comprises successful removal of injured kidney or spleen, of pieces of wounded blood vessels, cases where vessels have been successfully sutured, the successful removal of wounded loops of intestine, artificial union of the fractured ends of bones, removal of large fragments of bone or even entire bones, such as the astragalus and scapula, resulting in the saving of limbs.

Some Groups and Blanks.

The specimens in Room III are set in groups, each group or section being the work of a single hospital or of a single individual, an arrangement which gives visitors an opportunity of learning at a glance the methods practised at particular hospitals, and the results which attend the application of such methods.

Not any part of this exhibition is really complete; every section is capable of extension and improvement, and there can be no doubt that as time goes on and visitors become aware of the utility and needs of the collection that additions will be made. That statement is likely to prove especially true of the sections now shown in Room III.

Reference may first be made to a series of drawings by Sir Charles Bell, borrowed from the Museum of the Royal Army Medical College. They were done in Belgium when he was studying and treating the wounded from Waterloo. Some of the wounds represented are rarely seen in the present war—the dragoon with sword wounds of the head and neck, the French soldier with the sloughing colon protruding from a sabre wound of the abdomen, the Hanoverian soldier whose right arm has been removed by cannon shot (“left to Nature and returned to Hanover in December, quite well”)—are all uncommon nowadays. On the other hand, another (a lower limb with gunshot fracture of the tibia) represents a condition as common to-day as in 1815. The same may be said of the pictures which represent gunshot wounds of the shoulder and head. On the wall, beyond Sir Charles Bell’s drawings, is a series of sketches by Colonel F. M. Caird representing certain conditions studied by him in France. The various stages in the development of “trench foot” are portrayed; there are rapid drawings of the conditions resulting from guillotine amputations, and pictorial notes of the effects of “Yperite”—one of the poisonous offensive German gases. Then follow a collection of Sergeant A. K. Maxwell’s drawings, and also excellent drawings by Mr. S. A. Sewell. In this room are a series of specimens, for which Major Valadier, R.A.M.C. (No. 13 Stationary Hospital, B.E.F.), and H. L. Whale, R.A.M.C., are responsible, illustrating the

nature of the jaw wounds and facial injuries, and an exhibit from Queen’s Hospital, Sidcup (formerly Cambridge Hospital, Aldershot) of wax models, plaster casts, and a series of strong and vivid drawings by Professor Henry Tonks, F.R.C.S., of the Slade School of Art, depict for the visitor the facial deformities which Major H. D. Gillies and Captain J. L. Aymard are called on to treat, the methods which they invent and adopt, and the degree of success which attends their efforts.

On a stand in the centre of the room, immediately in front of the Hunter statue by Weekes, is placed Colonel W. T. Lister’s collection of injuries and wounds of the eye, and a series of drawings elucidates the functional and clinical disturbances which were observed in each case. There is also a large collection of casts, models, and splints from Queen Alexandra Military Hospital, Millbank, for which Captain F. A. Hort, R.A.M.C., is entirely responsible. We see here the art of the cast-maker put to a double purpose: (1) To record clinical conditions, such as flat-foot and paralytic deformities—the same parts under various degrees of action and at various stages of development; (2) to supply those who have to fit splints or artificial limbs with an accurate basis on which to mould their appliances.

Those who are responsible for the exhibition have the hope that the exhibits in Room III will be extended in scope and character. They want to see models demonstrating the most recent and effective methods of applying splints so as to secure perfect immobilization of fractured parts. It is possible, too, that such collections as are now shown in Room III might become the centres round which surgeons from special military hospitals could meet for informal conferences concerning the best methods of treating particularly difficult cases of military injury.

THE WOUNDED FROM THE PASSCHENDAELE ACTIONS.

THE weather we have recently been experiencing in this country makes it easy to understand the accounts given by correspondents of the condition of the ground in Flanders and of the extreme difficulty not only of the advance of the troops but of the carrying back of the wounded.

In August, by means of trench tramways, corduroy roads, and so on, it was comparatively easy to get up to the advanced dressing stations and from the advanced dressing stations to the regimental aid posts. As soon as the ground in front of a jumping off point is assuredly taken, the trench tramways and corduroy roads are pushed up with extraordinary rapidity, and though intended primarily to facilitate the bringing up of ammunition and other supplies they can also be used for bringing wounded down. Corduroy roads, however, are usually few and far between, and carrying stretchers to them over heavy ground is very laborious; it is not easy to walk on a corduroy road, for, unless the rain has been recent and heavy, it is covered with slippery mud. Further, it is to be remembered that there must be a greater or less extent of ground in front of the point to which any corduroy road or trench tramway can be taken, and that a considerable number of hours must elapse before either one aid or the other can be extended beyond the point to which it had been brought before the offensive started. Consequently there is always a time during which casualties have to be collected over a scattered area and carried over rough ground. The distance in the present war over which a casualty has to be carried may be anything from two or three yards to two or three miles—that is to say, the distance between the place at which the man falls and the place at which his bearers reach anything like a real path. The difficulty of carrying depends partly on the patient’s weight and partly on the character of the ground surface over which he is carried. The weight of a man ordinarily weighing 11 or 12 stone may easily be brought up to 13 or 14 if his clothes are soaked with rain or mud; and if the ground is soft or the rain has been heavy, the bearers may sink at every step over the ankles.

These are the conditions on high-lying ground at the best of times, except in very dry weather. They have often been very much worse, so that it has been difficult to walk without falling or dragging a leg every now and then out of a knee-deep or thigh-deep mudpit. The present

conditions are apparently as bad as, if not worse than, at any previous period. The going over the country where the actual fighting is taking place, or, rather, where the front-line casualties are occurring—that is to say, alongside the corduroy roads and beyond the points to which they reach—may not be more difficult than it was on some portions of the Vimy front during the spring offensive, or during the later stages of the Somme and especially the Ancre offensives. Be this as it may, the difficulties must now be very great owing to the contour and character of the soil; eye-witnesses find it impossible to describe a strip of Flanders after it has been ploughed up for days by shell fire. There are many places—almost, in fact, the whole ground east and north-east of Ypres—which closely resemble the ground where the fighting in front of Passchendaele is now taking place. Even the rising ground is little above sea level, and the shallow valleys are commonly below it. The soil is of such a character that, after heavy or continuous rain, water lies on the surface even of slopes, and anyone walking across these slopes sinks to the ankles. Lower down the water is not merely visible here and there, but forms marshes, interspersed at places by regular lakes. It is easy to understand that when such country is exposed to heavy shell fire it is a matter of considerable difficulty to traverse it even unladen. The difficulty of collecting the wounded is increased by the fact that they may have fallen into shell holes anything from a foot to many feet deep. It often takes hours to carry a single case a couple of miles, even if ample relays of bearers are available, and meantime the bearers are exposed to shell fire and sniping. The account given in the *Times* and other newspapers last Monday is, we believe, in no wise exaggerated.

Once the patients have been got back as far as an advanced dressing station progress is rapid, but it is impossible not to believe that the difficulty of getting patients to the advanced dressing stations, and their exposure meanwhile to rain and mud, must increase the aggregate number of cases in which profound shock occurs. Nevertheless the cases seem to be arriving at the bases in very good condition. The case mortality probably will prove to be low, and the number of amputations not high; the cases in which gas gangrene occurs would appear to be almost rare. There can be no doubt that the progress in this respect, even in comparison with recent offensives, has been considerable and that it is still more marked when compared with the position, say, as recently as eighteen months or two years ago. The explanation is probably to be found in the fact that the medical authorities have continued their policy of developing the work of the casualty clearing stations. They are placed not only in the rear of any part of the line where heavy fighting is expected, and are now so numerous that they can deal with an enormous number of casualties if required, but they are also so staffed that they can perform a very large number of operations. They are not so staffed permanently, but they are so staffed by the addition of surgical teams whenever an offensive is in view. It may be recalled that a surgical team consists of an operating surgeon accustomed to front line work and three assistants all of whom know his methods, one being an anaesthetist, another a nurse, and the third a theatre orderly. The net result is that though, in the first hours of an offensive, a certain number of patients may be passed through to a general hospital without operation at the front (when it is known that such hospital will be reached within six hours or so), the greater proportion of all cases are kept at the casualty clearing stations until they have been satisfactorily treated, and no seriously wounded men are allowed to pass through without having their wounds radically treated if necessary. This is of much moment, because there is no doubt that the final result in any case depends very much less upon any drug employed in its treatment than on its early and thorough surgical cleansing—by which is meant the excision of all damaged tissue before bacteria have had time to propagate themselves. There is equally little doubt that during recent operations hundreds if not thousands of limbs and lives have been saved which would have been lost at an earlier period of the war, and that very large numbers of men have been restored to the ranks within a few weeks who earlier in the war would necessarily have been lost. Both as an instrument for the reduction of suffering and for

keeping the British forces up to fighting strength, the medical machine is paying for itself over and over again. What is more, it is still being improved week by week.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Wounded.

Staff Surgeon E. L. Atkinson.

ARMY.

Killed in Action.

CAPTAIN D. AUCUTT.

Captain Donald Aucutt, Royal Warwickshire Regiment, was killed in action on October 9th, aged 24. He was educated at Alleyn's School, Dulwich, and King's College, London, and took the diploma of L.M.S.S.A. in 1914. He joined the Special Reserve of the R.A.M.C. in September, 1914, but resigned after a year's service and enlisted in the Royal Sussex Regiment, subsequently gaining a commission in the Warwicks, and was promoted to captain in July, 1917. He was the son of Mr. Aucutt of Denmark Hill, S.E.

CAPTAIN W. T. CHANING-PEARCE, M.C., R.A.M.C.

Captain Wilfrid Thomas Channing-Pearce, M.C., R.A.M.C., was killed in action on October 1st. He was the third son of Dr. J. Channing-Pearce of Ramsgate, and was educated at Guy's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1911, and at Cambridge, where he graduated B.A., and in 1913 M.B. and B.C. After filling the posts of obstetric resident and house anaesthetist at Guy's, and of house-surgeon to the West London Hospital and to the Croydon General Hospital, he took a temporary commission as lieutenant in the R.A.M.C. on October 5th, 1914, and was promoted to captain on completion of a year's service. He received the Military Cross so recently as September 26th last.

CAPTAIN J. DAVIE, A.A.M.C.

Captain James Davie, killed in action on October 6th, was the second son of the late John Davie and Mrs. Davie of Edinburgh. He received his medical education at the University of Edinburgh, where he graduated M.B., Ch.B. in 1909. He subsequently served the office of house-surgeon to the Peterborough Infirmary. Prior to joining the Australian Army Medical Corps he held the post of medical officer to the District Hospital, Jerilder.

CAPTAIN J. H. C. GATCHELL, R.A.M.C.

Captain James Harcourt Cecil Gatchell, R.A.M.C., was reported as killed in action, in the casualty list published on October 16th. He was a native of Dunamanagh, co. Tyrone, and was educated in Dublin, where he took the diploma of L.A.H. in 1912.

CAPTAIN T. J. GOLDING, R.A.M.C.

Captain Thomas James Golding, R.A.M.C., was reported as killed in action, in the casualty list published on October 10th. He took the diplomas of L.R.C.P.I. and L.R.C.S.I. in 1906, and went into practice at Cork. Joining the R.A.M.C. as a temporary lieutenant in 1916, he became captain after a year's service.

CAPTAIN K. T. LIMBERY, R.A.M.C.

Captain Kenneth Thomas Limbery, R.A.M.C., was reported as killed in action, in the casualty list published on October 11th. He was educated at St. Thomas's Hospital, took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1916, and immediately afterwards joined the R.A.M.C. as a temporary lieutenant, being promoted to captain after a year's service.

CAPTAIN L. OLDERSHAW, R.A.M.C.(T.F.).

Captain Leslie Oldershaw, R.A.M.C.(T.F.), was officially reported as having died of wounds, in the casualty list published on October 15th. He was the youngest son of Dr. G. Oldershaw of Walton, Liverpool. After studying medicine at Liverpool University, he graduated M.B. and Ch.B. in 1915, joining the R.A.M.C.(T.F.) immediately afterwards as lieutenant, and being promoted to captain after six months' service. He had served at Gallipoli and in Egypt, and was transferred to France last spring.

According to later information, Captain Oldershaw was killed instantaneously by shrapnel on October 2nd whilst returning from the firing line to the support trenches.

CAPTAIN W. D. REID, M.C., R.A.M.C.

Captain William Douglas Reid, M.C., R.A.M.C., was killed in action on October 5th, aged 30. He was born in 1887, the eldest son of the late Mr. John Reid of Blenheim, New Zealand, and was educated in New Zealand and at Edinburgh University, where he graduated M.B. and Ch.B. in 1910. He took a temporary commission as lieutenant in the R.A.M.C. on August 22nd, 1914, and was promoted to captain after a year's service. He was awarded the Military Cross on March 3rd, 1917, "for great courage and skill in tending the wounded under heavy fire, continuing to dress the wounded after being wounded himself."

CAPTAIN N. H. W. SAW, M.C., R.A.M.C.

Captain Noel Humphrey Wykeham Saw, M.C., R.A.M.C., was killed in action on October 9th, aged 25. He was the younger son of Mr. Samuel Saw of Blackbeath, and was educated at Guy's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1915. He at once joined the Special Reserve of the R.A.M.C. as lieutenant on February 10th, 1915, and was promoted to captain after a year's service. He gained the Military Cross on September 22nd, 1916.

Died of Wounds.

CAPTAIN J. J. P. CHARLES, R.A.M.C.

Captain John James Percival Charles, R.A.M.C., died on October 6th of wounds received on July 31st. He was the son of the late Professor Charles, M.D., of Queen's University, Cork, and was educated at Cork and at Edinburgh University, where he graduated M.B. and Ch.B. in 1909. After acting as house-surgeon of the London Lock Hospital and as house-physician of the Norfolk and Norwich Hospital at Norwich, he went into practice at Swanage. He took a temporary commission as lieutenant in the R.A.M.C. on September 1st, 1914, and was promoted to captain after a year's service.

Died on Service.

CAPTAIN J. W. PETTINGER, R.A.M.C.

Captain James Wilson Pettinger, R.A.M.C., died of pneumonia in the Military Hospital, Aldershot, on October 6th, aged 43. He was the son of the late Dr. George W. Pettinger of Manchester, and was educated at Cambridge, where he graduated B.A. in 1896, and M.B. and B.C. in 1902, and at St. George's Hospital, also taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1899. After acting as house-surgeon, house-physician, and assistant surgical registrar at St. George's he went into practice at Kingsbridge, South Devon, where he was honorary medical officer to the Kingsbridge and District Cottage Hospital. He took a temporary commission in the R.A.M.C. last year, and was promoted to captain after a year's service.

Wounded.

Major J. S. Y. Rogers, R.A.M.C. (T.F.).

Captain D. S. Cassidy, R.A.M.C. (temporary).

Captain W. McM. Chesney, R.A.M.C. (S.R.).

Captain A. R. Grant, R.A.M.C. (temporary).

Captain R. W. Hill, R.A.M.C. (temporary).

Captain W. McConnell, R.A.M.C. (temporary).

Captain A. E. Mackenzie, R.A.M.C. (T.F.).

Captain A. Morris, R.A.M.C. (T.F.).

Captain W. A. Rees, R.A.M.C. (temporary).

Captain S. J. Simpson, R.A.M.C. (temporary).

Captain H. F. Warwick, R.A.M.C. (temporary).

Captain W. F. Wilson, M.C., R.A.M.C. (T.F.).

Captain W. F. Young, R.A.M.C. (temporary).

Lieutenant G. S. Lawrence, R.A.M.C. (temporary).

Lieutenant R. C. Rogers, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Bartholomew, George Hugh Freeland, Captain Argyll and Sutherland Highlanders, second son of Dr. Bartholomew of Edinburgh, died of wounds October 2nd, aged 21. He was educated at Merchiston, and was entered for Corpus Christi College, Oxford, when the war began. He obtained a commission from the O.T.C. on January 4th, 1915, went to the front in June, 1916, and got his company in May, 1917.

Botting, William Ralph, Second Lieutenant Royal Sussex Regiment, elder son of the late Dr. Herbert Botting of Brighton, killed recently. Before the war he was assistant organist at St. Augustine's Church, Preston Park, Brighton.

Chalmers, H. Stewart, Captain Royal Field Artillery, second son of Dr. A. K. Chalmers, M.O.H. Glasgow, died of wounds September 29th, aged 22. He was educated at Glasgow Academy, and at Emmanuel College, Cambridge, where he was studying medicine when the war began. He took a commission in the 4th Lowland Howitzer Ammunition Column (T.F.) on December 8th, 1913, and went to the front early in 1917.

Chetham-Strode, Edward Randall, Captain Border Regiment, son of Dr. Chetham-Strode, of 60, Wimpole Street, London, killed October 1st. He was educated at St. Paul's, where he was in the eleven, and soon after leaving school went to Australia, but returned in April, 1914. He got a commission in the 3rd (Reserve) Battalion of the Border Regiment on October 14th, 1914, and went to the front in December, 1914, attached to the Duke of Cornwall's Light Infantry. He was invalided home in April, 1915, but returned to the front in July, rejoining his own, the Border, Regiment. He was wounded on June 28th, 1916, and again returned to the front in January, 1917.

Clarke, Arthur Aubrey, M.C., Captain Leicestershire Regiment, only son of Dr. Arthur Clarke, Breaun Down, Morley, Yorkshire, killed October 2nd. He got his commission in December, 1915.

Conway, Brian Wiseman, Captain Manchester Regiment, eldest son of Dr. Conway, of Overton House, Longsight, Manchester, killed October 4th. He was educated at Epsom College and at the Grammar School and University of Manchester, where he was a third year medical student when the war began. He enlisted in the R.A.M.C. in September, 1914, went abroad in that corps, and rose to be sergeant-major. He was given a commission in October, 1915, and was wounded in September, 1916.

De Denne, Thomas Geoffrey, Second Lieutenant 8th Devons, aged 27, youngest son of Dr. de Denne of Sidmouth, killed in action on October 4th. He was educated at Stoneygate School, Leicester, and Eastbourne College, and enlisted in Victoria, B.C., in September, 1914. He was wounded in May, 1915, at Festubert, got his commission in March of this year, and returned to the front in May.

Fink, Laurence Alexander Lewis, M.C., Captain Bedfordshire Regiment, son of Major G. H. Fink, I.M.S. (retired), killed October 4th, aged 26. He was educated at St. Paul's, and was employed upon a rubber plantation in Java when the war began. Returning home he got his first commission on April 27th, 1915. He got the Military Cross in October, 1916.

Fleming, H. W., Second Lieutenant Bedfordshire Regiment, second son of the late Dr. A. J. Fleming of Hampstead, killed October 5th.

Harington, William Guy, D.S.O., Major Indian Army, elder son of Lieut.-Colonel H. N. V. Harington, I.M.S. (retired), died of wounds September 28th, aged 32. He was born on May 5th, 1885, passed from Woolwich into the Royal Artillery on December 21st, 1904, and joined the Indian army, being posted to the 5th Gurkhas, on March 26th, 1908. He got his company on December 21st, 1913, and gained his majority and the D.S.O. in the present war.

Heald, Donald, Second Lieutenant Rifle Brigade, only surviving son of Dr. Hugh Heald of Abbotsford, Ormskirk, died October 6th of wounds received the previous day.

Joscelyne, Laurence Arthur, M.C., Second Lieutenant Somerset Light Infantry, only son of Dr. Arthur Joscelyne of Taunton, killed October 1st, aged 19. He was educated at Epsom College, where he passed the preliminary science examination of London University and gained a leaving scholarship at Trinity College, Oxford. He went to the front last January, and gained the Military Cross on August 16th.

Tobin-Willis, Jack, Lieutenant Royal Flying Corps, only son of Dr. Willis, and nephew of Dr. Tobin of Ilkeston, Derbyshire, killed in an air fight on August 17th, aged 21. He was educated at Douai Abbey and at London University, where he was studying law when the war began. He got a commission in the Army Service Corps on November 3rd, 1914, went to France in January, 1915, and served with the 1st Cavalry Division as supply officer, till he was transferred to the R.F.C. early in 1917.

Wayte, S. W., M.C., Second Lieutenant Royal Field Artillery, younger son of Dr. Waite of Croydon, died on October 7th of wounds received on October 4th, aged 22.

MEDICAL STUDENT.

Clark, Marcus Broadfoot, Lieutenant Argyll and Sutherland Highlanders, killed September 25th. He was the seventh son of Allan Clark of Cathcart, late of Severn Lodge, Inellan, and was educated at Glasgow High School and University, where he was a fourth year medical student before the war, and a member of the O.T.C. He got his commission on November 27th, 1914, and on January 11th, 1915, was posted to the Army Cyclist Corps, but subsequently rejoined his own regiment. He went to the front in 1915, was present in the battle of Loos, and was promoted to lieutenant in October, 1916.

The casualty list published on October 12th contained the names of four nurses, killed, presumably, by enemy aircraft dropping bombs on hospitals: Sister M. Milne and Staff Nurse A. Clime, both of the Territorial Force Nursing Service; and Nurses E. Thompson and D. Coles, V.A.D. nurses. A brief notice of Miss Coles was given in last week's number of the BRITISH MEDICAL JOURNAL.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

MILITARY ORTHOPAEDIC HOSPITALS IN THE UNITED STATES.
A DEPARTMENT of military orthopaedics of the United States Army has been established, with its head quarters at the Surgeon-General's office in Washington. Sites have been selected for orthopaedic war hospitals in nineteen cities of the United States, including New York, Philadelphia, Baltimore, Washington, Boston, and Chicago. Orthopaedic base hospitals are to be established near the front, where early treatment of injured and ankylosed joints will be given, and the new hospitals in the States will be used more especially for industrial training than for surgical treatment. There will at first be accommodation for 500 men in each hospital, but provision will be made for enlarging their capacity to 1,000.

England and Wales.

TAVERNS FOR MUNITION WORKERS.

THE Duke of Connaught, during a visit to the Enfield factories on October 12th, opened a reconstructed tavern in the neighbourhood, in furtherance of the experiment of the Central Control Board (Liquor Traffic), by which public-houses in certain areas are acquired and managed on behalf of the Board. The principle underlying this policy has been fully explained in the *BRITISH MEDICAL JOURNAL* in connexion with the experiments at Carlisle and the tavern opened last November at Enfield Lock. The Royal Small Arms Tavern at the gates of the factory has now been transformed. A dining hall has been built to accommodate 600 men at a time to a substantial dinner served from up-to-date kitchens, and the place is not only spacious but artistically pleasing. Nothing remains, either within or without, of the customary "decorations" of the public-house, nor of its close, unhealthy atmosphere; the new tavern, in spite of lattice windows and low rafters, has abundance of light and air. A salaried manager works under the Board, and has no inducement to press the sale of liquor; he is assisted by a committee of the factory workers themselves. The Duke said that he hoped the Enfield experiment marked the beginning of a better system for the supply of food to industrial workers in the intervals between their hours of labour, and he remarked upon the importance, not only of securing a sufficient and wholesome meal, but of obtaining it under comfortable and refined conditions.

MEMORIAL TO THE LATE MR. PUZEY OF LIVERPOOL.

On October 10th a memorial service was held in the chapel of the David Lewis Northern Hospital, Liverpool, when a tablet was unveiled and a chancel rail dedicated to the memory of the late Mr. Chauncy Puzey by the Rev. J. Bell-Cox, who, in the course of a eulogy of his old friend, paid a warm tribute to his life's work and influence. The tablet was inscribed: "To the memory of Chauncy Puzey, F.R.C.S., Surgeon and Consulting Surgeon to this Hospital 1875-1916. This tablet is erected by the committee and his colleagues in recognition of his long, valued, and devoted services. Died October 10th, 1916." Among those present were Mr. Anthony Puzey (brother), Mr. W. H. S. Oulton (vice-chairman), Mr. S. Rennie, Mr. Peter Brown, and Dr. Macfie Campbell (members of the committee), Mr. John Davidson, Colonel Rushton Parker, Professor Glynn, Dr. Caton, Dr. Nott, the Reverend R. F. Winter, Mrs. George Walker, Mrs. Jolliman, Miss Garnett, Mrs. Macfie Campbell, and Mrs. Bradshaw and Bernard.

ANNUAL MEDICAL SERVICE, LIVERPOOL.

The annual medical service for the benefit of the Royal Medical Benevolent Fund was held on Sunday afternoon, October 14th, at St. Luke's Church. There was a large congregation far outnumbering the members of the medical profession, many of whom were in military uniform. The service was conducted by the Vicar, the Rev. J. R. Darbyshire, M.A.; the Bishop of the Diocese, the Right Reverend Francis J. Chavasse, read the lesson and pronounced the benediction, and the Very Reverend H. Henley Henson, D.D., Dean of Durham, preached the sermon, and took for his text, "He endured as seeing Him who is invisible" (Hebrews xi, 27). Dr. Henley Henson set forth the lofty

ideals which permeated the Red Cross in its ministering capacity in the war. He contrasted in moving language the two great streams of tendency which had coursed through centuries side by side in opposite directions, and now in this world-war had dashed against each other in conflict—the one characterized by advancing human life, rising ever towards high ideals, the other seizing with malignant skill the products of man's ingenuity to impose on humanity the soul-killing idea of might. The preacher emphasized this dualism in history, not only of mankind, but existing in individual man. It was the duty of his profession, as of the medical profession and the ancillary vocations, ever to preserve the high aspirations set forth in the text. The Dean paid a touching tribute to all branches of the combatant and healing forces of the country; the service and sacrifice given amid terrors despised and risks unnumbered were among the inestimable riches acquired in the darkest hours, and would ever remain an imperishable heritage of moral greatness. The committee which arranged the service deserve the thanks of the profession for the opportunity of listening to so gifted a preacher. It is a matter of regret that there was no opportunity of meeting Dr. Henley Henson and the clergy of the city, as on a former occasion at the Liverpool Medical Institution, after the service. It is to be hoped that the committee will endeavour to repeat such a meeting. The offertory amounted to £48, which is considerably above the average, and it is expected that this amount will be forwarded intact without deduction for the incidental expenses to which those members who were unable to be present would doubtless wish to contribute. Mr. R. J. Hamilton, 82, Rodney Street, is the honorary treasurer.

CENTRAL MIDWIVES BOARD.

At a meeting of the Central Midwives Board on October 11th, when Sir Francis Champneys was in the chair, the proposals of the Association for Promoting the Training and Supply of Midwives for a State-aided midwifery service in England and Wales were considered. The proposals had been submitted to the Home Secretary, and had been referred to the Board by the Privy Council. The Board agreed to inform the Privy Council that while reserving its opinion on its financial aspects, it gave its general approval to the scheme. A communication was received from the Scottish Central Midwives Board calling attention to the following statement in the report of the Departmental Committee on the welfare of the blind:

The Central Midwives Board have deleted from the instructions certain parts of the treatment known as the *Crédé* method, which method is known to have led to a large reduction in cases of ophthalmia neonatorum. We are of opinion that this should receive immediate attention.

The Central Midwives Board agreed to reply that the statement in the paragraph quoted was incorrect; in view of the fact that medical opinion on the value of the *Crédé* treatment was not unanimous the Board had from the outset carefully abstained from prescribing the use of that method or any other specific treatment of the eyes of the newly born infant. The Chairman reported on the results of the inspection of eighteen training schools and institutions in the London area conducted by midwives approved for the purpose. At a meeting on the previous day four women were struck off the roll for general incompetence, one was censured, and in two other cases judgement was suspended for reports in three and six months respectively.

Scotland.

SHORTLY after the death of Dr. J. Munro Campbell, a well-known practitioner in the southern suburbs of Glasgow, a committee was formed to raise £100 to name a bed in the Samaritan Hospital, to which he was one of the visiting surgeons. Subscriptions received from 600 persons amount to £373, and it has been determined not only to name a bed but to found a bursary for children at the Pollok Academy and the Sir John Maxwell School, Pollokshaws, and to place a medallion on a public building in Pollokshaws and a marble slab on the grave.

At a meeting of the Midlothian County Council last week it was decided to vote £300 towards the scheme

desired by the Board of Agriculture for the destruction of rats, provided the Board refunded £100. The damage done to grain has been so considerable during the last few years that the Secretary for Scotland has stated that a reasonable contribution towards the expenditure might be made by the Board under certain conditions, but that it was expected that agricultural and commercial interests concerned would contribute liberally.

REPORT OF THE ROYAL COMMISSION ON HOUSING.

In 1909 the Scottish Miners' Federation had an interview with the then Secretary for Scotland as to the defects in the housing accommodation available in some of the colliery districts. Subsequently the Local Government Board for Scotland obtained reports from county medical officers of health, and after further interviews between the Secretary for Scotland, the Scottish Miners' Federation, and Scottish members of Parliament, a Royal Commission was appointed on October 30th, 1912. It has now presented its report, which is the more voluminous because, although all the members of the Commission are agreed as to the nature and extent of the evils, there is a difference of opinion as to the remedies which can best and most quickly be applied. The main report is signed by eight members and the minority report by four. The broad results of their survey, which has extended to the whole of Scotland, are summed up by the Commissioners in the following paragraphs:

Unsatisfactory sites of houses and villages, insufficient supplies of water, unsatisfactory provision for drainage, grossly inadequate provision for the removal of refuse, widespread absence of decent sanitary conveniences, the persistence of the unspeakably filthy privy-midden in many of the mining areas, badly constructed, incurably damp labourers' cottages on farms, whole townships unfit for human occupation in the crofting counties and islands, primitive and casual provision for many of the seasonal workers, gross overcrowding and huddling of the sexes together in the congested industrial villages and towns, occupation of one-room houses by large families, groups of lightless and unventilated houses in the older burghs, clotted masses of slums in the great cities. To these add the special problems symbolized by the farmed-out houses, the model lodging-houses, congested back-lands, and ancient closes. To these, again, add the cottages a hundred years old in some of the rural villages, ramshackle brick survivals of the mining outbursts of seventy years ago in the mining fields, monotonous miners' rows flung down without a vestige of town plan or any effort to secure modern conditions of sanitation, ill-planned houses that must become slums in a few years, old houses converted without necessary sanitary appliances and proper adaptation into tenements for many families, thus intensifying existing evils, streets of new tenements in the towns developed with the minimum of regard for amenity. The last census showed that thousands of one-room houses continue to be occupied by families; that overcrowding, reckoned even by the most moderate standard, is practically universal in the one- and two-room houses; that, in spite of protest and administrative superintendence, domestic overcrowding of houses and overbuilding of areas have not been prevented.

To our amazement we found that even if we take overcrowding to mean more than three persons per room, we should, to secure even this moderate standard for Scotland, have to displace some 284,000 of the population. But this is not all. We conclude that at least 50 per cent. of the one-room houses and 15 per cent. of the two-room houses ought to be replaced by new houses. In brief, merely to relieve existing overcrowding, and replace houses that should be demolished, some 121,000 houses are required, and if an improved standard is adopted, as we recommend, the total number of new houses required would approach 236,000. For such gigantic figures our report submits full justification. It is only now that the nation has had the means of discovering how far Scotland has been left behind, and by what poor standards the housing of her working classes has been measured. Our report, and the evidence it rests upon, will carry conviction to every disinterested person.

Reference to the remedies proposed and the nature of the difference of opinion on this head must be deferred.

Ireland.

DR. FITZGERALD, who has been medical officer of the Newtownbutler district for the past forty years, has just recovered from a severe illness; the people of the district, to mark the high esteem in which he is held, presented

him with an illuminated address and a cheque for £350, and Mrs. Fitzgerald with a gold wrist watch.

THE LOCAL GOVERNMENT BOARD.

The Gorey Guardians, who have been for six weeks on strike as a protest against the order of the Local Government Board enforcing the Vaccination Acts, have been notified that, if they fail to meet on Saturday next the Board will be dissolved on the following Monday and the conduct of business entrusted to paid officers. The Wexford Guardians, who had alleged that they were unable to find a substitute for the medical officer for one of their dispensary districts, except a doctor of military age, have yielded to the suggestion of the Local Government Board to appoint a woman doctor to act as substitute.

Correspondence.

REFRESHMENT HOUSE EXPERIMENTS IN CARLISLE.

SIR,—From time to time I have forwarded to you particulars with regard to the State control of the liquor traffic in this city, and in a letter to the JOURNAL published on June 9th last I gave you a brief summary of the results which had been obtained. At the same time I gave you the record of convictions for drunkenness for the first five months of this year as compared with the corresponding period of 1916. Since then there has been a steady decrease of convictions for drunkenness, as the following table will show:

Year.	July.	August.	September.	Total.
1916	91	46	62	199
1917	14	20	14	48
Decrease	77	26	48	151

The totals for the first three quarters of 1916 were 763, and for the corresponding periods of 1917 were 277, a decrease of 486. The convictions for assaults on the police during the same periods in 1916 were 33 and in 1917 they were 15, a decrease of 18. The prohibition of the sale of spirits on Saturdays continues to have a very beneficial effect. It should be stated that there has been a change in the population during the present year, the rough element engaged in construction work having disappeared, but, making due allowance for this, it must be obvious that there has been a great advantage in the restrictions that have been imposed on the community. With the opening of the Citadel Tavern this week the scheme of the Control Board's (Liquor Traffic) reconstruction programme in Carlisle has been completed, and they may now claim that they are providing for the needs of every class of the community in respects of meals and refreshments. The Citadel Tavern is the only house under the Board's management in Carlisle in which meals costing more than 1s. 3d. for food only will be served. It has been formed out of the reconstruction of the premises of the Wellington Hotel and the Three Crowns Inn. The premises have been converted into a handsome dining room, lounge, café, and restaurant. There will be a table d'hôte luncheon on weekdays from 12 to 2.30 at 1s. 6d. per head, including soup, entrée or joint, sweet or cheese, and a cup of tea or coffee. Each evening dinner will be served from 6 to 8 o'clock at 2s. 6d. per head, the menu being soup, fish, entrée or joint, sweets, and cheese. Refreshments will be served also *à la carte*. There are now seven taverns in different parts of the city, and at three of them arrangements have been made for the "off" sale of food. This arrangement is to some extent on the lines of the communal kitchen, and the view taken by the board is that if the poor people availed themselves more widely of the facilities provided for them under the new régime it would be greatly to their advantage. This development is being closely watched, and at a later date I propose to send you details showing how far it has succeeded.—I am, etc.,

Carlisle, Oct. 16th.

HENRY BARNES, M.D.

DYSENTERY AT GALLIPOLI.

SIR,—The letters from Captains Bahr and Bartlett, R.A.M.C., on dysentery at Gallipoli, which appeared in your issue of September 22nd, were of considerable interest to me.

I had an opportunity of studying the epidemic in question from the clinical aspect at Mudros and Suvla Bay during July and August, 1915, and later from the bacteriological aspect at the Central Laboratory, Alexandria. My conclusions were embodied in a paper which appeared in October, 1916. I am in complete agreement with Captain Bartlett that the large majority of the cases were of amoebic origin. This belief was supported by the clinical features characterizing the cases with which I came in contact, the response to emetine treatment, the findings during microscopical and cultural examination of the stools, the results of serological tests, and the appearance presented by the intestines of fatal cases.

Clinical Features.—All cases occurring amongst the men under my charge were characterized by the insidious apyrexial onset supposed to be characteristic of amoebic dysentery. Symptoms of severe diarrhoea with abdominal pain heralded the onset, and it was not for twenty-four to forty-eight hours or later that the patient, frightened by the appearance of blood in his motions or compelled by the increasing severity of the symptoms, reported sick.

Response to Emetine.—During the early stages of the epidemic the patients rarely received emetine until their arrival at the base, and during this period the cases admitted to hospital in Egypt were very severe, showing as a rule abundant blood and mucus in the stools. Later, when emetine was injected at the field ambulances and stationary hospitals, the type of case coming under our observation at the base was certainly much less severe. Many showed no blood in the stools and some were convalescent.

Examination of Stools and Serological Tests.—In my series of cases 12 per cent. were shown to be pure amoebic infections, in 7.6 per cent. dysentery bacilli were isolated, and in 2.6 per cent. both *E. histolytica* and dysentery bacilli were found. Therefore, of the positive cases, the amoebic far outnumbered the bacillary.

How can the failure to detect the causative agent in such a large number (over 70 per cent.) of cases be explained? Was it due to incomplete examination or to disappearance of the latter previous to the time of examination? The greater number of negative cases in this series were examined on several occasions, so that I do not believe that any considerable error was introduced owing to incomplete examination. The conclusion reached was that the majority of these cases were entamoebic in origin, the entamoebae having disappeared from the stools as the result of emetine treatment.

This view was supported by the fact that serological tests carried out during December, 1915, and January, 1916—months during which amoebic dysentery was presumably reaching its ebb—resulted in only 30 per cent. being shown to be of bacillary nature. Therefore even at this period of the year the amoebic cases outnumbered the bacillary.

Appearance of Intestines.—Evidence of the amoebic nature of the lesions is afforded by the appearance of isolated nodular projection and flask-shaped ulcers separated by normal mucous membrane. This appearance is only presented by the intestine in the early stages of the disease as secondary bacterial invasion of the ulcers soon alters the appearances, and gives rise to the picture of a more or less diffuse inflammation, with numerous irregularly shaped ulcers. In an advanced case of the disease, therefore, the amoebic origin of the lesions can only be proved by microscopical demonstration of the parasite in the intestinal wall.

In this regard I may mention that the amoeba-like appearance presented by certain phagocytic and vacuolated cells, alluded to by Captain Bahr, was well recognized, and reference was made to them in the paper previously mentioned.¹

I was privileged to attend a large number of *post-mortem* examinations carried out by Captain Bartlett on fatal cases of dysentery, and of these the large majority showed, either to the naked eye or microscopically, typical amoebic

lesions. Details will be found in Captain Bartlett's own paper on this subject.²—I am, etc.,

W. MAGNER, ex-Lieutenant R.A.M.C.,
Pathology Department, University College, Cork.

September 28th.

RUPTURE OF UTERUS.

SIR,—Dr. H. Davies-Jones's concluding sentence in his letter on the above subject in your issue of September 22nd should be sufficient to warn off most of us; but I mean, with your permission, in all diffidence, to enter the arena.

First, I desire to add my congratulations to Dr. Rigden on the eventual recovery of his patient, though childless and without her uterus.³ The history and Dr. Rigden's statement show us that it was a case of flat pelvis, though to what extent of contraction we are not informed, nor, what is equally important, do we know the disproportion between child and pelvis, which cannot be estimated without some data as to weight of child as well. What a text for the advocates of antenatal treatment this case affords! And, in passing, one may note that according to the new rules of the Central Midwives Board, 1916, the midwife erred in not advising her patient to have medical advice before labour.

The important decision as to immediate turning, or, alternatively, the application of forceps in flat pelvis, depends largely on an unfavourable or favourable position of the head respectively, but, personally, the forceps in nearly all cases is my choice. Probably the most salient point in this remarkable case for comment and our guidance to treatment is the fact that there was *no pulsation* of the umbilical cord, consequently, the child being dead, immediate perforation, and embryotomy if necessary for easy extraction, was indicated.

I do not think it fair for any one not present at the case to comment on the subsequent surgical treatment, but I think it is arguable that the immediate removal of the placenta per vaginam might have saved the abdominal section, bearing in mind in this connexion that figures of mortality after uterine rupture by themselves are insufficient to decide the relative claims of plugging and drainage as against immediate abdominal section.—I am, etc.,

Norwich, Sept. 24th.

ARTHUR CROOK.

RECURRENCE OF ADENOIDS AND TONSILS.

SIR,—It is one's common experience to examine children whose respiratory deficiency is undoubtedly due in the first instance to a deflected septum, with the usual turbinate deformity. Very frequently there is a history of operation for removal of tonsils and adenoids, with, naturally, poor results, as judged by the unaltered mouth breathing and unchecked facial deformity. Heredity plays a very prominent part, with the result that "asthma in the family" may often be interpreted as inherited nasal deformity; and unfortunately, so far, very little can be done in children to remedy this abnormality, with its usual resulting train of signs and symptoms.

A few days ago I became possessed of a remarkably well-preserved skull, recently unearthed on the site of the Roman settlement of Caerwent. There is well-marked septum and turbinate deformity, and the usual alteration in the palate, antrum, etc. General skull shape, facial angle, and well-formed nasal bones presume a male Roman.—I am, etc.,

Newport (Mon.), Oct. 6th.

J. LEWIS THOMAS.

TREATMENT OF ACUTE GONORRHOEA.

SIR,—The article by Captain Lumb, R.A.M.C., in the BRITISH MEDICAL JOURNAL, October 6th, 1917, calls for some comment, since the electrical process he used is described as similar to my method. I must point out that he made deviations from my method, and these doubtless affected his results. First, Captain Lumb has employed a silver catheter, and he must surely be aware that during electrolysis this instrument is being dissolved, and silver ions are being driven into the lining of the urethra. He has, therefore, been treating these cases by silver ionization—a process I have never described or recommended. The second important variation is an arrangement of an

¹ Some Observations on Dysentery, *Lancet*, October 21st, 1916.

² *Quarterly Journal of Medicine*, April, 1917.

³ BRITISH MEDICAL JOURNAL, September 1st, 1917, p. 289.

in-and-out flow of a liquid under pressure to produce distension of the urethra by the contained liquid. This is a procedure I have never practised, as I believe it to be harmful; my reasons have been given in the *BRITISH MEDICAL JOURNAL*, May 12th, 1917.—I am, etc.,

London, W., Oct. 12th.

CHARLES RUSS.

THE SUPPLY OF MORPHINE, ETC., TO ARMY MEDICAL OFFICERS.

SIR,—May I point out that Dr. William Martin (September 29th, p. 439) is evidently referring in his letter to the Regulations Nos. 40, 40A, and 40B, issued under the Defence of the Realm Act? The order referred to by the *Pharmaceutical Journal*, however, is that issued by the Army Council, dated May 11th, 1916, which prohibits the sale or supply of the drugs specified in those regulations, or of any preparations, derivatives, or admixtures prepared therewith or therefrom, to or for any member of His Majesty's forces without written prescription in the specified form.

The effect of this order as interpreted by the *Pharmaceutical Journal*—and the interpretation seems to have received some form of endorsement from the War Office—prohibits the supply of any of these drugs to any medical practitioner who is a member of His Majesty's forces, whether he requires these drugs for his private practice or not. The order is thus another instance of hastily promulgated decrees, the effect of which is, as Dr. Martin says, an intolerably unfair restriction on the legitimate freedom of action of medical practitioners.—I am, etc.,

October 4th.

PHARMACIST.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—I was very pleased to see Dr. Dewar's letter in your issue of October 6th, p. 467. The Insurance Acts Committee did the profession a distinct service when they persuaded the Commission to release it from the trouble of keeping the record card. I have never seen any letters of thanks and yet the Insurance Acts Committee is ever working on behalf of the panel practitioners. The extremist is the man who rushes into print. Why does not the moderate medical man write oftener and express his views? Dr. Brackenbury is doing a great service to the profession, but the moderates must be up and doing and give him every support, or the extremists will get their own way, and then, indeed, there will be a crisis in the profession. The conference on the 18th is fraught with great dangers. I hear of impossible demands. We must remember there is a very strong section of lay extremists in the country doing all they can to persuade the Government to scrap the present panel system and start a whole-time salaried service. There is also, I believe, a stronger section still in favour of the panel system. If the profession is coerced to support extreme demands, they will only force the moderate section who are still in favour of the panel system to go over to the extremists, and a whole-time State medical service will be forced on the profession.—I am, etc.,

Birmingham, Oct. 9th.

F. A. L. BURGESS.

SIR,—It is high time that rural practitioners should protest against the terms offered them for attending discharged soldiers. For going three miles (the last half mile or more of which they may have to walk through mud and snow) to see a patient they are to be paid half a crown, no more than the town doctor is paid for seeing his patient next door or in the same street. Such terms are quite impossible at the present day. The same injustice is done with regard to attending temporary residents, and I am surprised rural practitioners have put up with that arrangement. We are told that there were no data at hand to enable an accurate computation to be come to, but surely no datum but common sense is necessary to show the manifest unfairness in the treatment of the country doctor. I see one "leader" of our profession tries to excuse the small fee offered by saying that if we make a good many attendances at even a small fee, the whole will amount to quite a considerable sum. Surely this is the most pernicious stuff ever written—the argument of the cheap-jack.—I am, etc.,

October 15th.

RUS IN URBE.

PANEL PRACTICE AND REMUNERATION FOR DRUGS AND MILEAGE.

SIR,—I am glad to see "Old October's" letter (October 13th, p. 498). Surely panel practitioners cannot be satisfied with the present state of affairs. For those who dispense and also have long journeys; the enormous increase in the cost of drugs, petrol, and various other necessities has brought the actual remuneration down to an extremely small figure.

In my own case, though my panel list has gradually increased, my pay has decreased since the early days of the Act. I believe the figures have been as follows:

	1913.	1914.	1915.	1916.
Average numbers on list, all of whom are dispensed for	232	246	265	281
Remuneration, including dispensing, but excluding temporary residents	£ s. d. 112 12 1	£ s. d. 103 19 6	£ s. d. 107 0 10	£ s. d. 105 3 10

Even if these rates have been correct according to the strictly legal interpretation of the Act, they certainly prove that we can have no idea whatever until the end of the financial year, or rather until the final instalment is paid, what we are entitled to receive.

What would the ordinary man in the street who is receiving a war bonus on account of extra cost of living say to such figures? Our professional brethren who are not panel practitioners but salaried officers of various kinds have in many instances, no doubt deservedly, received war bonuses on account of extra expense, though these may simply apply to cost of living. Are we, with the hugely increased expenses thrust upon us since 1913, not equally deserving? Inflation or no inflation, I have no hesitation in saying that my work has very considerably increased.

"Old October" appears to make a very moderate demand when he suggests that this obsolete scale (which few understand and none can check should be "revised and adjusted to meet these increased costs." The justice of this suggestion applies, I imagine, most especially to country practitioners, on whom fall most heavily the extra costs of drugs, petrol, and other motoring necessities.

In any possible new arrangement it should be a *sine qua non* that the terms stated should be only capable of one meaning, should require no explanatory statement, and should be such as to enable each panel practitioner to know how much was due to him. In no other way can we judge as to whether the game is worth the candle.—I am, etc.,

West End, Hants, Oct. 15th.

C. H. POWERS.

THE AIR WAR.

SIR,—I see that in your issue for October 13th a territorial medical officer objects to your suggesting or having given currency to a statement to the effect that the bombing of a certain base hospital was intentional. It is superfluous for this officer or any other well-wisher of the allied cause to take upon his shoulders the task of excusing the Germans. It is not a question of defending interests of eternal truth, for on both sides nothing but suppositions are involved. You suppose the bombing was intentional, he supposes it was not. I believe myself that the probabilities are in your favour. The number of hospitals bombed at the front is indicated by the number of deaths and injuries of nurses recorded. The hospitals concerned have lain in more than one case at a considerable distance from any legitimate object, and a hospital camp is of such a character that no Taube can well fail to recognize what it is.—I am, etc.,

France, Oct. 15th.

UNBIASED.

As a war measure a limited number of women are to be admitted to the course of Harvard Medical School this year. They will not, however, be eligible for any medical degree.

The Mayo Foundation has become the absolute property of the University of Minnesota. The fund is to be used for higher medical education, research, and investigation. The expenses of the foundation will be defrayed by Drs. Charles H. and William J. Mayo till a fund of £400,000 has been accumulated; afterwards the income from the fund will suffice to maintain the foundation.

The Services.

EXCHANGE.

LIEUTENANT R.A.M.C., who has served a year in France at a base hospital, desires an exchange for the winter months with a medical officer in England.—Address, No. 3603, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.2

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

The following candidates have satisfied the examiners in both parts of the examination in Sanitary Science: Captain A. J. Gibson, R.A.M.C., Captain G. B. Mason, R.A.M.C., D. Wainwright.

UNIVERSITY OF LONDON.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

MR. R. H. O. B. ROBINSON has been awarded the University Scholarship of £50. He is the son of Mr. Betham Robinson, surgeon to the hospital.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.

The following scholarships, medals, and prizes have been awarded during the session 1916-17:

Entrance Scholarships: H. B. Shaw (first), E. B. Dancy (second), J. Whitby (third). Broderip Scholarships: R. E. S. Webb (first); second not awarded. Lyell Medal and Scholarship: S. C. Shaw. Freeman Scholarship: S. C. Shaw. Hetley Clinical Prize: R. E. S. Webb. Second Year's Exhibition: O. S. Hillman.

UNIVERSITY OF EDINBURGH.

GRADUATION CEREMONY.

A GRADUATION ceremony was held in the McEwan Hall on October 12th, when the degree of Bachelor of Science in the Department of Veterinary Science was conferred for the first time. The principal, Sir Alfred Ewing, in a short address after the ceremony, said that notwithstanding the preoccupations of war and the difficulty of meeting its claims and sustaining its losses the need for new developments had not been forgotten and definite progress had been made in more than one department. Satisfactory arrangements had now been made to give to women in medical classes the same privileges as men in respect of clinical as well as academic instruction. A professorship of tuberculosis and allied diseases had been instituted, and in Sir Robert Philip the university had received an accession to its medical staff which would bring additional lustre to the school. Steps had been taken to divide the subject of chemistry among three more professors—of general chemistry, of chemistry in relation to medicine, and of technical chemistry. The initial steps for the establishment of chairs in French language and literature and German language and literature, and lectureships in Spanish and Italian languages had been taken.

The following degrees were conferred:

M.B., CH.B.—D. Chanis, H. C. Elder, R. N. Mackenzie, Ikbal Singh, Naiwa, A. J. Pollock, J. H. Sypkens, A. Ba Thaw, J. Thompson, K. L. S. Ward.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

A MEETING of Fellows and Members will be held at the College, Lincoln's Inn Fields, on Thursday, November 15th, at 3 p.m., when a report, copies of which can be obtained by Fellows and Members on application to the Secretary, will be laid before the meeting. Notices of motion must be received by the Secretary not later than November 6th. On and after November 13th a printed copy of the agenda will be issued to any Fellow or Member who may apply for one.

The honorary secretary of the Society of Members, Dr. Sidney C. Lawrence, informs us that the society addressed a letter to the Council of the College respectfully suggesting that in view of the present great pressure on the time and money of medical men at home and the absence of so many Members abroad on His Majesty's Service the annual meeting of Fellows and Members should not be held. In taking this step the Society reserved its right to advocate the cause of the Members on future suitable occasions. Dr. Lawrence adds that the Society regrets the decision of the Council to hold the meeting, as many Members will be unable to attend, and the expenses associated with the meeting might have been saved to the College funds.

CALENDAR.

The *Calendar of the Royal College of Surgeons of England for 1917*,¹ just issued, contains the customary historical and formal information, together with lists of Fellows, Members, Licentiates, and Diplomates, reports of proceedings, and financial statement. A short account is given of the work of the Committee of Reference, which during the year ending July, 1917, held fifty-two meetings. Professor Arthur Keith, in his report as Conservator of the Museum, states that the measures taken to safeguard its contents against aerial attack have not been in

any way relaxed. Until the conclusion of peace it is unlikely that preparations will be restored to their proper places in the Museum, but it should be understood that although the Museum is closed to ordinary visitors, its contents are made accessible to those who wish to carry on research or to make a study of a particular series of specimens or preparations. During the past three years the depleted staff of the Museum has been increasingly occupied with the War Office collection, and at the present time this work monopolizes the time and energy of all concerned.

COUNCIL MEETING.

An ordinary quarterly council was held on October 11th, when Sir George Makins, President, was in the chair.

Leave of Absence.

Leave of absence was granted to the President for three months, and to Sir Berkeley Moynihan for October and November, both during absence abroad on Government duties.

Catalogue of Surgical Instruments.

The thanks of the Council were given to Mr. Alban Doran for his services in continuing to arrange and catalogue the collection of surgical instruments in the museum.

University of Liverpool.

Sir George Makins was appointed a member of the Court of the University of Liverpool for three years from January 1st, 1918, the late Sir Frederic Eve having been the last so appointed.

Obituary.

DEPUTY SURGEON-GENERAL WILLIAM CHERRY, R.A.M.C. (ret.), late of New Ross, Ireland, died at Bournemouth on September 21st. He took the diplomas of L.K.Q.C.P. and L.R.C.S.I. in 1859, and entered the Army Medical Department as assistant surgeon on January 19th, 1860, becoming surgeon in January, 1872, surgeon-major on March 1st, 1873, and retiring as brigade surgeon, with an honorary step, on March 28th, 1887.

DEPUTY INSPECTOR-GENERAL WILLIAM HENRY PATTERSON, R.N. (ret.), died after a long illness on October 4th, aged 67. He was educated at the Ledwich School, Dublin, and took the diplomas of L.R.C.S.I. and L.K.Q.C.P. in 1871. Entering the navy soon after qualifying, he attained the rank of fleet surgeon on December 9th, 1890, and retired with an honorary step of rank on September 26th, 1905.

COLONEL JAMES HYSLOP, D.S.O., Deputy Director of Medical Services, Union of South Africa, died at the Sanatorium, Pietermaritzburg, Natal, on October 5th, at the age of 60. He was the son of the late Thomas Hyslop of Woodpark, Kirkeudbright, and was educated at Edinburgh University, where he graduated M.B. and C.M. in 1879, afterwards studying at Berlin, Vienna, and Munich. For the past thirty years he had been Superintendent of the Natal Government Asylum at Pietermaritzburg; he was also President of the Natal Medical Council. He served in the South African war, gaining the medal and the D.S.O., and again in the suppression of the Natal Native Rebellion in 1906. He was for some years Principal Medical Officer of the Natal Militia. In 1899 he represented the Natal Government at the South African conference on plague, and acted as chairman of the plague conference at Durban.

DR. LEWIS A. STIMSON of New York, who died suddenly in September, was born at Paterson, New Jersey, in 1844. He graduated in arts at Yale in 1863, and served as a captain in the Union army till the end of the Civil War. He was professor of physiology from 1883 to 1885, of anatomy from 1885 to 1889, and of surgery from 1889 to 1898 in the New York University Medical College. In 1898 he was called to the chair of surgery in the Cornell Medical College, New York City. Dr. Stimson was consulting surgeon to the New York and Bellevue Hospitals, and his name was well known to surgeons throughout the world by his work on operative surgery published in 1900 and his *Treatise on Fractures and Dislocations*, which has gone through eight editions. He was also the author of numerous other contributions to medical literature. He was an enthusiastic yachtsman, and some years ago sailed his own boat in a race across the Atlantic.

¹ London: Taylor and Francis, 1917. (Demy 8vo, pp. 502. 1s.)

Medical News.

THE scientific meetings of the Zoological Society of London will be resumed at the house of the society, Regent's Park, on Tuesday next, October 23rd, at 5.30 p.m.

DR. PRESTON KING has been nominated as mayor of Bath for the ensuing year, and Dr. James Pearson as mayor of Bootle. Both have previously held the office of mayor.

DR. JOHN DIVINE of Hull, lately a member of the Insurance Acts Committee of the British Medical Association, has been added to the Commission of the Peace for the city of Hull.

MR. ALEXANDER ADAIR ROCHE, K.C., who has been appointed one of the Justices of the High Court in the King's Bench Division, is the son of Dr. William Roche, who formerly practised at Ipswich and now, we believe, resides in retirement at Honiton.

A JAPANESE medical corps of one hundred men has gone to Rumania to help in the effort to control the epidemic of typhus fever in that country. The corps is divided into three sections—internal diseases, surgery, and epidemics—each with its own chief. The head quarters of the corps will be at Jassy.

THE Minister of Pensions has received from a Manchester gentleman, who wishes to remain anonymous, an offer to subscribe £50,000 towards the cost of institutional treatment for disabled sailors and soldiers. Half of the American Red Cross gift of £200,000 to the British Red Cross is to be devoted to institutions for orthopaedic and facial treatment and for general restorative work for disabled British soldiers.

AT the next meeting of the Medical Society of London, to be held on Monday, October 22nd, at 8.30 p.m., at 11, Chandos Street, Cavendish Square, W.1. Mr. Muirhead Little and Major R. C. Elmslie, R.A.M.C.(T.) will introduce a discussion on modern artificial limbs and their influence upon methods of amputation. There will be a practical demonstration with patients and appliances. Colonial and American medical men on active service will be welcomed at the meeting.

A MEETING of the Royal Sanitary Institute will be held in Newcastle on Friday and Saturday, November 9th and 10th. On Friday, at 7 p.m., a discussion on "Standards of meat inspection under war time and other conditions" will be opened by Mr. Thomas Parker, F.R.C.V.S., veterinary officer and inspector of provisions, Newcastle. On Saturday morning (10.30) Mr. John H. Mole, sanitary inspector and surveyor, Chester-le-Street R.D.C., will open a discussion, illustrated by an exhibit of building materials, on "Structure in municipal housing." On Saturday afternoon a visit will be paid to Elisabethville, a Belgian village where the buildings are of both temporary and permanent types, in order to inspect the planning and structure adopted.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the British Medical Journal are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

THE address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

RHEUMATIC CRIPPLES.

SEVERAL correspondents have asked us recently for assistance in finding homes for persons suffering from rheumatoid arthritis or chronic rheumatism, only able to pay a small sum weekly. It appears that at the present time some such homes are occupied for military purposes. If any member is able to assist we shall be happy to publish the information or forward it to our correspondents.

LETTERS, NOTES, ETC.

COFFEE AND TEA.

THE difficulty recently experienced in getting tea, greater in some districts than in others, has probably disconcerted British housekeepers more than any of the shortages they have experienced during the last year. Some grocers have refused to serve to any one customer more than a quarter of a pound, which is the weekly ration of the British soldier in France. He no doubt likes his tea strong, but even so the ration is liberal, for half an ounce of tea is reckoned to make six cups, probably much more than he would have consumed at home. Large War Office purchases may account for the present shortage, but as the total consumption of tea in the United Kingdom is estimated to be about three-hundred million pounds a year the twenty-six millions a year required for the British armies in France ought not to cause any permanent dislocation of the trade, and it is believed that the situation will soon be relieved by new arrivals. The comparative neglect of coffee in this country is probably due to ignorance of how it should be made, although the greater palatability of a cup of coffee made from the bean recently roasted and ground may have something to do with it. The common fault, however, is to treat the ground coffee in the same way as tea and to make much too weak an infusion. Two ounces of coffee to a pint of water is probably a proper proportion, and, according to Hutchison, a teaspoonful of such coffee will contain very much the same amount of caffeine and tannic acid as an equal quantity of tea. It should be noted that caffeine in coffee is combined with a peculiar acid, allied possibly to tannic acid, but exhibiting different properties from the tannin present in tea. This "caffetannic acid" is not particularly astringent. Further, according to the investigations of the *Lancet*, whereas the caffeine tannate of tea is precipitated by weak acids and therefore probably by the gastric juice, so that the caffeine is not absorbed until it reaches the alkaline alimentary tract, in the case of coffee the caffeine is soluble in both alkaline and acid fluids, so that the absorption of the alkaloid probably takes place in the stomach. This may explain the opinion generally accepted that coffee is a more powerful and rapid restorative than tea. A breakfastcup of *caffetannic acid* is composed of about one part of black coffee to three of milk and will not contain more alkaloid than a teaspoonful of tea.

SHORTAGE OF MEDICAL STUDENTS AND THE MILITARY AGE.

A CORRESPONDENT writes with reference to the article on the shortage of medical students published in our issue of September 29th, p. 428, to express the opinion that the age limits for military service in the American army, namely, not less than 21 years and extending to 45 years, are more correct scientifically considered than those hitherto applied in this country, and continues: Boys of 18 years of age, if healthy, are generally high spirited, active, and fond of adventure, but from a medical point of view are not sufficiently developed, in most instances, to withstand the strain of either military training or active service, owing to their organs being not fully developed and the bones of the arms and legs not completely ossified. This is an anatomical fact and has had due weight with the Americans. Neither have boys of 18 the calculating steadiness of the man of 21 years upwards. At this stage of the war, then, it does not appear to me to be at all necessary to continue taking boys of age of 18 years away from their studies. By all means let these youths go on with their civil studies or training until they are 21 years of age, and organs, bones, and mind fully developed. Compulsion up to 45 or 47 years of age is certainly better. The military age should be raised from both ends of the scale. Another point respecting boys is that the compulsory calling up of an only boy, who is also an only child, ought not to be enforced, as by so doing there is the risk of exterminating (by compulsion) the family line.

TREATMENT OF SCABIES.

DR. R. HOGARTH CLAY (Plymouth) writes: I have never failed to cure scabies by using a bath containing 3 ounces of potassium sulphuret in as much water as will entirely cover the patient, who should remain immersed up to his neck, with hands and arms under water for twenty minutes. The bath should be of comfortable warmth, and of course all underclothing must be disinfected.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postae restante* letters addressed either in initials or numbers.

The Harveian Oration

ON

HARVEY'S WORK CONSIDERED IN RELATION TO SCIENTIFIC KNOWLEDGE AND UNI- VERSITY EDUCATION IN HIS TIME.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON ON OCTOBER 18TH, 1917.

BY

ROBERT SAUNDBY, M.D., F.R.C.P., M.Sc., LL.D.,

EX-PROFESSOR OF MEDICINE, UNIVERSITY OF BIRMINGHAM; CON-
SULTING PHYSICIAN, BIRMINGHAM GENERAL HOSPITAL.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN,—In the first place I have to thank you, Sir, for entrusting me with the most honourable duty of delivering the annual oration founded by our greatest associate, Dr. William Harvey, the supreme glory of our College, whose memory we all cherish and whose work is universally regarded as the peculiar pride of English medicine. In founding this oration he enjoined in the deed of gift that the orator should exhort the Fellows of the College to search out and study the secrets of nature by way of experiment, and for the honour of the profession to continue in mutual love and affection among themselves. It was also his wish that on this occasion should be commemorated those benefactors of the College who by gifts or by their contributions to medical knowledge have forwarded the interests of this College in the course of the bygone year.

RECOGNITION OF HARVEY'S WORK.

Harvey's work has been justly regarded as remarkable by its great success in his own lifetime, and especially in his own country and among his colleagues in this College, where there appear to have been no discordant voices. So far from it being true, as a recent British writer has ventured to say, that the only criticisms on his work were heard from his fellow-countrymen, the very contrary is the truth, and, as Willis expressly says, the appearance of Harvey's book seems almost immediately to have attracted the attention of all the better intellects among the medical men of Europe. The controversy on the circulation was carried on abroad rather than at home, for Harvey seems to have won over to his side all the men of his own country who by their education and acquirements might have been fitted to array themselves against him, and the first publication to deal with the question by one of Harvey's countrymen was that of Dr. George Ent, who undertook to defend Harvey's teaching against the criticisms of Parisanus.

A century had to elapse before the voice of criticism was heard from any British authority, and then it was the extremely able but somewhat quarrelsome anatomist Dr. William Hunter, who sought to depreciate the work of Harvey by comparing it with the discovery of America by Columbus, and the astronomical induction of Copernicus, disparaging Harvey's mental abilities on the ground of his failure to recognize the value of the discovery of the lacteals by Asellius, whose book was published about the same time as that of Harvey on the circulation of the blood (1627). William Hunter's quarrel with his glorious brother John over the placental circulation does not show him in a very amiable or even an altogether honest light; and much as we may regret that so able an anatomist should have adopted this hypercritical attitude, I think we may fairly say that his comments in no way succeeded in diminishing the glory of Harvey.

Contributions to Harveian Literature.

Successive Harveian orators have so diligently explored the somewhat scanty literary remains that throw any light upon the life and doings of our illustrious fellow-countryman, that the College warmly appreciated the address by the late President, Sir Thomas Barlow, who occupied this chair in October, 1916, and by his munificence had placed in the possession of the College certain documents, consisting of eight of Harvey's own letters written at the time when he accompanied the Earl of Arundel on an embassy to the Emperor Ferdinand. Although these letters deal with only a short episode in the life of Harvey and throw

no light whatever upon his physiological researches, they are exceedingly welcome as being contemporary accounts in his own handwriting, illustrating some at least of the difficulties that a traveller in those days met with even when forming part of the suite of a British Ambassador. It is not often that a Fellow of this College enjoys the opportunity of making a benefaction which is so closely related to the personality of Harvey, but it is possible that in the much greater attention now paid to the State papers which were so long neglected, more may be found bearing upon the life of Harvey in his position at the Court of Charles I, where he undoubtedly enjoyed the favour and the personal friendship of the King.

The College must acknowledge a valuable contribution to its Harveian literature in the publication of a memoir to recall the seventeenth century friendship of Finch and Baines, written by Dr. Malloch, a captain in the Canadian Army Medical Corps. These two graduates of Cambridge in the seventeenth century went from Cambridge to France and thence to Padua, where the professor who lectured to them on anatomy was Antonio Molinetto. Finch was a brother of Lord Nottingham, whose niece was the wife of Harvey, for whom he entertained the greatest veneration. From Padua they went to Pisa, where Finch was appointed professor of anatomy, his course of lectures including both morbid and comparative anatomy. While there he examined a live torpedo (*T. narce*) sent him by the Grand Duke of Tuscany. He describes a "pricking sensation like that which comes when you suddenly put cold fingers to the fire," on touching the fish. Later when it died he dissected it, and his report is extant; it is to be issued shortly by the Historical MSS. Commission edited by Mrs. Lomas. The friends returned to England soon after the Restoration, Baines being appointed professor of music at Gresham College, and both were unanimously elected Fellows of this College, partly no doubt on the ground of their relationship by marriage and friendship with the illustrious Harvey. On June 20th they received their degrees as Doctors of Physics at Cambridge, and in the same month the King knighted Finch, the like honour being conferred on Baines eleven years later. Finch returned to Italy and again taught anatomy at Pisa. In 1665 he was appointed the King's resident at the Court of Tuscany, and stayed there with Baines until the death of the Grand Duke in 1670. Finch was next sent to the Porte as English Ambassador, and remained in Turkey till 1681, when Sir Thomas Baines died, and Finch brought the body home; he died shortly after, according to his epitaph—"Of sorrow at the loss of Sir Thomas Baines." They were both buried in the chapel at Christ's College, Cambridge, where in memory of their friendship Finch founded two fellowships and two scholarships.

BENEFACTORS OF THE COLLEGE.

Among the great benefactors of this College whose names cannot be passed over in silence are the two Hameys, father and son; Theodore Goulston, founder of the Goulston lectures; Sir Theodore Mayerne; Dr. Richard Caldwell, who with John Lord Lumley founded the Lumleian lectureship; Lady Sadler, founder of the Croonian lectureship in memory of her first husband, Dr. William Croone; Dr. William Wood Bradshaw, founder of the Bradshaw lecture; Mrs. FitzPatrick, who founded the FitzPatrick lecture on the history of medicine in memory of her husband, Dr. Thomas FitzPatrick; and Dr. Gaviu Milroy, one of the pioneers in the subject of public health, who left £2,000 to endow a lectureship on State medicine and public health and subjects connected therewith. Further, as announced by Sir Thomas Barlow last year, there is the foundation of the Streatfeild Research Fund, endowed with £10,000 in 2½ per cent. annuities given by Mrs. Eliza Streatfeild for the purpose of the endowment of research, the fund being vested in the joint names of the two Royal Colleges, who act as its administrators.

On December 16th, 1916, the College received through our Fellow, Dr. Malins, of Birmingham, a gift of £500 from Mr. F. W. Mitchell, to be devoted to the object of the research, investigation, and treatment of tuberculosis.

On October 26th, 1916, under the will of Mrs. Fanny Hertz, of 40, Lansdowne Crescent, W., the College became possessed of a fine portrait of the late Dr. J. E. Bridges, which has been hung in the hall.

In addition valuable donations of books have been made to the library.

A CRITICISM OF HARVEY'S VIEW.

An instructive criticism of Harvey's opinions was published two years ago by the late Professor Curtis, of Columbia University.¹ In Harvey's lifetime he was often asked by his opponents to explain the purpose of the circulation, and he was never able to give a satisfactory reply. Why should the blood traverse the lungs, return to the heart, be distributed to the whole of the body, and then be brought back again to the heart in order to be transmitted again through the lungs? What did the blood gain by its passage through the lungs? Harvey taught that it was ventilated or cooled there, deriving heat from the heart, which was the centre of bodily heat. We may wonder why Harvey, following Aristotle, should regard air as cooling fire. Surely the effect of air on fire must have been known to him, and it certainly seems strange that Aristotle should have said that air keeps fire from consuming the fuel too fast. Was he not familiar with a smith's furnace, and with the manufacture of charcoal by limiting the access of air? Harvey knew that air was necessary to a candle and to fire, but did not know why. He accepted the doctrine of "spirits," an expression used by Aristotle, Erasistratus, and Galen as something derived from the air and introduced into the circulation with the blood (Erasistratus) or by itself (Aristotle).

Nearly a hundred years before Harvey's time Realdus Columbus (1559) taught that air was mixed with the blood in the lungs, where the transfer took place from the right to the left side of the heart. But this great fact that the blood in its passage through the lungs took up air was rejected by Harvey. He heads the passage: "Spirits not from Air," and he quotes an experiment to show that air does not pass into the blood, as he evidently expected to see the blood frothy if this were so.

Harvey maintained these views all his life and never understood the function of respiration, which is not surprising, as he was ignorant of the nature of combustion, of oxidation, of the corpuscular structure of the blood, and of the function of haemoglobin. He was unable to explain the difference in colour of arterial and venous blood, but he sought to minimize the importance of this by pointing out that both when drawn and allowed to stand become nearly the same colour and not of any great difference of either consistency or bulk. He knew that during life the arterial blood in the lungs was redder and that the lungs were florid. He could never explain why the fetus could live without air and yet after birth be readily suffocated by air being excluded. He always followed Aristotle in the doctrine that the heart was the primordial centre of life, and Curtis thought that Aristotle was familiar with the pulse from observing the incubating egg, where the heart makes its appearance early, and to which he consequently attributed all the chief functions of the body, including the affections, feelings, senses, and the like. Hence we still speak of the heart as the seat of emotion, of "a change of heart," "Unto Thee all hearts are opened," "Cleanse our hearts," etc. It never occurred to Harvey to inquire into the nature of the fumes given off during expiration. In Harvey's time the view was generally held that the blood is distributed to the tissues from the liver in spite of the existence of the pulmonary artery and the lungs in life being full of blood, but it is probable that medical men were blinded by the fact that after death the lungs are usually bloodless.

Harvey, moreover, was not constant in his allegiance to the heart as the centre and source of the motive power of the circulation, for as early as his lecture notes of 1616, and even in his latest utterances, he regards the blood as endowed with movement, and in his treatise on generation he asserted the primacy of the blood—"the leaping point"—the pulsating vesicle which he regarded as the first beginnings of the embryo. The blood, he says, is prior to its receptacle, the contained to its container. He maintained that the order is first the blood, second the pulsation, and third the vesicle. The blood is the "first to live and the last to die." Here, as Curtis says, Harvey was misled by his confidence in what we call naked-eye appearances and his want of better appliances. It would have been logical of Harvey had he attributed the pulse and the heart beat to the "leaping blood," but in his letter to Riolanus he says it was due to the boiling or bubbling of fermentation. He thought the swelling of the blood caused by its innate heat stimulated the auricle to contract, and he located this effect just between the openings of the

superior and inferior cavae, where we now place the bundle of His. The contraction of the auricles is, then, the cause of the contraction of the ventricles.

Curtis points out the difficulty Harvey was in owing to the backward state of physics. He was fourteen years younger than Galileo, who was unable to explain the common pump, and Harvey's discovery was made public thirteen years before Torricelli's momentous work on the movement of liquids. We must therefore recognize that many of the questions which by us are readily answered were in the days of Harvey quite insoluble, but we owe him our gratitude for the enormous advances he made with the means at his disposal.

CAMBRIDGE UNIVERSITY IN THE SIXTEENTH AND SEVENTEENTH CENTURIES.

It is of interest to inquire what were the opportunities afforded by Cambridge to the student who desired to study medicine, and how far it was possible for him to set out on the path of such learning as in those days would be regarded as at least preliminary to his studies.

The sixteenth century was not favourable to the English universities. They suffered greatly from the religious convulsions of the period. Not only were the abolition and disendowment of the religious houses causes of financial embarrassment, but sectarian considerations rather than those of character and learning were paramount in the choice of the heads of houses and professors. Religious differences could not but influence the willingness of parents to send their sons to the universities, and the resulting decline in numbers with the consequent loss of pupils' fees, impoverished the university exchequer, and such was the lowering of the standard of scholarship that the libraries were spoiled by the selling of so-called "useless" books.

The University in the Reign of Edward VI.

On the other hand, in the reign of Edward VI (1547-53) were founded the five Regius professorships in Divinity, Civil Law, Physic, Hebrew, and Greek, each being endowed with a stipend of £40, and so far as it goes we may take the professorship of physic as some evidence that the study of medicine was not altogether ignored. The first incumbent of the chair was Dr. John Blythe, of King's College, an M.D. of Ferrara, for at this time and perhaps for a century later Cambridge men had to go abroad for instruction in strictly professional subjects. John Caius left Cambridge in 1539 for Padua, where he lectured on Aristotle, in return studying "Medicine and Anatomy," which is some evidence that at Cambridge these subjects were less cultivated than Greek.

In the reign of Edward VI the university attracted many students, of whom too many were absorbed in theological controversy (Ascham); moreover, it was complained that the majority were mere boys, the sons of wealthy parents, who never became serious students, but by their presence interfered with the attendance of a poorer class who would give up their whole time to study. The prevailing spirit of the university was indolence. In 1558 Caius had spoken of the disappearance of "the poor, modest, diligent student who rose early, lived on scanty fare, and respectfully capped his seniors." Gone, too, were the dignified elders of former times, of sedate countenance and stately mien, punctilious in wearing academic dress, and punctual in attendance at the disputations in the schools. The undergraduates had discarded long gowns and caps, their garments were gaudy, they gambled and drank, and discipline was so much relaxed that those whose misconduct led to their expulsion from one college had no difficulty in obtaining admission to another.

The offices of the university became sinecures; for example, there seemed to be no objection to Ascham, the public orator of the university, living abroad, while Ridley retained his Mastership of Pembroke when Bishop, at first of Rochester, and afterwards of London. The doctor's degree was taken in scarcely any faculty, and as there were no examinations, and disputations had become neglected, such as were given could scarcely be regarded as evidence of learning or ability. If Cambridge had not sunk as low as certain German universities which Bucer condemns for giving degrees for money, yet there was much indolence among the resident Fellows, who lived like drone bees on the fat of the colleges.

In the new code of Edward VI, introduced in 1549, the textbooks of the professor of medicine were to be Hippocrates and Galen.

Foundation of Caius College.

In the reign of Mary (1553-1558) there was little in the state of the university to give satisfaction to any lover of learning, and the only fact which at this time can be regarded as conferring a real and permanent benefit upon the university was the foundation of the college that bears the name of Dr. Caius, who was private physician to the Queen, was nine times elected president of this College, and bore a professional reputation inferior to none of his contemporaries in this country.

Dr. Caius was a staunch Catholic, but he had travelled and seen much of men and things, so that he possessed an open and tolerant mind. He had studied anatomy under Vesalius at Padua, had visited other Italian universities, and had formed the acquaintance of the chief scholars of France and Germany. Being unmarried and wealthy and somewhat of a recluse, he retired to Cambridge, where he became a Fellow of Gonville Hall. In 1557 he obtained a licence from Philip and Mary to refound the college as co-founder with Edmund Gonville and Bishop Bateman, endowing it with the manor of Croxley and Snellshall and several other properties. When the college was reconstructed in 1572 it was to consist of a Master, thirteen Fellows, and twenty one scholars, the Master being a Bachelor or Doctor of one of the three faculties.

It is noteworthy as bearing upon the question of the state of medical education in Cambridge that the holders of medical Fellowships and those only were permitted to repair for the prosecution of their studies to the Continent, for, says the statute: "Theology and Civil Law may be studied just as well here as there," and it is fair to infer that medical science could not. These travelling Fellows were required to go to a "good school," preference being given to "Padua, Bologna, Monte Pulciano, and Paris."

Neglect of Learning.

On the accession of Elizabeth the fresh instructions to the Commission for the Reorganization and Reformation of the Universities followed closely those (1549) in the reign of Edward VI, but with the notable omission of the clause for the foundation of a Chair of Medicine and one of Civil Law. It is not necessary to recount the troubles and differences which occurred at Caius College owing to the personal unpopularity of Caius, who was disliked by the majority of the Fellows, and who retaliated by showing his contempt for their indifference to learning and their lax conduct, the manners of the students of this period leaving much to be desired.

We have seen that a generation before the study of Greek was pursued with much success at Cambridge, but it had become so neglected that eminent scions of the university, like Whitgift and Walter Haddon, were ignorant of it, and Giordano Bruno, who visited England and Oxford in 1582, complains that the Oxford undergraduate "drank too much beer," while his seniors were "pedantic and stupid"; but perhaps it is unfair to assume that these faults extended to the sister university. Companionable behaviour, the capacity to sit long at table after dinner and supper, were more helpful to a degree than reputation acquired in the schools, or any display of ability there evoked.

The attendance upon the lectures of the university professors fell off, no doubt in part in consequence of the development of the college system, undergraduates preferring to get such instruction as they desired in the classrooms of their college tutors; but if to the college system may be not unfairly attributed the decay of professorial teaching at Oxford and Cambridge, it may, on the other hand, be credited with having preserved these institutions from such stains on morals and manners as still mar the reputation of the chief German universities.

When Caius was in Italy he was a zealous disciple of Giovanni di Monte (1508-1552), who was the first modern to teach medicine at the bedside, which he did at the hospital of St. Francis. Unfortunately, Caius did nothing to transplant this method to his native country, and it was at least two centuries before clinical teaching was practised, even in a rudimentary fashion, in British hospitals.

Francis Glisson, Regius Professor of Physic at Cambridge.

The career of Francis Glisson, a former president of this College, illustrates to some extent the state of medical education at Cambridge, where he was Regius Professor of Physic from 1636 until his death in 1677. He entered Caius College in 1617, graduated B.A. in 1621, M.A. in 1624, and M.D. in 1634. He lectured at first on normal, morbid, and comparative anatomy, and in 1640 gave the Goulstonian lectures of this College. Up to this date—that is, four years after being appointed Regius professor—he lived in Cambridge, but in 1640 he took a house in Colchester, where he "soon obtained much practice" and where he continued to live until after the siege of that city, when he became much impoverished and moved to London. Here he took a house in New Street, in the parish of St. Bride's, and resided there up to his death in 1677. He was president of this College in 1667-8-9. In 1675 the university obliged him to appoint Dr. Brady as his deputy at Cambridge, but the fact that he was non-resident for over forty years of his incumbency of the professorship may not unfairly be taken to indicate the little interest felt in medical education at Cambridge.

As is well known, Glisson was an energetic student of his profession and published many valuable monographs, especially that on rickets and on the anatomy of the liver; by the latter his name has been preserved and is familiar to all medical students from "Glisson's capsule," applied to its external fibrous sheath. His portrait, painted at the age of 75, is in the possession of this College.

WEBSTER'S "EXAMINATION OF ACADEMIES."

One looks to Webster's book, the *Examination of Academies*,² for a criticism of the work of the university at or about Harvey's time, but it is disappointing. Webster was evidently a fanatical puritan who found fault with the universities because they professed to train men for the ministry, whereby they are said to fill them with vain knowledge. He expressed doubt whether the knowledge of Greek and Hebrew could in any way aid the right understanding of the Gospel, and thought that only the Spirit of Christ could convey this information. He praised such mystics as Jacob Boehme; he believed in the existence of a heavenly dialect, which was what John heard and God used in speaking to Adam; that animals probably communicated with one another by it.

He objected to the Aristotelian philosophy and preferred to it the teaching of the Rosicrucians, and that of our "learned countryman" Dr. Fludde. He condemned the medical profession for adhering to what he calls "ignorant, wicked and blind Pagans," for neglecting magic and cabalistic science and that "great book" the *Macrocosm* of Paracelsus. He quoted with approval the saying, "For the Lord hath created the physician, not the schools," and he condemned the neglect of that "laudable, excellent, and profitable science" of physiognomy, the neglect of the science of celestial signatures, and the study of natural dreams.

Coming to more reasonable criticism, he found fault with the uniformity of method followed in teaching by the slothful performance of the Acts, there being only four in the year, to these being conducted in Latin, which tended to obscurity and to the neglect of our mother tongue. He says that the "Romans used Latin and prohibited Greek" (?), while the Greeks wrote in their native language. He thinks too much importance is assigned to the opinions of the ancients, and that Lord Bacon has indicated a better method than that of the scholastic philosophy, that physics and chemistry should be taught by laboratories as well as libraries.

While there is much in this with which a modern would agree, the criticism on the whole is peevish and unreasonable, and suggests nothing that has any direct bearing upon the improvement of medical education.

Webster seems to have had small right to pose as the critic of the universities, for it is at least doubtful whether he was at any time a member of either of them. He speaks of himself as educated at Cambridge, but no trace of him can be found in the university registers according to the *Dictionary of National Biography*. He was ordained in 1632, was curate of Kildwick in Craven in 1634, and master of the grammar school at Clitheroe in 1643. In the civil war he seems to have taken the Parliamentary side, and

was surgeon and chaplain to a regiment in the Parliamentary army, becoming a Nonconformist and being "intruded" as vicar of Mitton in Yorkshire and also at All Hallows in Lombard Street. He acquired some fame as a preacher, but later on he fell into discredit, for his books were seized in 1657 and he gave up the ministry. Later in life he studied metallurgy and practised medicine. He died at Clitheroe in 1682.

"THE VINDICATION OF ACADEMIES."

Webster's book was answered by John Wilkins and Seth Ward in the *Vindication of Academies*.³ In this defence of the universities the authors complained that Webster, and even Hobbes, were ignorant of the present state of the universities and of the grounds of those arts and sciences which they pretended to improve. Surprise is expressed that the universities should be condemned as rigidly bound to Aristotle and accused of ignoring the modern advances in knowledge which have modified his teaching. On the contrary, all modern ideas were freely discussed—the anatomical and magnetical philosophy and the Copernican astronomy. It is said that both in the public lectures and private classes of the universities those things which they are accused of neglecting are taught and are well learnt. Particular exception is taken to the criticism which maintained that university teaching is not only useless but harmful to candidates for the ministry, for such academic knowledge "added to the gifts of grace must be only helpful and not injurious."

On the other hand, Webster's praise of the Rosicrucians, of Jacob Boehme and of judicial astrology show him to be a credulous fanatic. Further, Webster is accused of plagiarism, of stealing whole sheets of Gassendi's book, and of being wholly dependent upon those translations to which he had access for his knowledge of foreign writers. The accusation that the study of chemistry was neglected was denied, and with some reason it was pointed out that, the practice of medicine being an art which is based on observation and experience, new discoveries in anatomy do not always involve alterations in practice equal to that in theory, but have often confirmed and established practical rules.

Webster's objection to the use of the term "divines" as blasphemous is treated as ridiculous, but it is conceded that "theologian" is better, and the complaint of the use of the Scriptures in scholastic exercises is inconsistent with the desire expressed that Christian principles should be introduced into the schools of physical learning. Moderns may agree with the contention that students should be taught to use their hands in laboratory work, but there is force in the objection that the wishes of parents must be respected, and that in the sixteenth and seventeenth centuries it was not thought desirable to teach young gentlemen natural philosophy, chemistry, agriculture, or mechanics, but they should be trained to be rational and graceful speakers and fitted to move in polite society.

Webster's critic, John Wilkins, the Bishop of Chester, was one of the most learned and estimable men of that age. He adhered to the Parliamentary side in the civil war, and was Warden of Wadham College in 1648. He had the reputation of being a wise, beneficent, and tolerant head of the college, and he may be justly called the founder of the Royal Society. The weekly meetings of the London philosophers, when held in Oxford, took place in the Warden's lodgings. Although siding with the Commonwealth, he preserved the university from the ignorant commanders and soldiers who, unrestrained, would have demolished all places and persons that pretended to learning. He was afterwards appointed Master of Trinity College, Cambridge, where he was greatly honoured and loved, but at the Restoration he was deprived of this post, as it had been long promised to Henry Ferne. He was made Prebend of York and Dean of Ripon. He procured the incorporation of the Royal Society in 1662, becoming its first secretary. He lost his library and valuable MSS. in the great fire of London. He was made Bishop of Chester in 1668 and died in 1672. He is generally supposed to have written the preface to Seth Ward's *Vindiciæ Academicarum*.

"AN ARK FOR SUBMARINE NAVIGATION."

Bishop Wilkins was interested in many things, and Professor Joly, of Trinity College, Dublin, has recently

drawn attention⁴ to his little volume, entitled *Mathematical Magic*, in which one chapter is headed "Concerning the possibility of framing an ark for submarine navigation, the difficulties and conveniences of such a contrivance."

This invention seems to have been produced by a Dutchman named Cornelius Drebbel, who was born in Alkmaar in Holland in 1572, and came to England in 1604, where he secured the favour of James I, and was given lodgings in Eltham Palace. He left England at the invitation of the Emperor of Germany, but was involved in the misfortunes of the Thirty Years' War, when he was thrown into prison. Through the intermeditation of James I his release was procured, and he returned to England, where he remained until his death in 1634. He appears to have enjoyed the esteem of his contemporaries, especially of the Hon. Robert Boyle, who refers to him as a "deservedly famous mechanician and chymist."

The great interest to us of Drebbel's work is that he appears to have been much ahead of his contemporaries in appreciating the function of respiration. It is said that he built a ship in which a man could navigate under water from Westminster to Greenwich. In the boat "a person could see under the surface of the water, and without candlelight, as much as he needed to read in the Bible or any other book." This remarkable ship was in 1645 yet to be seen lying in the Thames or London river (C. van der Ooude). Boyle accepted the testimony of what he called "a few credible persons" that Drebbel could enable men to continue under water without suffocation or even inconvenience, for, as he says, it is "not the whole body of the air, but a certain quintessence or spirituous part of it that makes it fit for respiration, which, being spent, the remaining grosser body of the air is unable to cherish the vital frame." So that, besides the mechanical contrivance of his vessel, he had—

a chemical liquor which he accounted the chief secret of his submarine invention, for when from time to time he perceived that the finer and purer part of the air was consumed or over-clogged by the respirations and steams of those who went in his ship he would, by unstopping the vessel full of his liquor, speedily restore to the troubled air such a proportion of vital parts as would make it again for a good while fit for respiration, whether by dissipating or precipitating the grosser exhalations, or by some other intelligible way.

According to Boyle, Drebbel kept the nature of the liquor a close secret, and justified his own inquiry because the man and his invention were so extraordinary, all the more so as it was 150 years before the discovery of oxygen by Priestley and Lavoisier, and of the part played by it in respiration. It was not until 1681 that John Mayow published his conclusion that respiration and combustion are analogous phenomena. Drebbel must have discovered some means for removing from respired air its poisonous properties, as by drawing it through lime water to absorb the carbon dioxide, by which it would be possible to prolong the voyage, and the ventilation of the boat may have been assisted by pipes going to the surface, the air being drawn in by fans or pumps. It is certain that the bishop realized the difficulty presented by respiration in the problem of submarine navigation, and that he fully appreciated the work of Drebbel in overcoming this part of the problem.

While Harvey failed to grasp the function of respiration and set aside the suggestions that had been made by others under the crude form of the action of "spirits" on the blood, it is quite plain that these contemporaries of Harvey allowed their minds to run farther than his on the chemical side of these questions, and were closer than he to understanding the nature of the physiological questions involved. His failure in this respect was probably due to his ignorance of chemistry, which Aubrey says he was wont to undervalue, and speak against those who practised its doctrines.

BISHOP WARD.—OTHER CRITICISMS OF THE UNIVERSITIES.

Seth Ward, successively Bishop of Exeter and Salisbury, was a distinguished mathematician, mathematical lecturer at the University of Oxford, and afterwards Savilian professor of astronomy in 1649. He entered as a Fellow Commoner at Wadham when John Wilkins was warden, and when the fame of the college attracted many men of eminence. These gatherings probably constituted the nucleus of the Royal Society. After the Restoration he was made successively Prebend, Dean and Bishop of Exeter. He was subsequently translated to Salisbury,

and became Chancellor of the Order of the Garter. His controversies with Hobbes and Webster caused him some trouble. He is the reputed author of the *Vindiciæ Academicarum*, in which he replied to the criticisms of the universities which Webster and Hobbes had published in the *Academicarum Examen*.

Hobbes, the author of *The Leviathan* (1588-1679), was a somewhat bitter critic of the universities in his day, particularly on the ground of their adherence to the Aristotelian philosophy and physics. He says: "The philosophy schools through all the universities of Christendom grounded upon certain texts of Aristotle," and these institutions were merely useful as a handmaid to the Roman religion; they rendered no knowledge of the subordinate and secondary causes of natural events or "physiques," but merely empty words. Thus they said that bodies sank because they are heavy or because they desire to be at rest. He also criticized their teaching of the civil law, but although there was doubtless much with which to find fault, he says nothing about the art of medicine or the way in which it was taught.

Dr. C. A. Mercier⁵ is of opinion that Paracelsus and van Helmont had much to do with preparing the ground for the reception of Harvey's new doctrine. He thinks that by their bold challenge to the Aristotelian doctrines they rendered it possible for Harvey to state his novel opinions without being regarded as uttering blasphemy, but he is almost as severe a critic of Oxford and Cambridge as was Hobbes two hundred years earlier. He quotes a statement of Averroes that Aristotle is "the perfection of truth, that his understanding attained the utmost limit of human ability," and that "it may truly be said of him that he was created and given to the world by Divine Providence, in order that we might see in him how much it is possible for a man to know." This tribute may seem exaggerated to the non-academic mind, but "it would not be considered at all exaggerated in the University of Oxford even to-day." He gives no facts whatever in support of this charge. However, there may be something in what he says, for had not Paracelsus and van Helmont shown that Aristotle could be contradicted without calling down fire from heaven, Vesalius might not have had the courage to publish his discovery of the non-porosity of the cardiac septum.

TEACHING OF MEDICINE AT CAMBRIDGE IN HARVEY'S TIME.

It is not easy to trace any evidence of the teaching of medicine at Cambridge in the time of Harvey. In vol. iii of Venn's *Biographical History of Gonville and Caius College* (p. 253) we find the following:

It will be observed that no reference has been made in the above sketch to any such officer as a medical lecturer. The fact is that though the College had for centuries enjoyed a medical reputation, no trace of any systematic instruction in the subject can be discovered until very recent times. Indeed, the earliest lecturer recorded by tradition is the late Sir George Paget, who is known to have held the office from about 1848 until he ceased to be a Fellow in 1852. Since that date such lecturers have been regularly appointed. The increased scope of the work, owing to the great addition to the number of students, was recognized in 1851, when the title was changed from Medical Lecturer to Lecturer in Natural Sciences and Director of Medical Studies. That some instruction, however, in the shape of what we should now call anatomical demonstration was occasionally given in the College can be proved by one or two interesting facts. In the first place, in the register of the parish of St. Michael—the College lies in the parish—there is an entry of burial under the date April 6th, 1601, of "Mr. Hutton, the anatomyr of Key's College."

Venn took it for granted at first that this gentleman's connexion with anatomy was of the active kind, and that we had here evidence of a very early demonstrator in the college. But it now seems certain that he played the part of the subject, for it is recorded that Dr. Grimston, "one of our Fellows," made a dissection in the college just four days before. That similar instruction was carried on twenty-five years later seems plain from the statement of Dr. Joseph Mede, that he attended anatomy lectures in "our College." In the register of Great St. Mary's, the parish in which the schools, now absorbed into the public library, were situated, several such entries are found. The earliest of these is in 1566, when it is recorded that "John Figgen mad anatomy at the scholes and buried here, the 12th March." This was during the residence of Dr. Caius, seven years before his death.

Professor A. Macalister informed Dr. Venn that this is the earliest contemporary record known to him of the actual performance of human anatomy in England. Again, in 1628, there is an entry that "John Smith, a prisoner at the castle that was anatomised, was buried." In a note, Dr. Venn says that it perhaps accounts for the prefix "Mr." to Hutton's name, a title at that time confined by university usage to Masters of Arts and Fellow Commoners, in the direction of Dr. Caius that the burial of such anatomized bodies should be "orderly and reverential."

In the same volume (p. 47) we find the following:

On the same day (Patent Roll, August 1st, 1564) is added the Royal License, for the purchase of the houses from Trinity. A new and very important concession was included in this license. It was a formal grant from the Queen (Elizabeth) of bodies for dissection to the effect that "they and their successors shall have for ever, at their free discretion and will, without the contradiction of anyone, two human bodies for anatomy, condemned by law for theft or homicide and dying in the town castle or county of Cambridge. And that they may freely dissect them at their will, with the reverence due to the human body, for the increase of medical knowledge: and this without any payment." Dr. Caius gave careful directions in his statutes concerning these dissections, desiring that "every year during the winter there shall be spent by the students of our College, on anatomy and on the worthy burial of the dissected bodies at St. Michael's 26/8. The president and everyone residing in College to attend the burial of the remains with as much respect and ceremony as if it were the body of some more dignified person; and this on account of the advantage they have thus received. And the Master shall see that the students of medicine do not treat the body with any lack of respect or humanity." It is to be feared that very inadequate use was made of this privilege.

In his *Advancement of Learning* Bacon mentions that the study of medicine was based upon the use of dead bodies for dissection.

It is further evidence that dissection was practised in Cambridge in the seventeenth century that Sir Charles Scarborough (1616-94), who was a Fellow of Caius College, published a manual on dissection (*Syllabus Musculorum*), but there appears to have been no dissecting room, public or private, until after the passing of the Anatomy Act, 1832. Science and its votaries, indeed, found no permanent home at Cambridge in the time of Harvey. Gilbert of Colchester, who, as Bacon says, had made a philosophy out of a loadstone, had been long removed to London, where as royal physician he enjoyed favour and good fame, and died in 1603. Physiology as a subject did not exist, and the knowledge of the functions of the organs, apart from their structure, was elementary and very often fundamentally erroneous. In spite of Bacon's commendation, morbid anatomy was entirely neglected, perhaps because, as he pointed out, this study was much more difficult than that of normal anatomy, the latter being presumably uniform in all healthy subjects, while the former presented endless variety. Its difficulty undoubtedly hindered any advancement, for it is not until the second half of the nineteenth century, when fairly complete *post-mortem* examinations were made on the bodies of all persons dying in hospitals, that the subject became familiar, and morbid appearances grew to be generally known to hospital physicians, and were expected to a less extent from students.

IMPULSE GIVEN BY HARVEY TO BRITISH PHYSIOLOGY.

There can be no doubt that in the sixteenth and seventeenth centuries those Cambridge men who desired to study scientific medicine could not do so at home, and resorted to the Italian universities to study under such great masters as Vesalius, Fallopius, and Eustachius, whose success was rather in descriptive anatomy than in physiology. Harvey's work was of great importance because, although he added no new facts, he placed a new interpretation on what had been more or less common knowledge for 2,000 years, and stimulated an advance in medicine which has continued up to the present time. This advance was mainly due to his employment of vivisection, by which method he laid the foundations of physiology and thereby of the progress of medicine. Physiology has been rightly called the Institutes of Medicine, which must march hand in hand with pathology and be its guide. Its progress depends upon the advance of many sciences, especially of chemistry, in that department which we call organic or physiological. This was a new science forty

years ago, and has been built up within the lives of many of us. It has opened out a wide prospect and gives promise of revolutionizing medical study.

The impulse that the work of Harvey gave to British physiology is shown by naming those who followed him in the next one hundred years.

Thomas Wharton (1614-73), physician to St. Thomas's Hospital, studied at Cambridge and Oxford, discoverer of the sub-maxillary gland, and author of *Adenographia* (1656).

George Joyliffe (1627-58), M.D.Cantab., F.R.C.P., discoverer of the lymph ducts.

Francis Glisson (1597-1677), M.D.Cantab., Fellow and President of this College, author of famous monographs on rickets and the anatomy of the liver.

Thomas Willis (1621-95), M.D.Oxon., F.R.S., F.R.C.P., recognized saccharine diabetes and described the anatomy of the brain (the circle of Willis).

Richard Lower (1631-91), M.D.Oxon., F.R.S., F.R.C.P., performed transfusion.

Edward Tyson (1650-1708) and Samuel Collins (1618-1710) were comparative anatomists.

Clopton Havers described the Haversian canals.

William Cowper or Cooper (1666-1755) described "Cowper's" glands.

ADVANCE OF MEDICINE IN SECOND HALF OF NINETEENTH CENTURY.

But it cannot be claimed that at Cambridge or elsewhere there was any real progress in medical education. Here and there men of genius made discoveries, but they were not aided by any organization either inside or outside the university or medical school. Men like the Hunters did their work at their own expense, and for many years to come even the teaching of anatomy owed most to what was done in private schools.

The best that can be said for British medical education is that it was based upon some genuine knowledge of practical anatomy and bedside acquaintance with diseases. But it was not until the second half of the nineteenth century that a true spirit of reform entered into the schools. In no place was this more manifest than at Cambridge. Although it is still necessary, and probably always will be, for the Cambridge student to seek clinical experience elsewhere, he may find at Cambridge all that he desires in laboratory opportunities, and, within due limitations, for clinical research.

If Cambridge has proved itself worthy of its association with the illustrious Harvey, this is equally true of the great hospital of St. Bartholomew's, with which perhaps his professional connexion is more generally recognized. Harvey left Cambridge apparently as soon as he had completed his arts curriculum, taking no part of his medical education there, and, although he returned there for his degree, he owes to Italy the instruction that opened the way for his great discoveries.

HARVEY AS PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

Of his labours as a physician at St. Bartholomew's we know little, and what records remain do not impress us very favourably with the work done in those days by those who held such appointments as that of Harvey. When he was originally appointed he was only obliged to attend once a week, and he was never formally required to visit the wards. The number of patients seen in the hospital must have been very small, for as late as 1749 the numbers are given as—in-patients, male 16, female 15; out-patients, male 50, female 50 each week; and there is no reason to believe that a hundred years earlier they were more numerous.

Apparently the patients were obliged to come to the doctor and not the doctor to the patients, as one of the rules says:

It is the duty of the matrons and sisters to complain to the doctor if any poor lurk in the house and do not come to him at his sittings or take the medicine he prescribes, but cast it away and abuse it.

It is difficult for us to understand the position of such a man as Harvey holding a post which, to us, seems scarcely likely to afford him any return in the way of useful experience. The salary was inconsiderable, some £20 a year with an allowance for fuel and "livery," but it is possible that the appointment indirectly led to a certain amount of practice, for undoubtedly he made money by his profession, although Willis suggests that his brother Eliab employed the "small capital" accumulated

by him during his active years of practice and before the breaking out of the civil war to such good account that he actually died a rich man. The period during which he may have earned a considerable professional income must have been from about 1607 to 1630.

HARVEY'S LATER YEARS: HIS GIFT TO THE COLLEGE.

After the latter date, when he went abroad with the Duke of Lenox, it is doubtful whether he ever had much opportunity for practice. In 1633 he went with Charles to Scotland, whence he followed him to Oxford (1642), and in 1646, on returning to London, he resigned all his appointments, and as his wife was dead he took up his residence with his brothers Eliab and Daniel. It was then that Harvey felt himself fully justified in making over his paternal estate, then worth £56 per annum, to this College as a free gift during his life and as a provision for the objects of which this annual oration forms part.

He died at the advanced age of 80 on June 3rd, 1657, and I cannot do better than repeat the words of Willis:

So lived, so died one of the great men whom God in virtue of His eternal laws bids to appear on earth from time to time, to enlighten and to ennoble mankind.

THE CURE OF INGUINAL HERNIA.

BY

LIEUT.-COLONEL ALFRED J. HULL, F.R.C.S.,

ROYAL ARMY MEDICAL CORPS.

The high percentage of men who suffer from inguinal hernia has made the problem of their treatment a serious one during the present war. Trusses appear to be most unsatisfactory when used by soldiers. In my personal experience I have rarely seen a truss controlling a hernia. The truss appears to be worn for choice with the hernia unreduced. It may be stated that we regard an inguinal hernia as a congenital deformity due to the presence of an abnormal process of peritoneum. This defect is combined with a lesser acquired defect—namely, an abnormally long process of omentum, or more rarely mesentery. The treatment indicated appears to be abolition of the abnormal process of peritoneum and removal of the redundant omentum. The choice of an operation which will cure the hernia and render a man fit for service in the shortest possible time becomes desirable. Having had charge of a special department for the cure of hernia, dealing with cases at the rate of about 500 a year, the need for a simple operation giving adequate relief and followed by a rapid convalescence has been impressed upon me.

It occurred to me that much of the trouble following the operation for radical cure of hernia, and many of the recurrences, were due to the well-intentioned but ill-advised efforts of the surgeon to effect repair. Bearing in mind that the success of an operation lies in the simplicity thereof, I evolved the procedure described below. The majority of herniae occurring in men of military age are amenable to cure by a small operation. The operation described below has been performed as a routine method in all cases. The advantages of this operation as a treatment in the hernia of children will be apparent. The principles borne in mind are to remove the sac at the highest possible level with the minimum disturbance of tissue. The cutting and interference with tissues has been reduced to such a degree that very rapid convalescence follows, and the reaction associated with hernia operation is obviated. The advantages of an operation which reduces the cutting of tissues down to an inch incision in the skin and superficial fascia, and a small incision in the spermatic fascia, will be apparent. No dissection of tissues is undertaken; just as Matas in his operation for aneurysm avoided injury and disturbance of surrounding structures by attacking an aneurysm from within the sac, we avoid dissecting, cutting, or injuring the delicate or important structures which surround a hernial sac by attacking the hernia from within the sac.

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

FIG. 6.

FIG. 7.

FIG. 1.—An incision about an inch in length has been made, half an inch above Poupart's ligament, over the femoral point. The fibres of the external oblique aponeurosis have been split for a short distance.

FIG. 2.—The edges of the aperture in the external oblique have been retracted by the forceps, A, exposing the coverings of the spermatic cord. The forceps, B, have been placed upon the aperture in the cremaster, which has been made by inserting the closed points of Mayo's scissors and opening the blades. The spermatic fascia is exposed in the depth of the wound.

FIG. 3.—After incising the spermatic fascia the sac has been found and drawn out of the wound. The forceps, A, remain on the external oblique during the whole operation.

FIG. 4.—The sac has been opened and its aperture retracted by forceps, after having been enlarged by snipping the edges between the forceps. Two apertures are displayed divided by a process of peritoneum. The aperture A leads into the abdomen.

FIG. 5.—Forceps have been placed on the crista; a layer of peritoneum has been picked up on its mesial side and this layer is being cut with scissors. By lifting the forceps 1, 2, 3 the clean neck of the sac will be held ready for ligature, isolated from the remainder of the sac B by this incision.

FIG. 6.—The forceps 1, 2, 3 have been raised. The neck of the sac is isolated from the remainder, which has shrunk within the coverings of the cord.

FIG. 7.—Suture of the neck of the sac.

Without entering on the debatable ground of statistics, I am prepared to state definitely that fewer recurrences take place after this operation than after any other method of which I have experience. In hernia, as in other operations, the results depend largely on the selection of cases, and probably any experienced surgeon could operate upon a number of hernia cases by any method with only a small percentage of failures if allowed to choose his cases.

The Operation.

We perform this operation under local anaesthesia as a routine measure. Local anaesthesia possesses great advantages over general anaesthesia for hernia operations. A half per cent. solution of novocain, to which a small quantity of adrenalin is added, is used. The needle of the analgesia syringe is entered at a point midway between the anterior superior iliac spine and the spine of the pubes half an inch above Poupart's ligament. The whole anaesthesia is conducted through this puncture without withdrawing the needle. An incision from half an inch to an inch in length is made over the needle puncture and carried down to the aponeurosis of the external oblique. The fibres of the external oblique are split for a distance of half an inch. The opening in the external oblique should lie directly over the spermatic cord. The cremasteric and spermatic fascial coverings of the cord are drawn through the aperture of the external oblique. The cremasteric fibres are separated and the spermatic fascia incised; the sac is then found lying inside these coverings. Two pairs of fine haemostatic forceps (Halstead's mosquito forceps) are placed upon the edge of the sac, and an incision, half an inch in extent, made between them by a snip of a pair of scissors. The two layers of the sac forming the lips of the aperture are now clipped with haemostatic forceps. The aperture can now be held open by four pairs of forceps, and four incisions are made, one between each pair of forceps, enlarging the aperture sufficiently to display the interior. If omentum lies in the sac it is drawn out, ligatured, and cut off. The interior of the sac presents for examination two apertures, one the internal ring passing into the abdomen, the other passing down the inguinal canal. These apertures are separated from one another by a process of peritoneum, the "crista," and in a well-marked case the apertures resemble the muzzle of a double-barrel shotgun.

The process of peritoneum called the crista corresponds to the internal margin of the internal ring. Forceps are clipped on to the crista in one or two places. It is now necessary to separate the important tube of peritoneum leading into the abdomen (the neck of the sac) from the unimportant tube leading down the inguinal canal. This is done by cutting along the crista to the mesial side of the forceps, and dividing one layer of peritoneum with scissors. As the result of this incision the neck of the sac now lies clear, held by the forceps on the crista on its mesial side, and the forceps on the outer side of the sac. The neck of the sac has in this way been completely exposed and freed without dissection. A gauze swab is gently passed down the outer and inner side of the sac. A gentle pull is made upon the neck of the sac whilst it is ligatured as high up as possible. It will be remembered that the crista corresponds to the internal ring, and by separating the crista forming the neck of the sac in the manner described above, and pulling upon the sac, it has become possible to ligature the peritoneum, forming the neck of the sac, about two inches above the internal ring. It is unnecessary and undesirable to perform any displacing manoeuvre to the neck of the sac. When the sac is cut off distal to the ligature, the elasticity of the peritoneum will displace the ligatured sac well behind the rectus muscle. In 90 per cent. of cases this is all that it is necessary to do, and the skin incision is sutured with silkworm gut passing down to, and taking up the edge of, the external oblique. In cases in which a large internal ring or very thin peritoneum renders a recurrence more possible, the conjoined tendon is drawn over the cord and sutured to Poupart's ligament without enlarging the wound. In exceptional cases it may be considered desirable for similar reasons to convert the operation into a typical Bassini operation. This can be done with ease by enlarging the split in the external oblique for another inch or more, lifting the cord, and suturing the compound tendon of the internal oblique and

transversalis beneath it to Poupart's ligament. Experience has shown that when a recurrence takes place it is usually an immediate recurrence. The recurrence occurring immediately the patient gets up is due to faulty ligature of the neck of the sac. The elastic peritoneum, released after ligature of the aperture, is very liable to slip the ligature. This cannot occur if the aperture formed by the neck of the sac is sewn in addition to simply tying the ligature.

The majority of herniae occurring in men of military age are small bubonocoeles or congenital herniae containing omentum.

I attach considerable importance to the removal of the prolapsed omentum, which is always of abnormal length, with a view to preventing recurrence.

Several sequelae follow hernia operations which are of more significance than recurrence. I refer to such conditions as hydrocele, retraction of testicle, thickening of the spermatic cord, painful scars, neuralgia, and enlargement of the testicle. These unpleasant and almost incurable results are due to damage to the spermatic cord, the delicate structures of which are adversely affected by much less disturbance than is usually supposed. In the operation described the only content of the cord which is either seen or touched is the sac.

I have found this operation of particular value when dealing with cases of recurrent hernia. The new operation is performed above the matted scar tissue of the old operation and completed by Bassini's method almost with as much ease as a primary operation.

MODERN ARTIFICIAL LIMBS AND THEIR INFLUENCE UPON METHODS OF AMPUTATION.*

GENERAL CONSIDERATIONS.

BY

E. MUIRHEAD LITTLE, F.R.C.S.,

CONSULTING SURGEON TO QUEEN MARY'S CONVALESCENT HOSPITAL,
HOSPITALS, ROEHAMPTON; SENIOR SURGEON TO THE ROYAL
NATIONAL ORTHOPAEDIC HOSPITAL, ETC.

It may seem at first sight that the title of this paper implies a putting of the cart before the horse; that the artificial limb should be influenced by the amputation which calls it into being, and that the converse should not occur. But unfortunately we have to cut our coat according to our cloth, and the cloth in this case is limited by the mechanical possibilities at our disposal.

Artificial limbs have been used for many centuries, for a Roman artificial leg has been unearthed at Pompeii. The artificial hand of Götz von Berlichingen, made in 1509, is still in existence and in working order and has lately been described in detail in the *Zeitschrift des Vereines Deutscher Ingenieure*, December, 1916. With this hand it is said that Götz was able to strike a harder sword stroke than with his former natural hand. (*Credat Judaeus.*)

In order to produce good results the surgeon and the limb-maker must have some knowledge of each other's limitations.

On the one hand, it is undesirable for the surgeon to design and carry out an amputation, however successful surgically, if the resulting stump is one to which an artificial limb cannot conveniently be attached. On the other hand, it would be useless for a limb-maker to devise a limb, however perfect in theory, if it could not be borne by the patient's stump.

In this country of late years the questions connected with amputations have been of diminishing importance, thanks to Lister and the Employer's Liability Acts, etc. So that, as I learn from my friend Mr. Edred M. Corner, in 1913—the year before the war—out of 5,483 major operations at St. Thomas's Hospital there were only 34 amputations; a proportion of 1 in 161. The Royal Surgical Aid Society, which supplies appliances not only in London but also in the provinces, in 1913 supplied 529 artificial and peg legs and arms out of 41,483 appliances supplied in that year.

* Papers read at the meeting of the Medical Society of London, October 22nd, 1917.

In the United States of America it would appear that amputation was a much commoner operation, not because of any lack of conservative surgery, but because accidents were relatively and absolutely much commoner in that country. The large number of cases of amputation in survivors of the War of Secession gave an impetus to the design and manufacture of artificial limbs, which was sustained by the steady demand caused by accidents in civil life, and a large number of limb-makers get their living in the United States.

The Best Forms of Stumps.

The conditions of the problem differ in the upper and lower extremities.

In the lower extremity the functions of the lost part are crude compared with the delicate and nicely adjusted and co-ordinated movements of the upper extremity. Its chief duties are to support the weight of the body at rest and in motion and to act as the propellant force in the process of locomotion. End pressure and leverage are the strains to which it is most exposed.

The upper extremity is mostly employed in prehension and traction—functions to which the foot of boot-wearing man is a stranger, and end pressure, therefore, is not one of the most important strains to which it is exposed, while leverage is all-important. As the movements of the hand and fingers are highly co-ordinated and often very delicate, it follows that the problem here is a very difficult one. In fact the best artificial arm and hand is but a poor substitute for the living member, while the artificial leg can be made to do nearly everything that is required of its living predecessor—to do it, that is to say, more or less well, though not so well as the latter.

In both the upper and lower extremities provision has to be made to maintain the appliance in place when in action, and also when at rest, against the action of gravity.

Weight is borne in two ways, often or generally combined—

(a) By direct pressure of a part of the body downwards, such as the end of the stump, or of a convenient bony process such as the tuberosity of the ischium, or

(b) By oblique pressure, when the artificial socket forms a more or less conical cavity into which a conical portion of the body fits.

Leverage is exerted by the lateral surface of the stump pressing against the side of the surrounding socket.

It is necessary to state so much in order to understand what a stump should be, but I do not propose to go into the question of mechanics, because my colleague, Major Elmslie, may be trusted adequately to deal with that side of the question.

An ideal amputation stump would be as long as possible, it would be covered by sound movable soft parts, and the scar would be placed in a position where it would not be exposed to pressure, and it also would not be adherent to the bone. It would have enough muscles attached to it to move it with adequate force, and no inflamed or hypersensitive nerve ends would be palpable in it.

The end or ends of the bone or bones would be rounded so as not to hurt the soft parts under them, and the blood supply would be free and the skin well nourished.

Objections to Exarticulation.

At first sight it would appear that this ideal is most nearly approached by an exarticulation, which preserves the full length of the limb segment and does not involve any section of bone, with its possibilities of infection and necrosis. Further consideration and experience of modern artificial limbs lead to the conclusion that, except in the cases of the hip and shoulder, exarticulations are to be avoided, and that amputation through the limb segment above the joint is to be preferred.

The following weighty objections to amputations through joints have been made and, as I think, may be accepted as valid:

1. The articular enlargement, which is a prominent feature of all long bones, makes the resulting stump bulbous in form; a form which becomes more marked as atrophy of muscles goes on, leaving the dimensions of the bone unaltered. Such a bulbous stump, larger in girth at its lower extremity than at its middle, cannot be

closely fitted with a rigid socket, such as forms the best support. Also the artificial limb must be wider than the natural one by the thickness of the walls of the socket.

2. The artificial joint must either be fitted below its proper level or else it must be placed on the sides of the bone end and the limb must be still wider than its fellow and consequently unsightly.

3. To cover the articular enlargement extensive flaps are needed, and these must sometimes be of thin skin. Such flaps are often deficient in vitality and likely to slough.

Weight-bearing Stumps.

Before the war osteoplastic operations designed to produce stumps capable of bearing weight on their ends were getting more and more into favour. In this category must be included the Stokes-Gritti operation above the femoral condyles. The stumps so produced are excellent, but conditions favourable for their production are so rare in this war that we may put aside the consideration of these operations at present. I am sure that I am within the mark in saying that among some 5,000 amputations which have passed through my hands at Roehampton there have not been a dozen cases of the Stokes-Gritti.

In the lower extremity a stump capable of bearing some at least of the body weight on its end should be aimed at. Every pound of pressure here means less pressure on other parts, which in some cases do not bear it well.

There appears to be a diversity of experience and consequent opinion on this point. At the extraordinary meeting of the German Orthopaedic Society in February, 1916 (as reported in the *Zeitschrift für Orthopädische Chirurgie*, Band xxxvi, Heft 23), both Gocht and Dollinger stated as their experience that in this war hardly any stumps were fit to bear weight on their ends; but Ferdinand Seidler, of Vienna, at the same meeting, said that out of 500 stumps, 297, or nearly three-fifths, were fit to bear weight. Perhaps the discrepancy may be explained by supposing that Gocht and Dollinger meant "nearly all the weight," and Seidler meant "some of the weight" only.

I should premise that, in speaking of upper, middle, and lower thirds, reference is made to measurements of the bone and not of the length of stump available for application of a bucket. Limb-makers, however, generally refer to measurements taken from the fold of the axilla or elbow, the pubes, or the ham, which are obviously very different. It is the custom at Roehampton to measure the remaining bone as accurately as possible with a simple form of callipers, and not to trust to the eye to estimate length in thirds. The average length of a long bone being known, a simple division sum gives the correct result.

My own experience tallies with Seidler's. Thus—

An analysis of the records of 549 cases of amputation of the lower extremity seen recently at Roehampton shows that in 275 of these—almost exactly half—it was found advisable to fit an end-bearing pad. As might be expected, the proportion varied widely in the different regions. In the upper third of the thigh only 9 per cent. were thus fitted, in the middle third 32 per cent., in the lower third 77 per cent.

Cases fitted with End-bearing Pad.

Upper third of thigh	...	2 out of 22	=	9 per cent.
Middle third of thigh	...	75 " 235	=	32 "
Lower third of thigh	...	63 " 81	=	77 "
Through the knee-joint	...	5 " 6	=	83 "
Upper third of leg	...	42 " 74	=	56 "
Middle third of leg	...	64 " 98	=	65 "
Lower third of leg	...	6 " 14	=	43 "
Syme's amputation	...	12 " 14	=	86 "

Three Stokes-Gritti and two Pirogoff's amputations were all capable of bearing weight on the end of the stump.

The number of cases in some of these categories is too small for the formation of very definite conclusions, but the main facts which come out are that the stumps in the lower third of the thigh are much more sound than those in the upper and middle thirds, which latter region is the seat of nearly half of the total number (43 per cent.).

The surgeon who has to deal with many of these end results cannot fail to be struck by the prevalence of wide adherent scars in the upper two-thirds of the thigh. Some of these, not many, are unmodified guillotine operations; the majority are not, and many are, the results of later operations in which attempts have been made in vain to produce a stump covered by sound skin. Some of these

unfortunate persons have suffered as many as seven amputations on the same limb.

In the upper extremity the question of end pressure does not arise, and here the condition of the lower part of the anterior and external surfaces of the stump is of most importance, because these surfaces have to take much of the pressure of the leverage action on the bucket. Many arm stumps with large adherent guillotine scars covering the end of the bone have been found to be quite satisfactory in practice.

The presence of osteophytes is rarely any hindrance. These are seldom large, except in the thigh, and then they are usually situated about the femoral insertions of the adductor muscles, which are not exposed to much pressure.

DIFFERENT SITES OF AMPUTATIONS.

The Upper Extremity.

A forequarter amputation gives no choice of flaps. The resulting scars will generally bear a properly moulded shoulder-cap and an artificial arm with some movements.

In exarticulation at the shoulder the lines of scar should avoid the clavicle and the prominent bony ridges of the acromion, etc., for on these the shoulder-cap must press.

Amputations in the upper third of the arm offer very little hold for the socket of an artificial limb. Owing to the arrangement of the muscular attachments around the joint the upper three inches of humerus, or even more, are unavailable, and as in the arm of average length the upper third is only a little over four inches long, very little is available even in an amputation at the junction of the upper and middle thirds. A good deal can be gained by removing wholly or in part the folds of the axilla, that is, the pectoralis major and the teres major. This has been done with good result and seems to be an operation worth doing in suitable cases. The latissimus dorsi has not been interfered with so far as I know. It is less in the way than the other two muscles.

A gain of one inch of stump here is of the very greatest value, and as large adherent scars covering the end of the bone are comparatively unobjectionable in the arm, the surgeon in amputating above the middle of the shaft of the humerus should save as much bone as possible, even though there may not be skin enough to cover it completely.

The drag upon the adherent scar, which gives trouble in the lower extremity, is seldom complained of in the upper, owing to the absence of much upward thrust.

The objections to amputations through joints in general apply to the elbow in particular force, owing to the shape of the bones. If it is impossible to get a forearm stump extending at least an inch and a half below the insertion of the tendon of the biceps, amputation above the condyles of the humerus is to be preferred.

Similar considerations are of weight here to those mentioned in discussing the shoulder region. The action of the biceps tendon, which tends to throw off the bucket when it contracts in flexion, is one of the chief difficulties in these short forearm stumps. Unfortunately, this tendon cannot be spared, and its removal is out of the question. The remains of the bellies of the flexor muscles, however, are of no use, and have been removed in some cases with more or less advantage, enabling a better grip on the stump to be obtained.

The middle third of the forearm gives good stumps, but the lower third is not a favourable site. Many stumps here are cold and cyanotic and the skin tightly stretched and adherent. Moreover, the ends of the bones are often tightly soldered together by fibrous tissue or even bone, and the movements of pronation and supination are lost.

It is true that the most directly acting pronator, the quadratus, is sacrificed if the lower third is removed, but experience leads to the conclusion that good voluntary movement is possible without it, if the ends of the radius and ulna are free. It takes some time and practice, however, to enable the patient to carry out these movements, even when fitted with a suitable arm. The tendency is to use the shoulder-joint instead of the radio-ulnar.

Below the wrist, if the carpus and base of the metacarpus can be saved, it is worth while, provided movement is preserved. The short stump thus formed can be used to actuate a movable thumb with considerable force by means of a simple appliance. It is a commonplace of

surgery that any part of a finger or thumb is worth saving. If one active finger or a thumb is left it is easy to fit a stump to which it can be opposed and thus to give the picking-up action and the power of holding a pen.

The Lower Extremity.

I do not hesitate to affirm emphatically that in the lower extremity exarticulation or amputation between the trochanters is better than amputation in the upper third of the thigh. I refer to the upper third anatomically speaking, which in the average limb includes a little more than six inches of femur, which gives only three or four inches of stump below the pubes. Such a short stump is unable to move the lever formed by the thigh bucket with sufficient force, no matter how light the limb may be.

Such improvements have been made in fitting what is rather inaptly called a "tilting table," that patients who have tried both the ordinary thigh bucket and this appliance usually declare that the latter is much the best. Certainly they walk better in it. This form of prosthesis (shown and described to you by Major Elmslie) forms to my mind one of the greatest improvements in artificial limb-making during the war. Although known and used for some years before, it has been developed and perfected in details during the last two or three years.

In the middle and lower thirds of the thigh the general considerations apply, which I have already outlined. The middle third is the site of nearly half the amputations of the lower extremity treated recently at Roehampton. The exact figure is 42.8 per cent. No other region approaches this in frequency, the next being the lower third of the thigh and the middle third of the leg, each with 11.6 per cent. only.

In this region the objects aimed at should be a non-adherent scar behind the bone, and a good disposition of the muscular masses on the inner side. If the great adductor muscles are allowed to retract too much a too conical stump results, and the bunch of soft parts at the top of the thigh just below the pubes forms a serious obstacle to the fitting of a socket. The tendons and fasciae should therefore be sutured if possible over, but at least near to the end of the bone.

In this connexion it may be worth while to recall that the femur on a thigh stump is eccentrically placed. It is almost subcutaneous along the outer side of the thigh and most of the lateral pressure of the artificial limb is borne on this outer surface. This position is very obvious on x-ray plates. Therefore in making incisions preliminary to or during amputation this surface should be spared if possible.

Although in injuries about the hip in civil life adduction is the common resulting deformity, after amputations of the thigh adduction is a frequent result, and adduction is hardly ever seen.

One of the greatest troubles of the orthopaedic surgeon and the limb-maker is the prevalence of flexion contraction of the hip in cases of thigh amputation. In treating such serious injuries it is natural that the primary consideration should be the early and complete healing of the wound. To secure this and for the comfort of the patient the stump is often propped up upon a pillow, thus favouring shortening of the flexors of the hip. This contraction, unless very severe, is masked by a compensatory lordosis and often unsuspected by those concerned, but when the patient is examined with the sound thigh well flexed upon the abdomen, the true state of affairs is revealed.

Practically every case of amputation of the thigh which is admitted to Queen Mary's Hospitals at Roehampton is found to have some flexion contraction, or diminution of the normal range of hyper-extension, and has to undergo a course of massage and passive motion, or the operation of tenotomy and fasciotomy, before a leg can be satisfactorily fitted. The structures most concerned are the tensor fasciae femoris, the long adductors, the ilio-psoas, and sometimes even the capsule of the hip-joint.

It is much to be wished that, in every case in which the general conditions are favourable, the stump should be fully extended while the opposite thigh is fully flexed upon the abdomen at least once daily during treatment of amputations in this region.

The lower third of the thigh, just above the condyles, offers the best thigh stump for fitting with an artificial limb. If a long anterior flap is made, even though there

may be an adherent scar behind the bone, a good end-bearing stump often results. If the patella can be securely fixed to the end of the bone so much the better.

The general objections to exarticulations apply to the knee-joint. Not many such stumps are satisfactory.

In the leg below the knee the most favourable site is the lower part of the middle third. The old seat of election about four inches below the joint was intended for kneeling legs. Nowadays kneeling legs are avoided and only used when a stump below the knee is too short to work a socket. With skilled fitting, however, even very short stumps are useful. A good gait has been obtained with as little as two and a half inches of tibia, but this was an exceptional case. Rarely is a good result obtained with less than three inches, and then generally the stump should be capable of end-bearing. Much depends on the bulk of the soft parts. When these are voluminous, the difficulty is increased.

These short leg stumps give a better gait than is got with a kneeling leg, and the artificial limb is less unsightly. Amputation in the lower third of the leg seldom gives a satisfactory stump. The bone surface at the end is too small for good weight-bearing, and the skin is often badly nourished, cold and cyanotic.

No one can deal with many below-knee stumps without being struck by the frequency with which the fibula is cut longer than the tibia. This constitutes an obstacle to successful fitting. The fibula bears pressure on its end very ill, and often it wobbles about and is insecure.

Although many patients with Syme's amputation ask to have one performed higher up, it is deserving of its great reputation. If properly done it gives a painless weight-bearing stump. The bones should be sawn through well above the internal malleolus so as to avoid too bulbous a stump, and care should be taken to make the section at right angles to the long axis of the whole leg and not at right angles to the often incurved lower fourth. Otherwise a varus stump is likely to result. Too low a section leaves no room for a strong transverse ankle-joint, and a too voluminous heel-flap means an unsightly artificial foot and boot.

Of Pirogoff's amputation our experience at Roehampton is small and unfavourable. If the os calcis is not united to the tibia by bone it will sooner or later tilt over, and cause pain, and in any case the stump is too long for the fitting of the best type of foot.

Chopart's amputation gives a good bearing surface, but generally the calf muscles pull up the heel and tilt the lower end downwards, and painful pressure on the scar results. The stump is too short to give a spring to the gait, and it is wellnigh impossible to fix any prolongation on to it. It has no advantage over a Syme, and I would submit that if the metatarsus cannot be saved nothing below a Syme is worth doing.

In conclusion, let me disclaim all intention of laying down the law on this subject. I offer the foregoing opinions for what they are worth as the result of the impressions made upon my mind by what I have observed at Queen Mary's Convalescent Auxiliary Hospitals.

During the past two years, and particularly during the past eight months, I have had exceptional opportunities of studying the results of other men's labours, and I have the greatest admiration for the excellent results achieved, often in most unfavourable circumstances.

DEMONSTRATION.

BY

R. C. ELMSLIE, M.S.LOND., F.R.C.S.ENG.,

MAJOR R.A.M.C.(T.),

SURGEON TO QUEEN MARY'S HOSPITALS, ROEHAMPTON, AND ORTHOPAEDIC SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, LONDON.

WHEN the hospital for fitting limbs at Roehampton was started in the summer of 1915, not only was the supply of artificial limbs from limb-makers in this country totally inadequate for the requirements brought about by the war, but the types of limbs available were by no means perfect, so that a very great deal of experimental work had to be done, more particularly upon artificial arms. The limbs demonstrated were all provided at Roehampton, and, without attempting to illustrate every type of limb in use, represented a series of typical examples of the work there.

As far as the arms were concerned, they showed an immense mechanical advance upon the very elementary types alone available in London at the beginning of the war.

The function of an artificial leg is to give good stability in standing and walking and a natural gait. Hence the important points are: The way in which weight is borne upon the leg; the way in which the leg is built to secure stability; and the way in which the knee and ankle are controlled. A stump may take its bearing either upon its termination (end-bearing) or upon the bony prominences around the proximal joint. End-bearing is a quantity varying not only between stumps at different levels but also in individual stumps at the same level. In general, end-bearing, either complete or partial, may be expected when the bone section is through cancellous bone, when the bone is covered with thick skin and muscle or fascia, and when the skin over the stump is itself naturally adapted to weight-bearing. The type of end-bearing stump is that given by Syme's amputation. The other bearings used should be those upon the tuberosity of the ischium and upon the head of the tibia. Although a certain amount of bearing may be taken by fitting the stump tightly and so getting circumferential pressure upon it, yet this must not be trusted to any great extent, as by this method the skin is apt to be stretched tightly over the end of the stump, and if the scar is terminal or the skin thin this may result in ulceration.

POINTS IN THE FITTING OF A LIMB FOR AMPUTATION: LOWER LIMB.

Thigh.

For amputation through the thigh the limb is generally suspended by a sling over the shoulders, the lower end of which is attached to the leg below the knee either directly or by passing over a pulley. In this way it acts as a knee-extending mechanism. In short stumps, however, this is insufficient to enable the stump to remain securely in the bucket and to control the limb; therefore a pelvic band is added. The mechanism used to extend the knee is of two sorts. The older one is by the use of a spring, either of rubber or of steel; it should act in such a way that the knee is only extended by it from the right angled position; if it acts from a position of greater flexion than this it will prevent the man from sitting comfortably with a flexed knee. The second method is by the use of the sling from the shoulders, which pulls upon the front of the leg piece when the shoulders are raised or when the weight of the swinging limb comes upon it, thus extending the knee. The stops which limit the movement of the knee in both directions must be so strong as to be unbreakable even when the whole weight of the body exerts its maximum leverage upon them. The ankle mechanism is a point in which the present limbs almost all show a difference from the Anglesey leg, which used to be practically the standard pattern of artificial leg in England. In the Anglesey leg a considerable amount of movement was allowed at the ankle, this movement being co-ordinated with that of the knee by an artificial tendo Achillis. In the present types of legs the movement allowed at the ankle-joint is small in range (only about 20 to 30 degrees), and this movement is stopped by the compression of springs, usually of rubber, but sometimes of steel. The smallness of the range of movement is not found to interfere with walking—in fact, the walk is quite good if there is no movement at all.

Correct building of the limb is important if stability is to be secured. Two points are essential: first, the axis of the knee-joint must be behind the line which represents the centre of gravity of the body when it is erect, and, secondly, the foot must be mounted in slight equinus (20 degrees), and must be prevented from reaching the right-angled position.

The routine material for the construction of artificial leg is still willow, and as a rule the thigh and leg pieces are constructed of single pieces of wood, appropriately hollowed out, the joints being made of steel. It is not an advantage to have very lax joints in an artificial leg; as a rule the joints are lined with a bushing of leather, by adjusting which they can be made stiffer.

Hip-joint.

Hip-joint amputations are fitted with a leather cup, which entirely encloses the stump, fitting it very accurately. It is attached to the trunk by a steel pelvic band,

to it is attached the limb by a hinge joint on the outer side, and by a steel piece which runs around on a quadrant situated upon the under surface of the leather cup on the inner side. It is possible, by placing the hip-joint far forward and the knee-joint far back, to fit a limb which is stable with both hip and knee joints free; but it is customary to fit locks to both these joints, so that the man may walk with one or other free.

Knee and Leg.

In amputations through the knee the lower end of the stump is larger than the part higher up, therefore the front of the bucket must be cut away and filled in by a lacing piece of leather or else an entire leather thigh piece must be used. In either case the leg piece is attached by outside steel joints. For amputations below the knee a wooden bucket is accurately fitted to the head of the tibia, and below the patella; the weight should be borne upon these points, although in exceptional cases it may be necessary to fit a leather thigh bucket reaching right up to the tuberosity of the ischium and taking a bearing there. In short stumps a partial end-bearing can often be taken by stretching a shelf across the bucket at the right level; in some cases it is difficult to stop the stump rubbing up and down in the bucket when the knee flexes and extends, this can be got over by fitting a leather socket closely to the stump and inserting this into the bucket. As a rule, the leg is suspended by a lacing leather corset around the thigh, with lateral steels hinged at the knee. When a man has worn a leg for some time, however, he can often dispense with this, having the leg attached only by a narrow band of leather fastening above the knee to which the leg is hung by lateral straps. If this is done the foot must not be adjusted with too much equinus, as the equinus position of the foot tends to force the knee into a hyperextended position.

Ankle.

A Syme stump is fitted into a leather bucket strengthened with steels on either side and in front, and preferably lacing behind. The ankle-joint works against two rubber buffers as in the other types of leg. It is possible, however, to replace this mechanism by a tendon stop at the back and an anterior accumulator, and this method must be used in Pirogoff and Chopart stumps.

The Best Materials for Artificial Legs.

Two outstanding problems remain in the construction of artificial legs. First, the question of material, important both for strength and lightness, and also because the present method of hollowing a bucket out of a piece of willow requires a workman with very special skill and experience. Many other materials are now being tried—leather, plied wood, wood shavings and glue, celluloid and duralumin. The Geller leg shown at this meeting is an example of an attempt to use duralumin and to work out an easy method of fitting. The second problem is that of making a leg for a thigh amputation which will not give way under the man when his weight comes on the leg with the knee flexed. Such a leg has been recently invented but is still on its trial.

UPPER LIMB.

Artificial arms are a much more difficult problem. In general an artificial arm should be designed to take the place of the left arm in work. It is obvious that it must be adapted to the particular needs of the man, and we must either have a large series of arms at our disposal, or else we must be able to build the arm out of stock parts in a variety of ways. An artificial arm need not be an entirely passive appliance; movements can be transmitted to it by tension put upon cords. In this way three pulls can be exerted: (1) by expansion of the chest, (2) by rounding the shoulders, (3) by elevation of the shoulder. These cords can be used to activate the elbow-joint, to lock and unlock this joint, and to work a mechanical hand or appliance used in its place.

Above Elbow.

An arm for amputation above the elbow must be attached by a harness which passes over the shoulder; this should

limit the shoulder movements as little as possible, so that any considerable enclosure of the shoulder is bad. The arm and forearm parts must be connected at the elbow by a hinge joint with a lock which fixes it securely and prevents movement in either direction. The alignment of the elbow-joint need not be the true one; often if the true direction of the elbow is kept the forearm will only flex straight out in front of the patient; it is more useful for it to flex more across the chest. In the mechanical arm the elbow is flexed by a cord usually activated by the pull given by rounding the shoulders. In this arm the forearm piece has the shape of the natural arm and ends in a wrist plate, to which the hand or other appliance can be attached. It is, however, often not desirable to have the cumbersome forearm thus attached; a worker's arm is made for this reason; in this the forearm is represented by a skeleton of steel, usually a rod, to which appliances can be attached. If a man who has such an arm for work wishes to have a nice-looking forearm and hand, he can adjust a show piece representing these over the skeleton. These two types of arm—the mechanical and the worker's—can be combined by making the elbow mechanical but using a skeleton forearm.

Below Elbow.

For amputations below the elbow a simple socket is used connected to an arm corset by lateral steel joints, or, in the case of longstumps, by lateral leather straps. In a new arm made by Williams of Swansea a very simple method of fitting is adopted, the elbow is kept permanently slightly flexed, the socket is fitted to the forearm stump and held on by a continuation upwards of firm leather which laces around the condyles of the humerus; this gives a very secure hold for a working arm.

Shoulder.

In amputations through the shoulder a close fitting over the shoulder is necessary; there may be a shoulder-joint inserted, but this is usually omitted. In order to allow the arm to point in various directions a movement of rotation around a vertical axis is allowed in the arm above the elbow.

Wrist.

In wrist amputations and other amputations low down in the forearm it is important to preserve the movements of pronation and supination. It may be possible to do this by omitting the steel joints at the elbow, but if this is not possible the movement can be secured by the pronation arm made by Hobbs, in which ball-and-socket joints allow the forearm socket to rotate upon the elbow.

For working men appliances fitted to the wrist plate are generally more useful than a hand. The number of appliances made is very large; they may be divided into the following classes: (1) Simple hooks, rings, and grips, without movement. (2) Similar appliances in which there is mobility in one or more directions representing wrist movements. (3) Grips opened or closed by the pull of a cord from the shoulder. Many of the appliances invented by Adams, Hobbs, and Anderson will be seen on the arms worn by the men present.

The hand is not so useful in mechanical work as the appliance, but for men in professional work a good hand is essential. In most cases the hand supplied is a simple one with a spring grip to the thumb and often with the ring and little fingers curved into a hook and reinforced for carrying. But mechanical hands are possible and useful for certain men. The first essential in a mechanical hand is that the grip should not be a simple spring grip, which will always be forced by a very slight leverage from without; the mechanism should be such as cannot be forced except by breaking the hand. Such a mechanism has been invented in a very simple and light form by Hobbs, and adapted to a number of different shaped hands. In order that the hands or appliances may be removed at will, and replaced by others, it is essential that they should all be detachable. For long at Rochampton, whilst insisting upon detachability, we obtained it by screwing in the appliances, using a screw of standard size. But it is evident that quick detachability will be desirable; for this reason the screw method is being replaced by others. Simple methods giving quick detachability will be seen in Hobbs arms.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

GOLD-CROWNED TEETH AS A SOURCE OF DANGER.

It appears to me that the indiscriminate crowning of teeth with gold, as is frequently done by dentists nowadays, is often attended with a considerable amount of risk. I have seen many cases where the patient's health has been seriously affected by teeth being crowned which ought to have been extracted, and I have no doubt that other general practitioners have had a similar experience. A case which I have recently had illustrates this.

In April last I was consulted by a man, aged 87, who was extraordinarily strong and active for his years, and walked regularly from four to six miles a day. He told me that he had a general feeling of malaise, and that he had frequent pain in a left lower molar which was crowned last year, and that five other teeth which had been crowned within the last few years had broken off or been extracted. I found the mouth in a septic condition, with pyorrhoea affecting the seven remaining front teeth in the lower jaw. He had had all the upper teeth removed and wore a plate. I advised his having all the teeth extracted at once. He rather demurred at this, and I tried hydrogen peroxide and mouth-washes, but soon the submaxillary gland became swollen and painful, so on May 13th I called in a consulting surgeon, who at once said that all the teeth must be taken out. This was done, and an abscess with very offensive pus was found under the crowned molar. It was hoped that with suitable treatment of the mouth improvement would take place, but the pain and swelling increased, and in June, under local anaesthesia, the gland was incised, scraped, and plugged with gauze, and a quantity of pus and broken-down glandular substance evacuated. The patient did not improve and the swelling increased and became very hard, so much so that it was a question whether the disease was not malignant. A superficial cervical gland which had become affected was removed and examined, but showed only inflammatory changes. He became slowly weaker and died on September 21st. Up to within three weeks of his death he had been able to go about, but after that took to his bed. The temperature chart for the last three weeks was typically septicaemic. The whole growth was removed after death and examined with the same result as before.

I think there is no doubt that had those teeth been removed at first, instead of crowned, the patient might have been alive to-day.

Portmadoc, Wales.

Reports of Societies.

MODERN ARTIFICIAL LIMBS AND THEIR INFLUENCE UPON METHODS OF AMPUTATION.

A DISCUSSION on this subject, at a meeting of the Medical Society of London on October 22nd, when the President, Sir ST. CLAIR THOMSON, was in the chair, was opened by Mr. MURHEAD LITTLE and Major R. C. ELMSLIE, R.A.M.C., whose remarks are reported in full at pages 550 and 553.

Major JOCELYN SWAN, speaking of operation cases sent over from France, asked whether the speakers considered that the secondary amputation should be performed at once, while the limb was still in a septic condition, or whether it should be postponed till healing had taken place.

In reply to the question how long artificial limbs would last, and whether the parts of a limb which were worn out could be renewed by any one except a skilled maker, Mr. LITTLE, after observing that the secondary amputation should be done as late as possible, said that an artificial leg would last about seven years, but probably something would require to be done in about a year and a half. Experience was not yet sufficiently long to enable it to be said how long an artificial arm would last. Many of the men who came back to Roehampton after six months were those who had used them for very hard work. Centres for repair were being started in other towns, which would save the journey to London.

Major ELMSLIE said that the longest time an arm had been in use was one year. He considered that the fitting of an arm was only the first part of the business. The man should then be trained to use it in a general way, and later in a special way, according to his particular trade or occupation.

In addition to the makers named by Major Elmslie the following had examples of their limbs at the demonstration: Messrs. Rowley, Hanger, and the Essential Limb Co. for lower limbs, and Messrs. Blatchford for arms.

WORK FOR MEDICAL WOMEN.

At the annual meeting of the London Association of Medical Women on October 9th, Lady BARRETT, in her presidential address, said that the Association of Registered Medical Women had originally been formed to give medical women an opportunity for discussing medical subjects when the doors of other societies were closed to them. Though this was no longer the case, and though the best work in the future would be done by men and women together, there was definite work which might with advantage be done in a society for women only: (a) to discuss and express considered opinion on suggested legislation likely to affect the health of women, and (b) to work systematically at those subjects in which women had unique or sole facilities for obtaining data hitherto not available. Lady Barrett instanced as an example of the first group the proposed Ministry of Health as one of those subjects of vital interest in matters particularly affecting women, but the greater part of her address was taken up in discussing three of the subjects in which women had special facilities for obtaining experience: (1) The supervision of the health of industrial women; (2) venereal disease in women and children; (3) the care of maternity. At the present time a very large number of medical women were being employed to look after the health of industrial workers. The women's army behind the lines in France and the women replacing soldiers in England were now examined as recruits and their health watched over by a corps of army medical women. The munition workers throughout Britain, as well as the thousands of factory workers of all kinds doing war work, had medical women in charge so far as they were obtainable, and for some time past the girls in public and private schools had more and more come under constant medical supervision by medical women. Up to the present time we had no large statistics or careful records showing the effects of industrial employment of various kinds on the general health of women, or on such special functions as menstruation, pregnancy, parturition, lactation, etc. Lady Barrett said that medical women ought to feel gravely responsible for the success of the present efforts to control venereal diseases; but to approach this subject with any hope of success meant far more than the isolated work of different members in conducting out-patient clinics or helping in educational work; concerted thought, free discussion, and co-operation were needed. The care of maternity demanded the special consideration of women, although it was not to the same extent directly in their hands. The nation required both work and babies, and women had to supply both. The two popular ideas, that pregnancy was not compatible with health and that "in sorrow shalt thou bring forth children," should be abolished. Research should produce anaesthetics suitable for all cases of labour; more hospital accommodation was needed both for pre-maternal cases of illness and for administering anaesthetics during labour, so that in time it might be possible to secure painless labour for every woman. Various non-medical bodies were expressing very decided opinions as to how the needs for maternity should be met. It was surely more than fitting that medical associations, and perhaps particularly a women's medical association, should express the considered opinion of the majority of its members on this important subject.

Reviews.

TUMOURS, INNOCENT AND MALIGNANT.

A NEW edition of BLAND-SUTTON's masterly book *Tumours, Innocent and Malignant*,¹ serves as a useful reminder of some fundamental truths of the cancer problem which are apt to be forgotten. The preoccupation of specialists, as well as the lay public, with the more

¹ *Tumours, Innocent and Malignant: Their Clinical Characters and Appropriate Treatment.* By Sir John Bland-Sutton, F.R.C.S. Sixth edition. London, New York, Toronto, and Melbourne: Cassell and Co., Ltd. 1917. (Demy 8vo, pp. 799; 383 figures 21s. net.)

menacing forms of new growth tends to relegate the benign tumours to a position of insignificance which obscures their relation to the malignant forms, a relation which it is essential to bear in mind if the problems of new growths are to be envisaged as a whole. The impossibility of effecting a hard and fast separation of benign from malignant tumours still remains at the present time, and this useful work of reference is valuable in that it supplies a connected summary of clinical characters, naked-eye appearances, and microscopical structure, all of which together are still essential to the definition and diagnosis of new growths, whether innocent or malignant. The new edition has been enlarged and many new figures added. The only serious defect in an otherwise excellent book is the absence of low-power histological illustrations, such as form so valuable a feature of Borst's atlas.

Difficulties of definition and diagnosis do not trouble the authors of two other volumes dealing with the subject of cancer. In *Cancer: Its Cause and Treatment*,² Dr. L. D. BULKLEY puts forward the conception of cancer as a disease of metabolism, to be cured by a rigid vegetarian regimen and increased elimination. In the other book, *The Cancer Problem*,³ Mr. GREEN by a statistical study seeks to defend his theory, to which we have called attention on previous occasions, as to the relation of sulphur and smoke in the atmosphere to the incidence of cancer in the inhabitants of various districts.

PSYCHO-ANALYSIS.

A SECOND edition of the English translation of Dr. C. G. JUNG'S *Collected Papers on Analytical Psychology* has been published.⁴ A review of the first edition appeared in the JOURNAL of June 24th, 1916. The editor, Dr. CONSTANCE E. LONG, in a preface to this edition, states that from this work and from another work by Dr. Jung, a translation of which was published in America in 1916, with the title *Psychology of the Unconscious*, a reader will obtain a fairly complete picture of the scientific and philosophic standpoint of the leader of what she calls the "Zürich school" as contrasted with the Vienna school (Freud). To many students of the unconscious it will, she thinks, be a relief to find another aspect than that of "a wild beast crouched, waiting its hour to spring," which has been used as a succinct summary of the Freudian theory. The new edition contains two new chapters in which Dr. Jung develops his ideas on introversion and extroversion. He agrees with Freud in regarding the neuroses as the result of repression, but differs as to the origin of repression. He finds it to lie not in sexuality *per se*, but rather in man's natural tendency to adapt himself to the demands of life one-sidedly, according to his type of mentality. "The born extrovert adapts by means of feeling, thought being under repression and relatively infantile. The introvert's natural adaptation is by means of thought; feeling being more or less repressed remains undeveloped. In either type the neglected co-function is behind the adapted function. This inequality, operating in the unconscious, brings about a conflict, which in certain subjects amounts to a neurosis, and in others produces a limitation of individual development. This view shifts the interpretation of repression on to a much more comprehensive basis than that of sexuality, although there can scarcely be a repression that does not include this instinct on account of its deep and far-reaching importance in man." We have given this rather long quotation as the fairest way of conveying the impression the editor has herself obtained of Jung's theories.

THE FUNDUS IN BIRDS.

DR. CASEY ALBERT WOOD, professor of ophthalmology in the University of Illinois, has produced a fine monograph on *The Fundus Oculi of Birds*,⁵ with many beautiful coloured plates from drawings by Mr. Arthur W. Head.

² *Cancer: Its Cause and Treatment*. By L. Duncan Bulkley, A.M., M.D. New York: P. B. Hoeber. 1917. (Cr. 8vo, pp. 282. 1.50 dollars.)

³ *The Cancer Problem: A Statistical Study*. By C. E. Green, F.R.S.E. New edition. Edinburgh and London: W. Green and Son, Ltd. 1917. (Imp. 8vo, pp. 149; 1 plate, 29 figures.)

⁴ *Collected Papers on Analytical Psychology*. By C. G. Jung, M.D., J.L.D. Authorized translation, edited by Dr. Constance E. Long. Second edition. London: Baillière, Tindall, and Cox. (8vo, pp. 492. 15s.)

⁵ *The Fundus Oculi of Birds, especially as Viewed by the Ophthalmoscope: A Study in Comparative Anatomy and Physiology*. By Casey Albert Wood, M.D., F.Z.S. Illustrated by 145 black and white drawings and 60 coloured plates from paintings by Arthur W. Head, F.Z.S. Chicago: The Lakeside Press. 1917. (Dble. sup. roy. 8vo, pp. 200. 3 guineas net.)

The main purpose of the work is to give such a description of the intraocular appearances and the methods employed in viewing them as will enable ophthalmologists and zoologists to further this study by examining for themselves the fundi of birds. The text and atlas are on a very comprehensive scale, and together form a volume of unusual merit.

The author justifies the elaborate nature of the work by his statement that "the examination of the eyes of birds is a study of the most advanced and most varied apparatus for the highest expression of vision known to any vertebrate class," and claims that ophthalmoscopic examination of the avian eye gives valuable information as to the function of sight in general and the eyesight of birds in particular. He maintains, further, that the appearances of the organs and tissues thus made visible are so characteristic that it is often possible to recognize a species by viewing its fundus oculi. In healthy wild birds these appearances are so constant for each species that they may well furnish independent data for classification. The author believes that the coloured drawings made by the artist faithfully represent not only the varied and beautiful tints but also the complex tissue formations revealed by the ophthalmoscope.

The volume represents the work of ten years in a field of research hitherto scarcely explored, and we believe that the drawings, taken from life by the direct ophthalmoscopic method, are the only series published in book form.

MEDICAL AND SURGICAL APPLIANCES.

Glazed Radium Applicators.

IN the April number of a periodical called *Radium*, published at Pittsburg, Pennsylvania, one of the editors, Mr. Charles H. Viol, Ph.D., gives a description of a glazed radium applicator devised in the Radium Research Laboratory of the Standard Chemical Company. As is well known, the Radium Institute in London, and also French institutions, have used applicators, constructed by mixing the radium salt in a suitable varnish spread on a metal support and allowed to harden. It was found by the company mentioned that such varnish applicators were liable to deteriorate rather rapidly, whereas glass tubes could be used to hold radium without any such effect being observed. Applicators have now been prepared using a lead-free glass, and it is found that the absorption of the softer rays is not much greater than in varnish applicators. The absorption is reduced to a minimum by the use of as little glaze as possible. The glazed applicators are prepared by fusing on to a pure silver metal back, approximately 3 mm. thick, a layer of glaze approximately 0.3 mm. thick, containing radium sulphate, the salt being distributed throughout the glazed layer. Examination with a zinc sulphide screen shows that with this method of preparation a slight alpha ray is produced, but the applicator gives a beta radiation of greater intensity than is generally obtained from a varnish applicator having the same amount of radium in the unit area. The glaze is sufficiently resistant to prevent the likelihood of the loss of radium unless the applicator is subjected to extremely rough mechanical treatment, but in order to avoid cleaning as much as possible the makers recommend the use of a thin sheet of rubber tissue over the applicator when it is in use. Glazed applicators can only be made with a flat surface, and those at present manufactured have a surface of 2 by 2 cm. The amount of radium can be varied; when it is contained to the extent of 5 milligrams the square centimetre the applicator is called "full strength," when half this amount "half strength," when double the amount "2 x full strength." Glazed applicators have been prepared containing up to ten times full strength, but it is considered that five times full strength is as high as should ordinarily be used; a quarter strength is the lowest recommended for practical use. Inquiries as to these applicators may be addressed to Messrs. Watson and Sons, 196, Great Portland Street, W.1, who are acting as agents for the Radium Chemical Company, of Pittsburg, Pennsylvania.

Income Tax for Investors for Year 1917-1918 (London: Mathieson and Sons; 1917, 1s. net) deals with rates of payment, relief, and repayment. It contains an account of the difficulties the private individual meets in consequence of last February's War Loan, which has introduced the principle of payment of income tax on Government securities by assessment at the rate to which an income is liable instead of payment by deduction at the normal rate before the interest reaches the holder of the stock.

British Medical Journal.

SATURDAY, OCTOBER 27TH, 1917.

THE CONFERENCE OF LOCAL MEDICAL AND PANEL COMMITTEES.

SINCE last year's Conference of Local Medical and Panel Committees some matters of great importance to panel practitioners have arisen; especially has there been a growing dissatisfaction with the amount and method of calculating their remuneration. It has unfortunately become almost a habit of a section of the profession to visit its displeasure not only on the Commissioners but on the Council of the British Medical Association, or particularly on any committee concerned in negotiations, and judging from a number of motions sent in for last week's Conference it was fully expected that the Insurance Acts Committee would have an exciting time. After hearing the explanations of the Committee, however, many of the representatives who came to curse remained to bless, and once more has the Association vindicated its position as the official and generally-trusted mouth-piece of the profession in insurance matters. If the Conference were to have no other effect it should show to Government departments that the profession, guided by the Association, is still a fighting force that must be reckoned with in any legislation, and not, as recent events might seem to indicate, a disunited collection of private individuals each fighting for his own hand.

Unusual interest gathered round the motion for a vote of confidence in the Insurance Acts Committee, because with it was a suggestion coming from several quarters, and at first sight plausibly democratic in character, that in all negotiations panel practitioners would better be represented by some separate organization directly appointed by Panel Committees. An amendment to this effect was, however, lost by 113 votes to 16. On the other hand, an amendment deprecating the creation of new bodies as tending to weaken the forces of the profession was carried, and with this addition, which, in fact, strengthened the original motion, the vote of confidence was carried by a very large majority. The Committee will therefore continue to act with enhanced authority as the spokesman, in consultation with Local Medical and Panel Committees, of panel practitioners in central negotiations. The scheme of nomination of fifteen members of the Committee proposed by the chairman was also carried. This means that the Committee will consist of four *ex officio* members with twelve elected by the grouped representatives of the Representative Meeting, and these sixteen will then elect eighteen other members, fifteen of whom will be nominated by the grouped representatives of Local Medical and Panel Committees, and one from each of the following bodies: the Medical Women's Federation, the Society of Medical Officers of Health, and the Poor Law Medical Officers' Association. The Committee thus formed will then have power to co-opt such a number of non-panel practitioners as will secure that four such practitioners shall be members of the Committee. It was explained that at present, out of thirty-three members on the Committee, twenty-nine are actually on the panel or doing insurance administrative work.

On the report as to action taken by the Insurance Acts Committee since the last Conference its chairman, Dr. Brackenbury, referred at length to two matters: (1) The question of discriminating between munition areas and other areas in the payment of practitioners which the Committee had not found it possible or advisable to carry further, and (2) the treatment of discharged disabled soldiers and sailors. His explanation of the Committee's action in the second matter was evidently regarded as satisfactory. He showed that the arrangements were in accord with the decisions of the last Conference, which definitely resolved that the arrangements for the treatment of these men should be separate from those for the ordinary insured, that the present rate for insured persons is inadequate to meet the needs of this class, that additional money should be set aside for the purpose, and that they should be allowed to go to non-panel practitioners if they choose. The Committee had simply carried out the instructions of the last Conference in all these points. He stated further that notice of the proposed arrangements was given as early as June, and up to September 1st not a single Panel Committee or practitioner had intimated to the Committee any objection to the arrangement. Several amendments were on the agenda paper disagreeing with the arrangement, but an amendment from the London Panel Committee, which called for a withdrawal of the regulations and a return to the ordinary capitation payment pending further negotiations, only obtained 20 votes with 133 against it, and other similar amendments accordingly fell through. Dr. Brackenbury undertook to take steps to secure improvement of the arrangement for mileage under the scheme, and it was finally resolved that, in the opinion of the Conference, the Committee had, in view of the decisions of last year's Conference, made as good an experimental arrangement as was possible; though the Conference was of opinion that the method would be detrimental to the financial interest of the profession unless a careful account be kept and rendered by each practitioner for all services rendered, and that this should be fully explained at meetings in every area.

As to the complicated arrangements for making up the medical pool, Dr. Brackenbury confessed that only an expert could follow them. At the present insurance rate the unit of payment would be about 2s. 4½d. per visit with corresponding rates for other items. The idea which led the last Conference to demand a special method of payment per attendance was that these men would require much more attendance than the ordinary insured. Therefore, under the new arrangement, if a disabled soldier were visited twenty times in the year the practitioner would receive twenty times 2s. 4½d., that is, several times more than he would receive at the ordinary capitation rate. The Committee had received a letter containing a guarantee, which it was considered could hardly have been embodied in the regulations, that the Treasury would make up the pool to allow of the insurance unit being paid in full without any deductions. If by any chance it should be found, which is extremely unlikely, that, owing to various disturbing factors to which the Insurance Acts Committee drew attention in its letter accepting the new arrangement, these men require less attendance than the ordinary insured, the arrangement could be revoked. The outcome of the discussion is, then, that the advice of the Insurance Acts Committee that the profession should accept the arrangement still stands good, it being understood that it is only experimental. At a later stage of the meeting it was resolved that as a

number of disabled soldiers and sailors would undoubtedly be referred to voluntary hospitals for special treatment, the medical staffs of such hospitals ought to be paid at an agreed schedule rate for their services apart from any charges made for maintenance by the governing bodies—a policy which had already been strongly urged on hospital staffs and governing bodies by the Association.

Considerable attention was paid to the claims of rural practitioners. It was recognized that they ought to be properly represented on all official committees, and the Insurance Acts Committee was requested to see that in all negotiations their status should be considered as distinct from that of practitioners in industrial and city areas.

The scheme for collective bargaining came in for some criticism similar to that directed against the constitution of the Insurance Acts Committee, but the scheme was carried with only a few dissentients, with a slight amendment which makes it necessary for the Committee to consult Panel Committees before agreeing to any alteration of the regulations. The resolution which was passed pledges the Panel Committee representatives at the Conference to adhere to the scheme, and instructs the Insurance Acts Committee to endeavour to get all Panel and Local Medical Committees loyally to support the Committee if it should be necessary to put the scheme in operation. There is no doubt that if loyally observed the scheme will place a most potent weapon in the hands of the profession in all negotiations with the Commissioners or the Government.

Before the Conference it was evident that there is now all over the country a feeling that the capitation fee must be raised to at least 10s. for the doctors apart from the chemists. For a time after the war began there was a disinclination to demand this, but the uncertainty as to the war's duration, the increased cost of living, and other reasons have made it practically imperative that there should be an early and substantial rise in the rate of payment. The Conference accordingly resolved, with only one dissentient, to demand that the rate should be raised to 10s. from January 1st, 1918, this sum to cover domiciliary treatment of tuberculosis and the increased liabilities with regard to disabled soldiers and sailors, and the Insurance Acts Committee was instructed to negotiate these terms with the Government, and to organize the profession with this object. The suggestion of a war bonus instead of an all-round rise of the capitation rate received but slight support, and was withdrawn. It follows from this that if the 10s. fee be granted, the new special arrangements for disabled soldiers and sailors will no longer be necessary, as these men will be included as ordinary insured persons.

The greatest dissatisfaction was expressed as to the amount actually paid to panel practitioners for the year 1916 compared with what it was considered they ought to have received. The explanatory memoranda of the Commissioners give only a rough outline of the procedure adopted to make up the central pool, and the profession is unable to satisfy itself that the procedure is really a fair one. It has only the Commissioners' statement, relying on the Government actuary, that it is as fair as they can devise, but, after all, even experts are not infallible. The Conference, therefore, while protesting against the unfair payments for 1916, instructed the Insurance Acts Committee to ask the Commissioners to allow a small committee appointed by it, with an actuary appointed by the president of the Institute of Actuaries, to see all the figures and particulars of the process of calculation of the central pool, and report on the

whole situation to the profession. The Committee was also instructed to press for an increased mileage grant for rural practitioners.

A number of other matters dealing with details of panel work were referred to the Insurance Acts Committee for consideration, and it was also instructed to consider the question of holding more frequent conferences of Panel Committees.

ACUTE POLIOMYELITIS AND CEREBRO-SPINAL FEVER.

SOME curious points of resemblance in the recent history of acute poliomyelitis and cerebro-spinal fever are brought out by even a superficial survey of the extensive epidemiological and laboratory investigations consequent on the recent epidemics in America and in Europe. In both the comparatively low infectivity of the virus has become recognized. In America discussion has taken place about the nature of the virus of acute poliomyelitis, and the globoid organism described by Flexner and Noguchi has met with rivals in the form of Rosenow's streptococcus¹ and of a pleomorphic bacillus of the distemper group obtained by Horace Greeley² by means of a new culture medium containing lime water. This bacillus caused paralysis in cats, dogs, rabbits, guinea-pigs, and abortive symptoms in the investigator as the result of accidental infection. It forms spores, is a filter passer, and is saprophytic. As it grows well in milk the startling suggestion is made that the great majority of epidemic cases are due to milk-borne infection. During the epidemic of 1916 this possibility was tested and discarded by the Department of Health of New York City, which did not accept either the globoid bodies or the streptococcus as the proved causal organism.³ This divergence of opinion as to the nature of the virus is paralleled in the case of cerebro-spinal fever by the revolt against the orthodox view of the meningococcus and by the substitution of a pleomorphic organism which Hort has so persistently led and Adami has pleaded for. The clinical symptoms of the meningitic form of acute poliomyelitis are so like those of cerebro-spinal fever that confusion has occurred, and it may be remembered that in 1911 Dr. R. J. Reece, assistant medical officer to the Local Government Board, went down to the West of England to investigate a supposed epidemic of cerebro-spinal fever and showed that it was one of acute poliomyelitis.

In 1914-15 the serum treatment of cerebro-spinal fever was disappointing in this country owing to the inertness of the serum then available, and, not unnaturally, it was argued that lumbar puncture alone was the proper treatment, but with the advent of Flexner's and other new serums this conclusion has since been reversed.

The difference of opinion as to the nature of the virus of poliomyelitis is accompanied, though it is not suggested that there is any logical sequence, by opposition to the treatment of the disease in its acute stage by immune serum obtained from a convalescent donor. Neal, Abramson, and others⁴ state that the immune serum was not used much in the great New York epidemic of 1916, as the early experience of its use was disappointing and the reactions induced so severe that it was felt harm might result from

⁴ B. Neal, H. L. Abramson, and associates, *Arch. Int. Med.*, Chicago, 1917, vol. xx, p. 341.

increasing the amount of meningeal irritation. In animals infected with poliomyelitic virus the intrathecal injection of serum aggravated the comparatively slight inflammation of the meninges, and certainly did not do any good. Thus, while intrathecal injection of serum sets up a chemical aseptic meningitis in healthy membranes and in those slightly inflamed, the injection of antimeningococcic serum in cerebro-spinal fever allays the acute meningitis, as shown by the clearing of the fluid.

A MINISTRY OF HEALTH.

THE plain inference from the remarks of the Premier to a deputation from the Joint Committee of Approved Societies and the Conference of the Amalgamated Society of Industrial Assurance on October 11th is that the Government does not intend to give facilities during the present session of Parliament for any measure to establish a Ministry of Health, and this appears to be confirmed by Mr. Bonar Law's statement on October 18th. He said that at present the various difficulties needing to be provided for in the establishment of such a Ministry have not reached any widely agreed solution, and so long as this was the case it was not possible to undertake to introduce a bill. He added that steps were being taken which it was hoped would secure substantial agreement among those actively engaged in the work of national health, and hinted that he might be able to make a further statement towards the end of the present session. The country will sympathize with the Premier's statement that the Government needs all its energies for war work, and cannot turn aside to consider contentious measures. There is, however, a general impression that the mere suggestion to establish a Ministry of Health has aroused so much departmental jealousy that whatever form any bill may take it will meet with strenuous opposition from one department or another. We are forced to the conclusion that the petty fears of this or that department that it may lose some of its prerogatives are standing in the way of what the public, as well as the medical profession, regards as of the most pressing importance. With the best will on the part of all the departments, the transfer of functions will be no easy task; but without that goodwill the transfer, which we are convinced is inevitable, can only be done by a strong Government determined to set aside departmental jealousies.

The National Insurance organizations of the country have put forward a bill which has the merit that it recognizes the difficulty in the immediate transfer of all the functions of the numerous departments concerned. This bill, which only deals with England and Wales, leaving Ireland and Scotland to separate legislation, provides that there shall be a Minister of Health of Cabinet rank with a salary not exceeding £5,000 a year, and that his duties shall be "to co-ordinate the medical and other services for the preservation and improvement of the health of the people, and to direct, assist, and further investigation and research for that object, to exercise the powers conferred by this Act or by Order in Council made under this Act, and to provide for the distribution of such sums as may be voted by Parliament to assist the local health services." The Minister is to be assisted by two salaried Boards of Health—one for England and the other for Wales—consisting of persons experienced in the working of Local Government Board or Insurance services, or chosen on the ground that they represent labour or the medical profession. As to the transfer of functions from

present departments, it is proposed that while certain health functions shall be immediately handed over to the new Ministry, powers shall be taken to transfer other functions more gradually as found expedient by Orders in Council. It is proposed, for example, that there shall be immediate transfer to the new Ministry of all the functions of the Insurance Commissioners except those of judicial or quasi-judicial character, including those mentioned in Sections 66 and 67 of the Act of 1911, which would be transferred to a special body to be appointed for the purpose by Order in Council. The Commissioners with their staff would thus become officials of the new Ministry, which would also have constantly the advice and guidance of a special body appointed by Order in Council and comprising persons having practical experience of National Insurance work. Authority would be taken to make any necessary change in the Joint Committee. It appears to be recognized that the problem of the Local Government Board is more difficult; it is proposed to transfer immediately all the directly medical functions of the Board under the various Public Health Acts, including the power to sanction loans for these purposes, but to leave other functions, particularly those relating to housing, to be transferred later by Order in Council when found expedient. The functions of the Board under the Poor Laws are considered to offer special difficulty. In the first place, the promoters desire that the new Ministry should not commence by being associated with the odium at present connected in the public mind with the very name of Poor Law. Moreover, the medical services of the Poor Law are said to be inseparably connected with other forms of poor relief. It is proposed, therefore, that the Local Government Board should continue to exercise its Poor Law functions until the long overdue reform of the Poor Law has been carried out, as then only will it be possible to bring the whole of the medical services of the community under one co-ordinated local jurisdiction under the supervision of the Minister of Health. The functions of the Board of Education as regards maternity and infant welfare are to be transferred at once and those in respect to crèches later on. It is proposed that the duties of the Privy Council in respect of midwives should be transferred at once and its other medical and analogous functions later on. It is proposed also to postpone until found expedient the transfer of the functions of the Registrar-General, certain duties of the Home Office as to factory inspection, those of the Board of Control as to the care of the insane, and those of the Minister of Pensions as regards the treatment of discharged disabled soldiers and sailors. It is considered that for all these cases of postponed transfer Orders in Council would be sufficient without special fresh legislation. The bill, it is held, should be accompanied by substantial Exchequer grants to be disbursed by the Minister of Health in the promotion of properly co-ordinated local schemes of health development.

An important part of the bill deals with the hospital question, for it would authorize the new Minister to hold inquiries and make orders with a view to constituting hospital authorities for suitable areas, and for placing under a single management hospitals, dispensaries, pathological and other laboratories, and the special medical services. Private hospitals, it is suggested, might be dealt with by voluntary agreement, while other hospitals might be compulsorily included after inquiry. As regards "excessive sickness," it is admitted that Sect. 63 of the Insurance Act has been a dead-letter. It is proposed to repeal it, and in its place to empower the Minister of Health to hold

inquiries as to cases of excessive sickness in any district, and to order the county or district council to perform its duty; if such authority failed, the Minister could authorize the Insurance Committees to perform the duty at the cost of the defaulting authority.

It is specially to be noted that the bill, with few exceptions, is only concerned with the central organization. The difficulty of the problem presented by the powers of local bodies is enhanced by the present unorganized condition of the central departments, and the idea of the promoters is that the central organization must first be put in order before the needed adjustments and developments of local powers can either properly or safely be entered upon. On this account the bill fails to include many of the suggestions made for local organization by the British Medical Association, and in several other respects it does not recognize sufficiently the importance of securing from the outset the sympathy and co-operation of the medical profession. Far too much of the suggested reforms is left permissive, to be carried out or not by Orders in Council at the discretion of the new Minister. For example, competent opinion holds that the medical functions of the Local Government Board under the Poor Laws could be transferred from the outset. It is a matter of the first importance, and if it is to be postponed, as suggested, until the general reform of the Poor Law is undertaken, and even then left permissive, a most important part of the whole subject, affecting the poorer classes of the community, will have been indefinitely and, we believe, unnecessarily delayed. Again, the provisions for the health of expectant mothers are far too loose and indefinite; provision should be made from the outset for the setting up of local statutory bodies for areas of suitable size and containing a proper medical representation. The suggestions as to the compulsory acquisition of hospitals at the discretion of the new Minister are too drastic, and the least that should be done is to allow any hospital the right of appeal, say, to the Charity Commissioners or some other authority having the interests of voluntary hospitals in its care. Provision, too, might well be made that no hospital shall in future be established in any area without full investigation by the advisory committee to satisfy the Minister that the hospital is needed in the area. The proposals with regard to hospitals are incomplete and will not, we anticipate, be supported by the British Medical Association unless they include amendments in accordance with Recommendation G of the Council's annual report for 1917 with further additions put forward by the Association.

It is difficult to avoid the impression that the promoters of the bill have been frightened by the immensity of their task, and to escape difficulties raised by departmental jealousies have avoided dealing by legislation with some of the most important and urgent branches of health reform, trusting that they may at some time be dealt with by the new Ministry. This seems to have resulted in proposals which would make the new Minister an absolute autocrat in all health matters. No hint is given in the bill as to the fate of the general medical profession under the new conditions. Apparently the Minister of Health is to have it in his power to set up any form of medical service he may choose. The promoters of the bill may reply that they did not feel competent to deal with this part of the subject; this is true, but the medical profession will certainly not consent to any bill which does not better define its future position, and especially will refuse to be left to the caprice of any Minister of Health who by an Order of Council may perpetuate the worst form of bureaucracy. The position of the

approved societies is fully and amply safeguarded in the bill, and if the medical profession is not to be more at the caprice of a new department with enormously extended powers than it is now under a multiplicity of departments, it must equally be safeguarded from the very outset. To expect the profession to accept the bill as it stands, even as only the commencement of a much needed reform, is simply to ask it to take a leap in the dark, and while we welcome many of the proposals of the bill as a statesmanlike contribution to a great subject, its shortcomings are so evident that, without very great changes, there is a fear that it may delay rather than hasten the desired reforms.

"WAR OEDEMA."

UNDER the name *Das Kriegsödēm* (war oedema) great attention is being paid at present in the German medical journals to a peculiar disease which seems to have become widespread throughout Germany during the present year. The disease has broken out not only in numbers of the camps occupied by prisoners of war, but also in the large towns. Maase and Zondek¹ give an account of the disease as they have seen it in Berlin. The first cases occurred in January, 1917; males above the age of 40 years have been almost exclusively the sufferers. No noteworthy premonitory symptoms were observed, but suddenly great oedema developed, especially of the lower limbs. The face and scrotum were often affected also, and in a small number of instances ascites and haemothorax occurred. There were no cardiac symptoms, and the urine never contained any albumin. As soon as the patient was put to bed a very marked diuresis at once began, and the oedema quickly disappeared. Remissions and recurrences were fairly common. The composition of the oedema fluid in these cases had been compared chemically with the fluid effusions in renal disease and obstructive conditions such as hepatic cirrhosis. The chief difference found was the high ammonia figures in the *Kriegsödēm*, as contrasted with the two other conditions. The pulse-rate was markedly slowed during the disease, and examination of the blood gave, as a rule, a red count of three to four millions. This condition of anaemia it was thought might probably be ascribed to hydraemia. The occurrence of diarrhoea was fairly common. The authors, in agreement with others, consider the cause of the disease to be underfeeding, especially the diminished quantity of fat. They suggest that toxic products of albuminoid metabolism may cause damage of the endothelial lining of the blood vessels, and so lead to oedema. The high residual nitrogen and ammonia values found in the blood, urine, and oedema fluids were considered to be evidence in favour of this hypothesis. By giving three patients 100 grams of fat daily for a week the authors were able to cure the disease completely without rest in bed or any other remedial measure. Another factor suggested as of etiological influence is the amount of fluid ingested. Owing to the changed food conditions most of the sufferers had been taking a more watery diet than normally in the shape of soups, turnips, and so on. The regulation treatment of the condition consists of rest in bed until all swelling has disappeared, diminution of the daily fluid intake, and bettering as far as possible of the diet. Schiff² states that the disease appeared in Vienna with great suddenness. He gives the usual pulse-rate as from 42 to 56, and states that the amount of urine passed daily during the stage of recovery was commonly 3 to 4 litres. He suggests that this purely war disease has obvious similarities with beri-beri and other diseases depending on failure of vitamins. Numerous authors have described the same disease as it occurs in the camps of prisoners of war, pointing out clearly its cause and the means that may be taken to remedy it when there is the will to do so.

THE ADRENALS IN WAR INFECTIONS.

DURING the last twenty years the ductless or, as they are now called, the endocrine glands have been the subject of much valuable work, followed, it must be admitted, by some fireside speculation, and this year has seen the appearance of a journal entitled *Endocrinology*. The adrenals have had their fair share of elucidation, and an extremely interesting chapter has been provided by the observations and writings of T. R. Elliott, Cannon, and Crile, on the relation of the adrenals to emotion. As the result of anxiety or stress the adrenin is turned out into the blood stream to lend assistance in the struggle for existence, and the adrenal medulla is exhausted of adrenin. The reaction of the gland to infection has also attracted attention, and Elliott showed that in acute infections the lipoids rapidly disappear from the cortex. The war has not entirely arrested work on these lines, for Goormaghtigh¹ has published a preliminary account, from the hospital at Hoegaarde, of the macroscopic and microscopic appearances of the adrenals of seventy cases fatal from infective complications of wounds, in order to throw light on the functional activity of the glands in the presence of infections. In these cases shock and mental distress admittedly played a part so that the changes in the glands, which were removed from the body within an hour of death, cannot be ascribed solely to infection. Relying on the histological appearances Goormaghtigh considers that early in acute infections the adrenal cortex shows degenerative changes, which, it may be pointed out, resemble those figured in Crile's various books, and that the lipoids are removed; in more prolonged infection the cortex exhibits some degeneration and also evidence of considerably increased functional activity, presumably to provide an increased output of lipoids possessing an antitoxic action. The medulla also shows signs of heightened functional activity in acute infections, and from the examination of the adrenals of patients given adrenin hypodermically during life it appears that the activity of the medulla is thus stimulated.

THE ROCKEFELLER HEALTH RESEARCHES.

THE third annual report of the Rockefeller Foundation, the International Health Board (known previously as the International Health Commission), deals with the year 1916. The general summary, which precedes the details of different States and countries, shows that in addition to ankylostomiasis, malaria and yellow fever have been dealt with, and this would seem to indicate that the board is prepared to tackle all tropical disease where the necessity arises. As regards the first of these scourges, ankylostomiasis, it is stated that active measures to control and prevent the disease are now in operation in Kentucky, Louisiana, Mississippi, North and South Carolina, Tennessee, Texas, and Virginia in the United States; in certain West Indian islands—Antigua, Grenada, St. Lucia, St. Vincent, and Trinidad; in British and Dutch Guiana, Costa Rica, Guatemala, Nicaragua, Panama, Salvador, in South America; and in Ceylon and Siam in the East. Such widespread work, properly controlled as this is, and with no lack of funds to support it, is bound to do good, and, though remarkable results cannot be looked for in a few years, nevertheless results will come, all in due time. To ensure this, permanency of the work is essential, as otherwise matters would quickly drift back. The sanitation of many of the small tropical towns and villages at the present day is very similar to that which existed in England a hundred years ago, and only time and much labour will bring them into line with modern sanitary ideas. As many tropical maladies are insect-borne, study of the habits of the insects concerned is essential, and engineering works, large and small, may be required to abolish their different breeding grounds. The importance of collective investigation and organized campaigns in such

a task is manifest, and it is here that the great value of the efforts of the International Health Board lies. The report describes fully the means adopted in the fight against ankylostomiasis. Of great interest also is the work of the Commission appointed by the board to inquire into the problem of yellow fever centres in South America. The report states that the only endemic centre of the disease in South America at present is Guayaquil, Ecuador, though certain sections of Colombia, Venezuela, and the adjacent West Indian Islands are also under suspicion and require close observation. The eradication of the disease, with this knowledge as a guide, is feasible. The report suggests that Mexico and West Africa should similarly be examined. Experiments upon the control of malaria have also been commenced, and these will be extended in due course. Further, a new school of hygiene and public health has been established in Baltimore by the Rockefeller Foundation in connexion with the Johns Hopkins University, and is to be opened this month with Dr. William H. Welch as director. Three main purposes will be served by the new school: first, to furnish trained men on whom the board may draw; secondly, to serve as a training centre to which students from other countries may be sent for instruction; and, thirdly, to provide a laboratory for solving scientific problems which arise. This Rockefeller Foundation is a splendid conception. Untrammelled by questions of expense, its activities are unlimited, and the benefits it can and will bestow upon mankind in the tropics are inestimable. It is a dream the original workers in tropical medicine often dreamt, and it has come true. Finally, a word of congratulation is due to Dr. Wickliffe Rose, its able Director-General, for the work he has already accomplished. Long may he continue to direct its energies.

WOUNDED AND DISABLED MEN IN VOLUNTARY HOSPITALS.

AT a conference summoned by the British Hospitals Association at Westminster Hospital on October 19th, it was resolved, in view of the abnormal advance in the price of provisions and other articles since the rate of payment for the treatment of soldiers was fixed, to make representations to the authorities with a view of obtaining an increase in the payment for the treatment of soldiers in hospitals. An amendment moved by Mr. Bishop Harman to the effect that the accommodation provided for the treatment of soldiers and sailors should not be at the expense of the civilian sick poor was not seconded. Major McAdam Eccles suggested that in reckoning the cost of maintenance the committee should take into account payment for the services of the physicians, surgeons, and special officers on the medical side. The medical profession had come to the conclusion that payment should be made for their services, such payment not to be made directly to the medical staffs but to the lay administration, which would hand to the medical staff a sum over and above the cost of maintenance to deal with as it considered advisable. The meeting expressed the opinion that the scale of charges for the treatment of disabled sailors and soldiers in civilian military hospitals as proposed by the Ministry of Pensions was inadequate to meet the cost, and strongly affirmed the view that the scale of charges should be such as would cover the whole cost of maintenance and include remuneration in respect of professional medical services. The resolutions were referred to the chairman and the council of the British Hospitals Association, to take such action as may be necessary. Mr. Hoare, who attended the meeting on behalf of the Ministry of Pensions, said that the Ministry had taken as a basis of payments what it had ascertained were the ordinary charges made by hospitals to various Government departments and other bodies in the habit of sending patients to general and special hospitals. Possibly, owing to the increased cost of everything, they might

¹ N. Goormaghtigh, *Arch. méd. Belges*, Paris, 1917, tome lxx, p. 697.

be too low, but it was important to get a uniform charge. The Ministry had not hesitated to sanction a higher payment when it could be shown that the sum allowed was insufficient. The Ministry had no intention of setting up institutions in all parts of the country to compete with the large voluntary hospitals, but in the case of institutions for epilepsy, neurasthenia, and tuberculosis, of which there had been a deficiency, it had taken means to increase the accommodation. In estimating the payment to be made to hospitals the Ministry had aimed at defraying the amount of out-of-pocket expenses incurred by the hospital, but the question of the inclusion of every single item in the amount, including remuneration for the doctor, would have to be settled as a matter of the general policy in dealing with hospital management. When a rate of State payment was settled the hospital would, as a corollary, have to satisfy certain conditions if it was to charge for the medical services of the staff as well as for everything else. A large number of discharged men would possibly within a year no longer require hospital treatment, so that in about three years the present problem would cease to be a problem at all. The Ministry of Pensions therefore believed that the question raised was of a temporary nature only.

THE FOOD POSITION IN GERMANY.

We are now able to give some additional and more precise details with regard to rations of bread and potatoes in Germany. The imperial bread ration in Germany is 2,000 grams a week, that is to say, 285 grams a day. The amount actually allowed varies locally. In Berlin it is 1,950 grams a week (278 grams per day), in Hamburg 1,600 grams a week, in Essen 2,000 grams a week. Bread grain is milled up to 94 per cent. The imperial potato ration is 3,500 grams a week, or 500 grams a day. The amount actually allowed varies locally, but is, generally speaking, about the same as the imperial ration.

We have received from Dr. Neil Macleod of Shanghai a cablegram, dated October 21st, stating that he has detected khaki and other material previous to rays by injecting wounds with thin bismuth emulsion. He is sending an account of his observations by mail.

THE Bradshaw Lecture on "The causes of disease" will be given before the Royal College of Physicians on Thursday, November 8th, by Professor Ernest S. Reynolds, Physician to the Manchester Royal Infirmary. The FitzPatrick Lectures will be delivered on November 13th to 15th by Dr. Arnold Chaplin, well known for his studies of the Napoleonic period. The subject he has chosen is "Medicine in England during the reign of George III." The lectures will be given at the college at 5 o'clock each day.

THE MORTALITIES OF BIRTH, INFANCY, AND CHILDHOOD.

A SPECIAL report on the *Mortalities of Birth, Infancy, and Childhood*, just issued by the Medical Research Committee,¹ contains three studies of the mortality in early life by writers whose methods and points of view are similar but not identical.

Relative Importance of Pre-natal and Post natal Conditions.

Dr. Brend's contribution, the substance of which has already appeared in his recent treatise on questions of public health, is devoted to a comparison of the rates of mortality in infancy and childhood obtaining in different types of community. His method is to ascertain whether an alleged causative factor of infant mortality can be found

in operation with at least equal efficiency in districts the rates of mortality within which are strikingly different. Thus, if the sanitary conditions of two towns are equally good (or bad), but the death-rates of children are different, he concludes that sanitation is not an efficient cause. This process leads him to conclude that the "excess (of mortality) is due to some factor or factors in industrial towns, the centres of large cities, and mining areas, of which possibly the most important is a polluted state of the atmosphere."

Causes of Infantile Mortality.

Dr. Leonard Findlay's paper is largely concerned with the effect upon infantile mortality rates of welfare schemes, and he provides statistical charts which do not bear out the opinion that such schemes can be proved to have influenced appreciably the movement of the death-rates. On the other hand, like Dr. Brend, he attaches much importance to housing conditions, and remarks that "it hardly seems likely that any number of visits to infant clinics will ameliorate the health of the infant so long as it has to spend its time in unhygienic surroundings. This is well exemplified in hospital practice. Not infrequently children are admitted to hospital suffering from marasmus, enteritis, or bronchopneumonia, and recuperate, and are given back to the parents almost normal children, only to return with a relapse in a matter of a month or even less."

Changes in the Physiological Processes of the Developing Child.

The third paper is by Dr. Brownlee, the Director of the Medical Research Committee's Statistical Department. Dr. Brownlee mainly employs the statistical method, but he emphasizes the necessity of statistical analysis being utilized by those who are something more than statisticians, and have a first-hand knowledge of the objective phenomena. In the first place, Dr. Brownlee discusses the use of graduation formulae and illustrates his argument by the application of such a formula to the study of changes in weight with age. He then applies the method to various diseases or associated morbid phenomena. The results lead him to various interesting and novel conclusions. Thus the death-rates at ages from "convulsions" are effectively graduated by a continuous curve, the decline with age being quite regular. Dr. Brownlee notes that "convulsions" are usually considered to be a symptom rather than a disease, but while concurring with other physicians in this opinion he suggests that the interpretation does not sufficiently emphasize the fact that an essential factor is the nervous instability of the child. In other words, there is an important common factor which gives a unity to the group "convulsions" as distinct from its etiological heterogeneity. Somewhat similar considerations apply to the group of diarrhoeal diseases.

These results support a plea for the more systematic study of the changing physiological characters of the infant and child, since in such changes must be sought the basis of the resemblances noted. Dr. Brownlee's reasoning would lead us to expect that exposure to a bad environment should not operate uniformly at different ages, and, from a comparison of Salford's death-rates at ages with those of other towns and of the Healthy Districts Life Table, it seems that it is at the age of 2 years that children are most affected by an unhealthy environment. "Death rates," Dr. Brownlee remarks, "must therefore be considered in relation to the physiology of development, and not as independent numbers which can be used for comparison without giving consideration to the physiological stability of the growing child."

Dr. Brownlee is, of course, too accomplished a statistician to suppose that the feasibility of graduating accurately certain data by a particular formula proves that the formula describes the real law of development. It is indeed well known that statistics can often be graduated with great accuracy by formulae which cannot be supposed to summarize any such general law. But very often, as Dr. Brownlee observes, extrapolation will reveal the failure. Dr. Brownlee's results are, to say the least, very suggestive.

History.

The three studies are preceded by a short historical note in which Dr. A. K. Chalmers deals with some of the earlier records of mortality (in this connexion Wernicke's mono-

¹ H.M. Stationery Office, Medical Research Committee, Special Report Series No. 10. (1s. 6d.)

graph, *Das Verhältnis z. Geborenen u. Gestorbenen in Hist. Entwicklung*, might be mentioned), and also by a general introduction written in the name of the Medical Research Committee. The Committee points out that the work under notice throws some doubt upon the correctness of popular opinions and proves the necessity of further research, but the following view is emphatically expressed: "In the meantime it would be altogether erroneous to suppose that the plain need for further research and the present partial delay in its prosecution give any ground for postponing practical measures for diminishing the avoidable death-rate. Existing knowledge based upon research work is already almost a generation ahead of effective administration action. We have no need for further inquiry to show that improvements in an admittedly imperfect midwifery service would certainly diminish blindness and death among babies, or that bad housing conditions are a causal condition of much disease in infants, or again that a purer milk supply in cities and districts where it is known to contain habitually the germs of tuberculosis would lessen or abolish an important group of the diseases of children."

Medical Notes in Parliament.

The Medical Service in Mesopotamia.—Sir John Jardine inquired whether as regards the troops at all stations at the Shatt-el-Arab, the Tigris and Euphrates, sufficient provision had been made for medical and surgical treatment, including medicines and appliances, fresh vegetables and fruit. Mr. Macpherson said the General Officer Commanding-in-Chief was responsible that sufficient provision was made for the medical and surgical treatment, including medicines and appliances, for the troops at all stations in any particular theatre of war, and there was no reason to suppose that provision in Mesopotamia was not merely sufficient but ample in every respect. All demands for medical stores were promptly met, and, in addition to the medical stores dépôts in Mesopotamia, a special dépôt had been established at Bombay to facilitate supplies. The supply of fresh vegetables was good and amounted to 67 per cent. of the total vegetable ration. Fruit and dates were also available locally and issued to the troops.

Promotion of Territorial Medical Officers.—Colonel Gretton asked the Under Secretary for War if he was aware that a number of medical men joined the Territorial Forces as medical officers *à la suite* with the rank of captain, that an undertaking was given that such officers should be promoted to the rank of major after eight and a half years' service; if he was aware that this term expired in the case of a number of officers *à la suite* last June, and that no promotions had taken place; and if it was intended to carry out the undertaking. Mr. Macpherson replied that the answer to the first part of the question was in the negative. Officers appointed to the *à la suite* staffs of general hospitals served under different conditions to other officers of the Royal Army Medical Corps, and promotion was not based on any qualifying period. Mr. Keating inquired if the recommendations of the Churchill Commission for the promotion of officers who had served eighteen months, unless adversely reported on, was being acted upon. Mr. Macpherson replied that the promotions were being made as rapidly as possible, and approximately 9,000 officers had already been gazetted. Delay was inevitable in some cases, owing to the reports as to officers' efficiency not having been received from their commanding officers.

Commission on Medical Services in France.—Colonel Gretton asked if the Commission recently sent to examine into the Medical Service of the Expeditionary Force in France had yet reported; if not, when the report might be expected, and if it would be laid on the table. Mr. Macpherson: No report has been received, nor can I say when one will be in the possession of the Army Council. I am afraid that no promise to make the report public can be given in advance.

Royal Army Medical Corps Pay.—Mr. Joynson Hicks asked what was the pay at home and abroad of a captain in the Territorial Royal Army Medical Corps and of a temporary

lieutenant in the Royal Army Medical Corps. Mr. Macpherson replied: The pay and allowances of a captain in the Territorial Force, Royal Army Medical Corps, vary from 19s. to 23s. 2d. a day. The pay of a temporary lieutenant engaged on a contract basis is 24s. a day, inclusive. The captain is entitled to a larger gratuity on cessation, and to other advantages, but the question of the comparative emoluments is under the consideration of the Army Council.

The Education Bill.—The House of Commons has heard with great regret from Mr. Bonar Law that there is now no hope that the Education Bill can be passed this session, which means that it will have to be reintroduced next session. The measure has had a good reception amongst educationalists, but it is understood that opposition has been manifested amongst local authorities to the increased control by the Treasury which is made to condition the intended larger grants by the Treasury.

Officers' Uniform and Equipment.—In answer to Colonel Yate, Mr. Forster announced that a scheme has been prepared for cheapening the cost of officers' uniforms, and it will shortly be published.

Invalid Soldiers' Uniforms.—Mr. Forster has informed Mr. Ferens that soldiers invalided and convalescent could not be allowed to wear their uniform with a band instead of the special invalid uniform, but it was intended that the invalid uniform should be improved in cut and style.

Dental Treatment for Soldiers.—Replying to Mr. Pennefather, Mr. Macpherson stated that before soldiers were sent on foreign service they were examined to see if they required dental treatment, and when it was necessary it was carried out by specially appointed dental officers. Mr. Pennefather asked (1) how many dental surgeons with experience in the treatment of jaw injuries have been sent to the various fronts, and are available for special first-aid treatment of such injuries; and (2) what percentage of dental surgeons not in the army are employed in connexion with dental surgery; and what percentage are engaged in combatant and other duties in which their dental surgical training is of no value. Mr. Macpherson said that the information was unavailable, but the total number of commissioned dental officers was 517. In reply to a further question by Colonel Yate, Mr. Macpherson said that there were no dentists on the war establishment of divisions; such officers were allotted to duties in the field by the General Officer Commanding-in-Chief, with whose discretion it was not proposed to interfere.

War Service Badges for Nurses.—Major Chapple asked whether the War Office in issuing badges of honour to those soldiers who entered the theatre of war in 1914 would consider the claims to a similar distinction of military nurses, whose heroism and devotion to duty were no less conspicuous. Mr. Macpherson replied that all officers and others serving in a theatre of war on the establishment of a unit which fulfilled the prescribed conditions would be entitled to a badge, but he asked those desiring information as to details to await the publication of the regulations on the subject.

Hospital Treatment for Ophthalmia Neonatorum.—In reply to Sir William Collins, Mr. Hayes Fisher said it had been the policy of the Local Government Board to press upon the authorities the great importance of arranging for hospital beds for infants suffering from ophthalmia neonatorum, to be admitted along with their mothers, and he was glad to say that several of the larger local authorities had made such arrangements. He had asked the Metropolitan Asylums Board to provide the accommodation necessary, and he understood that they were prepared to provide two hospitals—one to serve the North of London and the other the South. He added that 50 per cent. of approved expenditure was repaid to local authorities by the Local Government Board out of the Maternity and Child Welfare Grant, and this grant was also available for home nursing.

Exportation of Morphine.—Lord Robert Cecil has informed Sir William Collins that licences to export morphine or cocaine from this country to Japan are not granted except on certificates obtained from the Japanese authorities to the effect that the morphine and cocaine are for actual consumption in Japan or in Dairen and its vicinity, and are for medical purposes only. The Japanese Government has issued the necessary instructions for the prevention of smuggling of these drugs and for the exercise of due control in all places.

Indian Opium for Morphine Preparation.—Replying to Sir William Collins, Mr. Waddle (Secretary to the Board of Trade) said that for the last eighteen months Indian opium had been practically the only description of opium available for morphine manufacture in this country, Persian supplies being relatively insignificant. He gave the following statement showing the total net quantity of opium retained for use and manufacture in the United Kingdom in 1913 and 1916, and the countries from which it was originally consigned.

	1913.	1916.
India	4,824 lb.	437,237 lb.
Persia	35,020 "	82,562 "
Turkey	270,123 "	25,843 "
Other countries ...	45,393 "	15,237 "
	285,320 "	560,679 "

* Exports in excess of imports.

THE WAR.

LOW TEMPERATURES AND SHOCK IN WOUNDED MEN.

THE occurrence of very low body temperatures after gunshot wounds is at present the subject of many investigations in connexion with the study of the causes and treatment of shock; some facts recorded by S. Weil¹ on the subnormal temperatures frequently met with in wounded men are therefore worthy of note.

His observations relate chiefly to the period from December, 1915, to March, 1916, but they were continued during the summer months. In the region in which his experience was gained, owing to heavy artillery fire and bad roads, the wounded did not arrive at the main collecting station (*Hauptbandplatz*) until five to eight hours after injury. The arrangements were so defective that only the last part of the journey, about an hour in duration, was made in covered ambulances, in which the patients were well protected by clothing.

During the months mentioned he found that, whereas only slightly subnormal temperatures occurred in lightly wounded men in the first few hours, in many severely wounded cases the temperature on admission was well below 37° C. (98.6° F.), and in some instances ranged down to as low as 31° C. (87.8° F.). No details are given of the method of recording these temperatures, whether axillary, sublingual, or rectal. His observations led him to believe that the low temperatures depended partly on weather conditions, but not so much on actual cold as on rain and long-continued wetting through of the soldiers' clothes. In February, for instance, the subnormal temperatures were not so extreme as in the rainy periods of December and March. Even in summer prolonged wetting produced a similar result. This observation has been made by others.

Weil states that, as was to be expected, the situation and severity of the wound also have considerable influence on the temperature. He observed very subnormal temperatures occur in any case which had suffered great loss of blood, especially wounds of the chest and compound fractures of extremities. He saw numerous cases of chest wounds, associated with haemothorax, in which the temperature on admission was 33°, 34°, or 35° C. (91.4° to 95° F.). The two lowest temperatures recorded were 31° C. (87.8° F.) in a very severe grenade wound of the foot, and 31.6° C. (88.8° F.) in a man whose foot had been blown off, and who had lost a great deal of blood. Weil had the opportunity of studying the temperature in only two head cases; such injuries, apparently, went to some other hospital. The temperature on admission was in both 37.2° C. (98.9° F.).

Abdominal injuries, even when the patient was much collapsed and in bad condition, did not cause very subnormal temperatures, and no record below 36° C. (96.8° F.) was observed. He did not find the relation between subnormal temperatures and surgical shock absolute. In abdominal cases with severe shock the temperature might be little below normal, while very low temperature readings might be observed in men whose pulse and respiration were little changed.

As regards prognosis, Weil confirms the opinion that a very subnormal temperature is not of itself of bad import if operation be delayed until warmth is fully restored.

Cases of wounds of the spinal cord in the cervical region form a class apart. The temperature in such cases may fall so low that it is difficult to understand how life can exist. Other observers, especially Volkmann, have fully confirmed this statement. Volkmann described a case in which a man, wounded in the cervical spinal cord, lived for twelve hours with a temperature of 24.5° C. (76.1° F.) as recorded by the thermometer he used. In four other cases of wounds of the cervical spinal cord, temperatures of 26°, 27°, 26°, and 26° C., were recorded, but there is no proof that the thermometer was correct. In another instance of cervical injury the man lived for five days with a temperature which, it is believed, never exceeded 28.3° C. (82.9° F.). The association of very low temperatures with wounds of this kind is so characteristic that a diagnosis of spinal cord

injury may, it is thought, at times be made almost from this symptom alone. Weil records one such case, sent down as "hysterical paresis," in which the small entrance wound of a machine gun bullet had been missed by the surgeon in the forward area. In one case of injury to the spinal cord Weil was able by intensive warming to bring up the temperature, within twenty-four hours, from 26° C. to 39° C., a change of 13° Centigrade, or 23.4° Fahrenheit, or so he believes!

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Missing.

SURGEON PROBATIONER W. C. HOLDSWORTH, R.N.V.R.

Surgeon Probationer W. C. Holdsworth, R.N.V.R., was reported as missing, feared killed, in the casualty list published on October 17th. He was lost in H.M.S. *Begonia*, a mine-sweeping sloop.

ARMY.

Killed in Action.

LIEUT.-COLONEL J. J. NICHOLAS, A.A.M.C.

Lieut.-Colonel James Joachim Nicholas was born in the Riverina district of New South Wales in 1890. After graduating M.B., B.S. with high honours at Melbourne University in 1911 he served as house-surgeon and registrar at the Melbourne Hospital. He was an enthusiastic member of the Commonwealth Military Forces before the outbreak of war, and early in August, 1914, was gazetted as captain to No. 1 Australian Light Horse Field Ambulance. He proceeded overseas with this unit and saw service with them at Anzac. On January 4th, 1916, he was promoted major and transferred to the 3rd Australian Field Ambulance with whom he saw service in France. In December of the same year he was appointed D.A.D.M.S. to the 1st Australian Division. Some two months before his death he was promoted to the rank of lieutenant-colonel and was the youngest ambulance commander in the A.I.F. On September 20th, when making an inspection of a dressing station, he was struck by a shell and killed instantly. He possessed a strong personality and throughout his life showed keenness, initiative, and enthusiasm. His death is deeply regretted by all who knew him.

CAPTAIN G. S. ELLIOTT, A.A.M.C.

Captain G. S. Elliott, Australian Army Medical Corps, was reported as killed in action, in the casualty list published on October 18th.

CAPTAIN E. T. GAUNT, R.A.M.C.

Captain Eric Thomas Gaunt, R.A.M.C., was killed in action on October 9th, aged 33. He was the second son of Dr. J. P. Gaunt, late of Alveschurch, Worcestershire, and was educated at King Edward's School, Birmingham, and at the university of that city, where he graduated M.B. and Ch.B. in 1908. After filling the posts of resident obstetric assistant at Queen's Hospital, Birmingham, and of house-physician, assistant house-surgeon, and house-surgeon of the General Hospital, Birmingham, he entered the army as lieutenant on January 28th, 1910, and was promoted to captain on July 28th, 1913. When the war began he was stationed at Malta, and went to the front in 1915.

CAPTAIN O. HOPKINS, A.A.M.C.

Captain Odo Hopkins, Australian Army Medical Corps, was recently killed in action by a shell. He was the son of Dr. George Herbert Hopkins of Brisbane, Queensland.

CAPTAIN R. H. SPITAL, R.A.M.C.

Captain Robert Haig Spital, R.A.M.C., was reported as killed in action, in the casualty list published on October 20th. He was educated at Aberdeen University, where he graduated M.B. and Ch.B. in 1905, and acted as junior demonstrator of anatomy. After trying practice at Whaley Bridge, and at Gorton, Manchester, he settled at South Bank, Yorkshire. He took a temporary commission as lieutenant in the R.A.M.C. on October 10th, 1914, and was promoted to captain on completion of a year's service. He received the Serbian Order of St. Sava. 5th Class, in May, 1916.

¹ *Muench. med. Woch.*, No. 37, September 11th, 1917.

CAPTAIN A. G. WHITEHORNE-COLE, R.A.M.C.

Captain Arthur George Whitehorne-Cole, R.A.M.C., was reported killed in action, in the casualty list published on October 17th. He was educated at St. Mary's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1906, after which he acted as clinical assistant at St. Mark's Hospital for cancer and other diseases of the rectum and at the London Cancer Hospital successively. Early in the war he went to France as senior surgeon of an allied forces base hospital, and subsequently took a temporary commission in the R.A.M.C.

LIEUTENANT R. G. HILL, M.C., R.A.M.C.

Lieutenant Reginald Gordon Hill, M.C., R.A.M.C., attached Coldstream Guards, was killed in action on October 11th. He was the son of Mr. G. W. Hill of Highgate, and was educated at St. Bartholomew's Hospital, where he gained the junior entrance scholarship in 1906, the junior scholarship in 1907, and the Treasurer's prize for anatomy in 1907, and was president of the Abernethy Society. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1911, and graduated M.B. and B.S. Lond. in 1913. After acting as senior house-physician at Bart's and as house-surgeon of the Great Northern Central Hospital, and serving as first surgeon of the British Red Crescent Hospital in the Turco-Italian war of 1912, he recently took a temporary commission in the R.A.M.C. He was awarded the Military Cross so recently as September 26th, 1917.

LIEUTENANT D. S. E. MILLIGAN, R.A.M.C.

Lieutenant Donald Samuel Eccles Milligan, R.A.M.C., was killed in action on October 11th, aged 25. He was the second son of Dr. Milligan of Lytham, near Blackpool, and was educated at St. Thomas's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1915. After acting as casualty officer at St. Thomas's he took a temporary commission in the R.A.M.C., and went to France last February. He was attached to the Worcestershire Regiment, and had just dressed a wounded man on a stretcher in a trench when he stood up, and was instantaneously killed by a shell.

Died of Wounds.

LIEUT. COLONEL A. W. F. SAYRES, R.A.M.C.(T.F.).

Lieut.-Colonel Alexander Ward Fortescue Sayres, R.A.M.C.(T.F.), of Hartley, Plymouth, died on October 10th of wounds received on July 17th. He was born in 1867, the son of the Rev. Edward Sayres, rector of Cold Ashton, near Bath, and was educated at Sherborne and at St. Thomas's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1890, the degree of M.D.Brux. in 1896, and the D.P.H. of the London colleges in 1902. After acting as clinical assistant in the ear department at St. Thomas's, as resident clinical assistant at Bethlem Royal Hospital, and as assistant house-surgeon of the South Devon and East Cornwall Hospital at Plymouth, he practised successively at Wincanton, at Woodford, Essex, and at Exeter, finally becoming tuberculosis officer for Stonehouse district under the Devon County Council. For many years he had held a commission in the 1st Wessex (Exeter) Field Ambulance, R.A.M.C.(T.F.), in which he attained the rank of major on March 22nd, 1912.

CAPTAIN G. A. MACFARLAND, R.A.M.C.

Captain George Adams Macfarland, R.A.M.C., died in hospital in London, on October 17th, of septic pneumonia, following wounds received on August 20th. He was the only son of the late Rev. George Macfarland of Belfast, and was educated at Belfast, Dublin, and Edinburgh, taking the Scottish triple qualification in 1903. In the early part of the war he was resident surgeon of the County of London War Hospital, Epsom.

CAPTAIN R. SHERMAN, R.A.M.C.

Captain Reginald Sherman, R.A.M.C., died of wounds on October 10th, aged 30, while serving with a field ambulance. He was the eldest son of the late Arthur Sherman of Greenwich, and was educated at Merchant Taylor's, St. Bartholomew's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1912; and at Caius College, Cambridge, where he graduated M.B. and B.C. in 1914. After acting as extern midwifery assistant, as house-physician, and as resident anaesthetist at Bart's, he took a temporary commission as lieutenant in the R.A.M.C. on December 7th, 1914, and was promoted to captain after a year's service.

Died on Service.

MAJOR H. E. DALBY, R.A.M.C.

Major Herbert Ernest Dalby, R.A.M.C., died at Basra in Mesopotamia on October 15th, aged 49, while serving in command of the hospital ship *Assaye*. He was the son of the late Dr. Dalby of Torquay, and was educated at Charing Cross Hospital, taking the diplomas of L.S.A. in 1899, and the L.M.S.S.A. in 1907. He was in practice at St. Mary Church, Torquay, where he was honorary physician to the Children's Hospital. He had for several years past held a commission in the Special Reserve of the R.A.M.C., in which he attained the rank of major on March 28th, 1912.

CAPTAIN R. STERLING, R.A.M.C.

Captain Robert Sterling, R.A.M.C., died in a nursing home on October 16th, aged 58. He was educated at Durham University, where he graduated B.A. in 1887, M.B. and B.S. in 1892, and M.A. in 1902; he had served for twenty-four years as a missionary, under the Church Missionary Society, at Gaza, in Palestine, and was an honorary canon of the Collegiate Church of St. George in Jerusalem. When his work in Palestine was brought to an end by the war, he took a temporary commission as lieutenant in the R.A.M.C., and became captain after a year's service.

Wounded.

Major W. E. Crowther, Australian A.M.C.

Captain T. B. Brandon, R.A.M.C. (temporary).

Captain M. R. Finlayson, Australian A.M.C.

Captain H. L. Flint, R.A.M.C. (temporary).

Captain W. E. Graham, R.A.M.C.(T.F.).

Captain E. H. Griffin, R.A.M.C. (temporary).

Captain F. P. Grove, R.A.M.C. (temporary).

Captain W. A. R. Haddon, R.A.M.C. (temporary).

Captain W. E. Hallinan, R.A.M.C. (temporary).

Captain F. E. Johnson, R.A.M.C. (temporary).

Captain J. H. Morris-Jones, R.A.M.C. (temporary).

Captain A. Nelson, New Zealand Medical Corps.

Captain J. Tate, R.A.M.C. (temporary).

Captain R. F. Walker, R.A.M.C. (temporary).

Staff Nurse C. A. Davidson, T.F.N.S.

Staff Nurse F. E. McKellar, T.F.N.S.

Prisoner of War.

Lieut.-Colonel G. S. Williamson, R.A.M.C.(T.F.).

DEATHS AMONG SONS OF MEDICAL MEN.

Adams, Robert, Captain Royal Field Artillery, only son of Dr. Adams of Wellington, New Zealand, killed October 6th, aged 29. He was educated at Wellington College, and at Trinity Hall, Cambridge, where he graduated B.A. He was reading for the final Bar examination when he joined the army. He had twice been mentioned in dispatches.

Blake, John Morgan, Second Lieutenant Devonshire Regiment, son of the late Dr. Morgan Dix Blake, killed October 4th, aged 19. He was educated at Blundell's School, and gained a history exhibition at Balliol College, Oxford, 1916, and also a prize cadetship at Sandhurst.

De Lacey, Second Lieutenant West Yorkshire Regiment, attached Royal Flying Corps, only son of Dr. De Lacey, of Newcastle-on-Tyne, killed September 23rd, aged 21.

Hargreaves, James Peter, Second Lieutenant Royal Field Artillery, elder son of Dr. J. A. Hargreaves of Wetherby, Yorkshire, killed on October 9th, aged 19. He was educated at the Leys School, Cambridge, and after matriculating at Emmanuel College, Cambridge, in December, 1916, he went to Exeter as a cadet and obtained his commission in April, 1917. After a short period in Ireland he went to France last July. In the early morning of October 9th he was doing duty as forward observation officer for his battery, and while signalling with a hand lamp was shot by a German sniper and died immediately. His uncle, Captain Herbert Hargreaves, who holds a temporary commission in the R.A.M.C., is serving in France.

Heaton, Ivon, Captain Royal West Kent Regiment, son of Captain C. J. Heaton, R.A.M.C., of Westgate-on-Sea, Kent, died of wounds, October 15th, aged 21. He got his first commission on November 5th, 1914.

Lawrenson, Raymond Fitzmaurice, Captain Cheshire Regiment, only son of Dr. Harman Fitzmaurice Lawrenson, late of Muswell Hill, N. He was severely wounded on August 16th and died on September 5th, aged 27 years. He was educated at Tollington School, Muswell Hill, where he distinguished himself as an organizer of sports. Afterwards he was a popular member of the Saracens Rugby Football Club. After passing the matriculation and intermediate science examinations of London University he studied naval construction, and subsequently joined the staff of Messrs. J. Pollock and Co., shipping engineers. At the outbreak of war he joined the Royal

Engineers, but soon received his commission in the Cheshires. He served for nearly two years in France, part of the time as temporary staff captain.

Locke, William Grace, aged 26, Corporal Rifle Brigade, attached to Trench Mortar Battery, killed October 4th, son of Dr. George Locke, J.P., of Hastings, President of Sussex Branch of the British Medical Association. He was born March 31st, 1891, and was a member of London University and Middle Temple. He joined the army on October 6th, 1914, and gained the Military Medal last summer.

Longhurst, Harold George Fairfax, Lieut.-Colonel Royal Berkshire Regiment, youngest son of Surgeon-Major A. E. T. Longhurst, R.A.M.C. (retired), late King's Royal Rifle Corps, of Chandlersford, Hampshire, killed October 12th, aged 29. He became captain on November 6th, 1914, and major in May, 1917.

Moore, Raymond Cecil Devereux, Second Lieutenant Honourable Artillery Company, killed in action on October 9th, aged 20. He was the elder son of Captain R. Devereux Moore, R.A.M.C.T., of Churchdown, Gloucester, who is also in France. He was educated at Glynarth, Cheltenham, and Cheltenham College. After gaining a scholarship at St. John's College, Oxford, he joined the Honourable Artillery Company as a private. He was recommended for a commission, and was gazetted to his old regiment. He went to the front in July last.

Thomson, Adam Tinning, Lance-Corporal, Cameron Highlanders, the youngest son of Dr. A. Tinning Thomson, of Clachan, Kintyre, and Rowanlea, Greenfaulds, Cumbernauld, reported missing on August 22nd, and now believed to have been killed between August 20th and 24th. He began his career as a lawyer, but relinquished that to enter the medical profession. When the war broke out, he joined the Camerons, and was amongst the first draft of Lord Kitchener's men sent to France, where he saw much service. He was wounded at Loos, and after recovery returned to the front and went through all the Somme battle, but towards its close contracted trench fever and nephritis, and was sent home. He recovered, and returned to the front at the beginning of this year, and was engaged in many of the recent pushes. Although offered he did not accept a commission.

MEDICAL STUDENTS.

Bickley, George Howard, Captain Machine Gun Corps, late Devonshire Regiment, killed October 4th, aged 25. He was the youngest son of Mr. Bickley, of Lyme Regis, and was educated at St. Edward's School, Oxford, and at Pembroke College, Cambridge, where he was studying medicine. He joined the Devon as second lieutenant on October 8th, 1914; went to France in October, 1915; was invalided in the spring of 1916; joined the Machine Gun Corps and went to the front again in February, 1917, becoming captain in September, 1917. He was a noted Rugby football player, having played for Cambridge, the Harlequins, Exeter, and Devon County.

Howe, Frederick William Duncan, son of Dr. J. Duncan Howe (Preston), died on September 8th from wounds received on the previous day. He had intended to enter the medical profession, and passed the College of Preceptors examination in December, 1915, with a junior honours certificate. He then joined as a private in the Loyal North Lancashire Regiment, and at the time of his death was about to apply for a commission. His brother, Lieutenant J. C. C. Howe, R.A.M.C., is in Salonica.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SUPPLEMENT to the *London Gazette* issued on October 18th contained a list of rewards for gallantry and distinguished service in the field. The list contains the following medical officers, who have received the decorations indicated; they belong to the R.A.M.C. unless otherwise shown:

Bar to the Military Cross.

Temporary Captain Oswald John Day, M.C., M.B., R.A.M.C. (M.C. gazetted June 18th, 1917).

Temporary Captain Archibald Fullerton, M.C., M.B., R.A.M.C. (M.C. gazetted January 1st, 1917).

Temporary Captain Noel John Hay Gavin, M.C., R.A.M.C. (M.C. gazetted June 4th, 1917).

Temporary Captain Arthur John Rushton O'Brien, M.C., M.B., African Medical Service (M.C. gazetted February 13th, 1917).

Temporary Captain David James Sheiress Stephen, M.C., M.B., R.A.M.C. (M.C. gazetted July 24th, 1915).

Military Cross.

Captains John Alston (S.R.), Robert Ringrove Gelston Atkins (S.R.), Thomas Herbert Bell, C.A.M.C., William Somerset Birch (S.R.), Arthur Bloom, M.D., John Philip Selby Catcart, C.A.M.C., Franklin Fletcher Dunham, C.A.M.C., David Alexander Ross Haddon, M.B., John Livingston Hamilton,

Charles Llewellyn Lander, Harold Dunmore Lane, Peter MacCallum, M.B. (S.R.), Albert Edward Peel McConnell, Emmet Andrew McCusker, C.A.M.C., Arthur Allan Parker, C.A.M.C., William Barry Postlewaite M.B. (S.R.), James Wilfred George Hewat Riddell, Stanley Graham Ross, C.A.M.C., James Bethune Scott, M.B. (S.R.), William Henry Scott, C.A.M.C., James Walter Woodley, C.A.M.C.

Temporary Captains Philippe Bernard Belanger, Archibald Grainger Bisset, M.B., Oswald Vincent Burrows, M.B., Charles Kingsley Carroll, John Percival Charles, M.B., Andrew Tocher Cunningham, M.B., Lionel Montrose Dawson, M.D., Harold John de Brent, Carl Keating Graeme Dick, James Dickson, Henry Hawes Elliot, M.B., Henry Vincent Forster, M.B., Cosmo William Fowler, M.B., James Harcourt Cecil Gatchell, David Cochrane Hanson, M.B., Arthur Randell Jackson, M.B., Donald John Macdougall, M.B., Douglas Charles Murray Page, William Russell, M.B., Edward Sequier Sowerby, M.B., William Turner, John Alexander Vlasto.

Lieutenants Louis du Vergé, Samuel Vidot (S.R.)

Temporary Lieutenant John Alan Campbell Greene.

The Military Medal has also been conferred upon twenty-two non-commissioned officers and seventy privates in the R.A.M.C., and two privates in the Australian A.M.C.

[Obituary notices of temporary Captains J. P. Charles and J. H. C. Gatchell, who were killed before their awards were gazetted, appeared in our issue of October 20th.]

NOTES.

DISCHARGED NEURASTHENIC SOLDIERS.

THE Local Government Board has issued the following memorandum to boards of guardians at the request of the Minister of Pensions. The President of the Board adds that he feels sure that the guardians and their officers will be anxious to co-operate with the Minister of Pensions in the manner suggested.

Memorandum.

The attention of the Minister of Pensions has been called to certain cases of discharged soldiers suffering from neurasthenia or epilepsy and that symptom of these conditions which is described as "automatic wandering," and is often accompanied by loss of memory. In these cases soldiers have found their way to Poor Law institutions and have there been detained for observation in the mental ward, and in some instances eventually sent to a lunatic asylum.

In cases of this type it is suggested that where any such men are received in a Poor Law institution an inquiry might be addressed to the Special Medical Board for Neurasthenics, at 78, Lancaster Gate, W., to ascertain whether neurasthenia was the cause of discharge from the army, and that that board's reply may be awaited before arriving at a definite conclusion as to the class of case to which any particular man may belong, and especially before any steps are taken to send the cases to a lunatic asylum.

Ministry of Pensions, October, 1917.

DISCHARGED DISABLED FRENCH SOLDIERS.

A congress, to be attended by delegates of provincial associations, is to be held in Paris on November 11th-12th, when a proposal will be made to form a federation of all old soldiers' societies. The scope of the work the congress proposes to undertake is very wide. It will concern itself with all matters relating to the restitution of discharged men to civil life, including immediate assistance for them, the provision and choice of apparatus for them, and their re-education and employment. It will also consider questions concerning pensions, and, in fact, any matter affecting men discharged from the army. Any resolutions adopted by the congress will be referred to the proposed federation for investigation and action. Men discharged from the French army as permanently unfit for any service have already formed a *Fédération des Réformés No. 1 de France*, which recently held a congress at Toulouse. It first resolved that the federation should be administered entirely by men rendered permanently unfit for service by wounds, and then decided that only those who had actually been under fire ought to have the right to wear the chevron of the wounded and the military medal. Afterwards it heard certain explanations from a representative of the Ministry of War.

SURGEON-GENERAL GORGAS has established a board to collect material for a medical and surgical history of the American forces in the war. The board consists of Colonel C. C. McCulloch, head of the Army Medical Library at Washington; Major F. H. Garrison, assistant librarian, who will have direct charge of work on the history, and Captain J. S. Fulton, secretary of the Maryland State Board of Health, who will have charge of the statistical work.

England and Wales.

CURATIVE WORKSHOPS AT CARDIFF.

A SERIES of curative workshops erected by Cardiff ship-owners and coal exporters in connexion with the orthopaedic section of the Welsh Metropolitan War Hospital, at Whitchurch, was opened on October 20th by King Manuel. The new buildings are about 260 ft. long and contain departments for workers in wood, metal and leather, tailoring and cloth working, upholstering and printing. There is also a spacious gymnasium, office, store, and the necessary sanitary accommodation. Captain Alderman Morgan Thomas, who presided, welcomed King Manuel on behalf of the committee and spoke of the keen interest he was showing in the orthopaedic treatment of men maimed at the front. King Manuel, in declaring the buildings open, said that the curative workshops had two distinct aims, one military and the other civil. The country had to think not only of giving back the soldiers to the army, but also of giving back to the nation men who, although they might be crippled or limbless, would still be able to take an active part in the battle of life and become good and useful members of the community. When the war was over, the task of training these men in different occupations would still be huge, and the reconstruction must begin now. In this Cardiff had made a good start, and he appealed for continued support. A vote of thanks to King Manuel was proposed by the Marquis of Bute, and seconded by Mr. J. Herbert Cory, M.P., who said that the least that could be done for the men who were fighting our battles was to provide them with artificial limbs and other devices to enable them to earn their own livelihood in the future. Colonel Lynn Thomas, in proposing a vote of thanks to the donors, said that the sum of £5,500 needed for the erection and equipment of the buildings had been so quickly raised that it had been unnecessary to call together a committee formed at Cardiff Docks under the guidance of Mr. John Cory. The motion was seconded by Colonel Goodall, and, like the previous motion, carried by acclamation.

MATERNITY AND INFANT WELFARE.

On October 18th Mr. Hayes Fisher, president of the Local Government Board, received a deputation from the Urban District Councils Association and the Rural District Councils Association which waited upon him to urge that wider powers should be given to local authorities in England and Wales in regard to maternity and infant welfare, thus bringing them in line with local authorities in Scotland and Ireland. The deputation asked for the establishment of day nurseries for children up to 5 years of age, the provision of maternity and rest homes for mothers, and financial aid for local authorities to provide trained home workers. Mr. Hayes Fisher, in reply, expressed deep sympathy with the objects of the deputation and undertook to ask the War Cabinet to allow him to introduce without delay the bill prepared in 1915 by one of his predecessors at the Local Government Board, Mr. Walter Long. If he received permission, all the powers which they asked would be obtained. He recommended the members of the deputation to devote their energies to getting the bill through, and then to see how far the powers granted were exercised. In this way they might establish a strong case to put before the Treasury for increased grants to necessitous districts.

BIRMINGHAM AND DISTRICT GENERAL MEDICAL PRACTITIONERS' UNION.

The annual meeting of this union was held at the Medical Institute, Birmingham, on October 23rd, when Dr. H. G. Dain gave an interesting address. The report of council for 1916-17 states that the union through its ward meetings has rendered considerable service to the Birmingham Panel Committee and the Birmingham Local Medical War Committee in their difficult task of making satisfactory arrangements for the working of practices of general practitioners who have joined the R.A.M.C. The work of the union in this and in many other matters has been of value to all doctors in Birmingham and district.

Ireland.

LIFE SAVING IN WAR TIME.

MR. ARTHUR DEANE, curator of the Belfast Art Gallery and Museum, has added to an interesting war-time economy exhibition, which has been open during the summer, a room containing exhibits illustrating various phases of welfare schemes. Sir John Byers has written an introduction to the guide, in which he makes some cogent remarks on the waste of life of infants and mothers. It has, he said, been calculated that every hour, on an average, about nine men belonging to the British forces are dying in the war. Twelve babies under one year are in the same time perishing in the United Kingdom, while losses during the antenatal period are responsible for a similar reduction in population. Of the children who enter school, one-sixth show, on medical examination, defects of body or brain. Moreover, one mother, it is calculated, dies to every 259 births in England, one to every 191 in Ireland, and one to every 175 in Scotland. The exhibits illustrate such subjects as the constitution of milk and artificial foods for infants, good and bad feeding bottles, the india-rubber sucking teats which Sir William Jenner used to call "baby killers," house flies and parasites, and many other subjects of interest and importance to mothers. During the time the exhibition is open lectures will be given by various authorities; the first by Sir John Byers, on the problem of maternal and child welfare, and the second, on the mouth, nose, throat, and ears, of the infant and young child, by Professor Symington, who has contributed an interesting set of specimens and diagrams to the exhibition. It comprises also exhibits of clothing, including a set of infant's clothing, lent by the Committee of the Babies' Club, of which Lady Byers is chairman.

"OUR DAY" IN DUBLIN.

"Our Day" in Dublin last week was a marked success. In addition to the 1,000 collectors in the streets, a house-to-house collection was made in the city. The great event of the day was the passing of the pageant through the principal streets of the city. It was not only an education in the progress that has been made during the past three-quarters of a century in the treatment of wounds and disease due to war, but a direct stimulus to take at least a financial share in the care of those who have offered far more than money in the defence of civilization.

An effort is being made by the three southern provinces in rivalry with Ulster to collect £50,000 for the Red Cross.

IMPRISONMENT FOR MILK ADULTERATION.

Last week the Recorder of Dublin heard appeals brought by milk vendors convicted in the police courts for milk adulteration. A milk vendor was sentenced to two months' imprisonment with hard labour for having sold milk adulterated with 14 per cent., 18 per cent., and 49 per cent. of water. The Recorder confirmed the decision but reduced the period of imprisonment to one month with hard labour, as he had some doubt whether in the case of the 49 per cent. adulteration the milk was intended for sale. He approved of imposing terms of imprisonment for this class of offence. It was the only way of dealing with it, for it was nothing less than murder to sell adulterated milk for consumption by children. The appellant had been convicted five times, and fined in sums varying from £1 to £10.

THE Joint Disablement Committee for the South-Eastern District of Scotland has been authorized to erect an orthopaedic centre in Edinburgh, near the School Board technical workshops at Tynecastle. The building will be of a temporary character, and is designed for the benefit of disabled soldiers and sailors who, having been discharged from the army, come under the care of the Pensions Ministry while still needing further treatment and training. The building, it is estimated, will cost between £2,500 and £3,000.

Correspondence.

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.

SIR,—At the end of the excellent account of the meeting held on October 10th, which was published in your issue of October 13th, p. 494, it was stated that the Executive Committee at present is identical with that of the Committee of the Royal Medical Benevolent Fund.

The Managing Committee of the Royal Medical Benevolent Fund, however, felt that the special work of the War Emergency Fund required a committee which should be more fully representative and more competent to deal with the professional questions which would arise. It therefore delegated these duties to a special Executive Committee consisting of the President, Treasurer, Honorary Secretary, two other members of the Royal Medical Benevolent Fund Committee, Dr. G. Haslip and Dr. Leonard Guthrie, to whom have been added Lieut.-Colonel D'Arcy Power, Colonel James Galloway, and Lieut.-Colonel Sir Alfred Pearce Gould, with power to add to their number.—I am, etc.,

G. NEWTON PITT,
Honorary Secretary.

11, Chandos Street, Cavendish Square, W.1.,
October 17th.

THE ETIOLOGY OF TRENCH FEVER.

SIR,—In the BRITISH MEDICAL JOURNAL of October 13th there appeared a paper on the "Etiology of trench fever: a preliminary communication," by Pappenheimer, Vermilye, and Mueller. There was described an organism found in blood films from cases of trench fever, and believed to have been obtained in sections and cultures of excised periosteal tissue and from the circulating blood. Although at the time when the paper was sent in for publication the evidence in favour of the bodies described being living organisms, and possibly related to the production of trench fever, seemed convincing, more extended studies have proved to us that we were mistaken, and that the bodies are in all probability not living organisms.

The organisms described as discoid bodies with a peripheral granule lying free in the plasma or upon the red blood cells have not as yet been found in control cases, but a study of (n) slide in which they were extremely numerous and apparently typical throws doubt upon their significance. In this slide the bodies persisted after repeated decolorization and restaining; but, since they were found at a distance from the blood smear, it seemed obvious that they were not in the blood itself; and when normal blood was smeared over this portion of the slide the bodies appeared to be present upon and about the normal blood cells. It is clear that this observation is sufficient to discredit the significance of the bodies and their interpretation as possible protozoan forms.

In our paper it was stated that when tissue from the excised periosteum and fascia, taken from the tibial region of cases of trench fever, was implanted upon agar slants, there developed a progressive clouding of the media, with the appearance of numerous small bodies somewhat more variable in size than those seen in the blood films, and, for the most part, without a distinct peripheral granule. Further experiments have shown us that there may develop, under conditions which we do not understand fully, a similar clouding with tissue from cases in whom there is no reason to suspect a previous infection with trench fever. Examination of these tubes from control cases shows bodies indistinguishable from those observed in our so-called positive culture. We have come to the conclusion, therefore, that the clouding is due to a precipitation of the agar, and not to the growth of living organisms. To decide the matter finally, suspensions of agar containing the bodies have been injected into four individuals who volunteered for the experiment, and in no case did there develop any evidence of illness. It has been found also that normal blood slanted on agar and allowed to incubate for a sufficient period quite regularly produces a clouding in the depths of the agar which may show, on examination, bodies similar to those described. Whether or not the clouding appears earlier in blood from trench

fever cases we cannot as yet state definitely, but it is evident that the clouding is due to a precipitation in the agar, and not to a growth of living organisms.

Finally, as regards the very similar bodies seen in sections of excised periosteum, we are still in doubt; their significance, however, becomes doubtful in view of the fact that in some sections of control, supposedly normal tissue, we have found granules of similar form and staining reaction rather widely distributed about the blood vessels. These are possibly mast cell granules which have become freed from the cells and scattered through the tissue. However, it will be necessary to study further material before reaching a final decision on this point.

In conclusion, we wish to state that, as a result of our further experiences, we do not at present believe that the bodies described by us are micro-organisms, or related in a causative way to the production of trench fever.—I am, etc.,

ALWIN M. PAPPENHEIMER,
Captain, M.O.R.C., U.S. Army.

France, Oct. 17th.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—We should be glad to have an elucidation of the position in which the matter of attendance upon invalided soldiers and sailors was left by the Conference of Local Medical and Panel Committees last week.

By approval of the report of the Insurance Acts Committee the Conference approved the institution of the present system of payment per attendance from a special pool with a probable extra Treasury grant. This, in our opinion, would mean a very large extra payment for the treatment of these men, an opinion which one of us can support by experience of the working of a system of payment per attendance for ordinary insurance work.

By acceptance of Par. (c) of Motion No. 33 of the agenda, the Conference then proceeded to instruct the Insurance Acts Committee to press for a complete alteration of what they had already approved, and to merge the treatment of this special class with that of ordinary insured persons at an all round capitation fee of 10s.

Whilst this seems to us to give away entirely our case for special payment for a special class, and to use the special claim simply as an additional and unnecessary argument in favour of a well deserved increase of payment for ordinary insurance work (which might well have been pressed for in addition to the present arrangements), our chief object in writing to you is to obtain from our colleagues of the Conference, its Chairman, or the Chairman of the Insurance Acts Committee, a clear exposition of the present position in order that we may be able to report to our Panel Committees. Does the prior resolution stand and is it binding?—We are, etc.,

FRANK RADCLIFFE,
R. G. MCGOWAN.

Oldham, Oct. 20th.

SIR,—May I say, in reply to Dr. F. A. L. Burges, that the Insurance Acts Committee was instrumental in the suspension of the keeping of case records during the war, this same Committee has done much to annul this respite by favouring the new arrangements, which necessitates the use of Form I.S./7.

The Conference on October 18th agreed on the question of increased remuneration; does Dr. Burges think this an "impossible demand"? I feel, and many others agree with me, that the old capitation grant, for all, would be infinitely better than the new regulations.

In reading the result of the meeting on October 18th one must bear in mind that the representatives were those elected some time ago, before this question was before their constituents; thus the question was decided on what may be described as "an old register." The Panel Committees, as they now remain, do not represent—in fact, cannot represent—the views of panel medical men; the question has never been before the electorate of the panel. When it does come up, without a doubt the personnel of the Panel Committees will be changed.—I am, etc.,

Bristol, Oct. 20th.

JOHN WM. TAYLOR, M.D.

Obituary.

SIR PARDEY LUKIS, K.C.S.I., M.D., F.R.C.S.,
DIRECTOR-GENERAL INDIAN MEDICAL SERVICE.

We regret to learn that Sir Pardey Lukis, Director-General of the Indian Medical Service, died in India on October 22nd, at the age of 60. He had a serious illness a couple of years ago, and it was to a recurrence of this malady that his death was due.

Charles Pardey Lukis was a son of the late Mr. W. H. Lukis, and received his medical education at St. Bartholomew's Hospital. He took the diplomas of M.R.C.S. and L.S.A. in 1879, and entered the Indian Medical Service in 1880, being at the top of the list of successful candidates. He graduated M.B.Lond. in 1889, took the diploma of F.R.C.S. in 1890, and the degree of M.D.Lond. in 1904. He was with the field forces engaged in Waziristan in 1881, and in the Zhob Valley three years later. He then transferred to the civil branch, and held various appointments in the United Provinces. He became civil surgeon of Simla in 1899, and honorary surgeon to the Viceroy in 1905. His first connexion with Calcutta was as professor of materia medica, and in 1905 he was appointed professor of medicine, principal of the Calcutta Medical College, and first physician of the College Hospital. He was selected to be Director-General of the Indian Medical Service at the beginning of 1910, and by successive extensions had held this post for nearly eight years, a longer period, we believe, than any previous occupant of the post enjoyed. Lukis, from the beginning of his time in India, gave himself up to the clinical side of his duties with all the remarkable ability and energy with which he was endowed, and continued to keep himself abreast of the progress of medicine and surgery. When he was advanced to the highest administrative medical post in India he was able to show that he had not failed fully to appreciate the importance which laboratory and field research had attained. He used the influence his position gave him to promote the formation of the Indian Research Fund Association, which has already done a great deal for research in India. How much may partly be gathered from the paper read for him at a meeting of the Royal Society of Arts last March and from the speech of Sir Havlock Charles on the same occasion.¹ Lukis was the first editor of the *Indian Journal of Medical Research*, issued by the Research Fund. He was the editor of Ghosh's *Materia Medica* and Waring's *Bazaar Medicines of India* and the author of a manual of *Tropical Hygiene*, a third edition of which, revised with the assistance of Lieut.-Colonel Blackham, appeared a couple of years ago.

The outbreak of war threw a great deal of increased responsibility upon Sir Pardey Lukis. The civil personnel of the service he directed was greatly depleted by the calls of military expeditions sent to Europe, Mesopotamia, and East Africa, and it will be remembered that the Mesopotamia Commission bore testimony to the energy and vigour with which he laboured to remedy defects and shortcomings during the short period for which he was Director of Medical Services in India. The energy displayed and the speed with which new proposals were carried through were highly praised by the Commission. He was commissioner for the St. John Ambulance Brigade in India and chairman of the Executive Committee of the St. John Ambulance Association in India. In these positions he did everything to favour the fine efforts made by the princes and people of India for the relief of the sick and wounded.

Sir Pardey received the C.S.I. in 1910, and was promoted K.C.S.I. in 1911. He became honorary surgeon to His Majesty in 1913. He is survived by his wife, a daughter of the late Colonel John Stewart, R.A., and by one son and three daughters. His eldest son, who gave every promise of following his father's successful medical career, accepted a commission in the London Regiment immediately after the outbreak of war, and was killed in March, 1915.

JOSHUA POWELL, M.R.C.S., L.S.A.,
NEWCASTLE EMLYN, MID WALES.

The death on October 21st of Dr. Joshua Powell, of Newcastle Emllyn, will cause widespread regret in the part of

¹ BRITISH MEDICAL JOURNAL, March 31st, 1917, p. 427.

Wales in which he has so long practised. He was ill only for a short time, the cause of death being pleuropneumonia. He received his medical education at University College, London, and took the diploma of M.R.C.S. in 1874, and that of L.S.A. in the following year. After holding the appointment of house-surgeon to the Royal Free Hospital, London, he settled in practice first at Rhydlewis, the village in which he was born sixty-seven years ago; afterwards he removed to the market town of Newcastle Emllyn, from which centre he carried on a large practice in the surrounding districts of Cardiganshire and Carmarthenshire. He was medical officer of health for Newcastle Emllyn urban district and Llandysul rural district, and was also public vaccinator and certifying factory surgeon. He took an active part in the public work of the district, and was a justice of the peace for the counties of Carmarthenshire and Cardigan. He was a member of the British Medical Association, and had recently vacated the office of chairman of the South-West Wales Division.

Dr. Powell leaves a widow, a daughter, and a son, who is a member of the medical profession. The internment, which took place on October 25th at Twrgwyn, near Rhydlewis, was largely attended. Among those present was Colonel Lynn Thomas, C.B., C.M.G., who was a pupil of Dr. Powell's at Rhydlewis.

Dr. Joshua Powell was a fine specimen of the country practitioner, concealing under a somewhat rough exterior not only a kindness which endeared him to his patients and all the countryside, but also a sound practical knowledge of medicine and surgery, which he took care to keep fresh by constant reading of the newest books, preferring those which dealt with the principles of physiology and pathology. Goitre is very common in that part of Wales, and it was characteristic of Dr. Powell that one of the latest books he read was Major McCarrison's masterly volume on that bewildering subject.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a congregation held on October 18th the following medical degree was conferred:

M.B.—Samuel C. Varley.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on October 18th, the Vice-Chancellor (Dr. A. E. Shipley) presiding, the following medical degrees were conferred:

M.D.—P. Stocks.

M.B., B.C.—K. B. Dickson, R. Francis-Jones.

UNIVERSITY OF ABERDEEN.

The General Council met on October 13th, when it was agreed to request the Secretary for Scotland to make an order continuing in office the four retiring assessors, one of whom is Colonel Scott Riddell, for another year, and empowering the court to deal with any casual vacancies. A report from the subcommittee of the Business Committee, suggesting certain alterations in the status of lecturers and assistants, and providing for their representation on the governing body, was remitted to the committee, as was also a report recommending the establishment of a Faculty of Commerce, after the principal had suggested that the people of Aberdeen, who profited so much from fisheries, should establish a fisheries lectureship in the University.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The following office-bearers have been elected for the ensuing year:—President: R. McKenzie Johnston. Vice-President and Representative on the General Medical Council: James W. B. Hodsdon. Secretary and Treasurer: George Mackay. Convener of Museum Committee: Charles W. Cathcart. Librarian: Harold J. Stiles.

The following gentlemen having passed the requisite examinations have been admitted Fellows: H. H. Christie, J. B. Leather, R. Parsons, M. C. Pruitt, H. A. Rippiner, D. Welsh.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

SURGERY.—*E. F. Deacon, *E. A. Leak, *† I. Liberman.

MEDICINE.—*J. L. D. Buxton, *E. F. Deacon, *A. Magill, J. S.

Mathews, *† G. L. Mitchell, *† J. H. Tighe.

FORENSIC MEDICINE.—J. L. D. Buxton, O. Halstead, J. S. Mathews,

J. H. Tighe.

MIDWIFERY.—G. H. Fitzgerald, O. Halstead, S. G. Mohamed, S.

Robinson, G. E. Spero, T. C. Stephen.

* Section I.

† Section II.

The diploma of the society was granted to Messrs. J. L. D.

Buxton, E. F. Deacon, I. Liberman, and J. S. Mathews.

The Services.

EXCHANGE.

OUR CORRESPONDENT R.A.M.C. serving with C.O.S. France desires exchange to hospital at home—Address, No. 3650, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.2.

Medical News.

SIX beds for the treatment of Bright's disease have been endowed in University College Hospital by Sir Lucas and Lady Ralli in memory of their son, Captain Leo L. Ralli, A.S.C.

FOUNDER'S DAY at the National Hospital for the Paralyzed and Epileptic, Queen Square, W.C., will be celebrated next Friday afternoon, when the civilian and military wards will be open for inspection from 3 to 6 p.m.

DEMONSTRATIONS of specimens of inflammation and gunshot injuries in the Museum of the Royal College of Surgeons of England will be given by Professor S. G. Shattock, F.R.S., on Mondays, November 5th, 12th, and 19th, at 5 p.m.

THE first meeting of the Röntgen Society for the session will be held on Tuesday, November 6th, at 8.15 p.m., at the Royal Society of Arts, when the president, Captain G. W. C. Kaye, D.Sc., will give an address on the part played by x rays in the war, and there will be an exhibition of apparatus.

IN reply to an inquiry by the Automobile Association, the Minister of Munitions has stated that so long as coal gas for motor vehicles is carried as at present, in bags at or slightly above atmospheric pressure and not compressed in steel cylinders, it is not considered that there is any need for restricting the use of coal gas for motor purposes. The Minister goes on to state that if motorists were to use coal gas on any considerable scale it might become necessary at some future time to impose certain restrictions.

THE arrangements of the Royal Institute of Public Health for discussions and lectures before Christmas include the Harben lectures on the "Treatment of infected wounds," by Dr. Carrel, to be given on November 26th, 27th, and 28th, at 4 p.m., at the Institute, 37, Russell Square, London, W.C. Other lectures will be delivered on Wednesdays at the same place and hour, the first to be given by Major Waldorf Astor, M.P., on October 31st, on "Health problems and a State Ministry of Health."

THE mission sent to France by the Rockefeller Foundation to assist in combating the threatened increase of tuberculosis has decided to work in three sections under the general direction of Dr. Farrand. The first section will establish in one of the arrondissements of Paris and in certain large provincial towns a complete antituberculosis organization consisting of dispensaries, clinics, and laboratories, with provision for domiciliary attendance. This section will be directed by Dr. Miller. A second section, under Dr. Charles White, will undertake the distribution of help in kind. A third section, under Professor Gunn, will be concerned with the education of the public: it has already commenced to organize travelling exhibitions, meetings, and cinematograph displays.

THE trial of Dr. George Harry Bishop, B. G. Grantway, and J. Trichter, for conspiracy to defeat the provisions of the Military Service Acts was concluded before Mr. Justice Shearman, at the Central Criminal Court, on October 20th, after a hearing which lasted several days. The allegation was that a drug had been supplied, in the form of pills, to Samuel Augustus Frank with intent to render him, or to induce the belief that he was, permanently unfit for service. Evidence given as to the analysis of the pills showed that they contained dried thyroid gland. The jury, after an hour's deliberation, found each of the prisoners guilty. The judge, in passing sentence, intimated that there was a point of law for the Court of Criminal Appeal. He sentenced Dr. Bishop and Grantway each to twelve months', and Trichter to three months' imprisonment.

AT the monthly meeting of the Staffordshire Insurance Committee it was reported that the Panel Committee had asked the Committee to support it in making representations to the Commissioners that steps should be taken to secure that panel practitioners should be supplied with petrol at pre-war rates. This had been considered by the Medical Benefit Subcommittee, which recommended the Committee to support the application. Exception was taken to the recommendation by several members of the Committee, and it was urged that the doctors who kept a horse conveyance might just as well ask for horse food at

pre-war cost. The recommendation was also opposed by a medical member of the Committee, who thought the correct way was for the doctors to organize for an increase in remuneration. In the end the matter was referred back to the subcommittee.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

E. P. D. desires to hear of a family with children, near London, which would receive a mild case of cretinism in a boy aged 7, with his nurse.

LETTERS, NOTES, ETC.

TETANUS BACILLI IN COURT PLASTER.

SIR JAMES BARR informs us that a good many years ago he ascertained that many specimens of gelatine contained the tetanus bacillus. As gelatine is used in the making of court plaster, the risk of using this old-fashioned remedy must be recognized.

TREATMENT OF VINCENT'S ANGINA.

J. R. W. writes to endorse Dr. Percy Newell's statement (October 13th, p. 502) that the iodine treatment of Vincent's angina is the best. I have, "J. R. W." writes, never yet seen it fail in any of the cases I had under my care in an infectious hospital in France. The cases were kept in a separate ward, and the treatment was discontinued when there were no traces of the spirilla; it seldom took more than a week to get the desired result.

THYROID GLAND DOSAGE.

MR. W. H. MARTINDALE, Ph.D. (10, New Cavendish Street, London, W.), writes, with reference to Dr. Carver's note in the JOURNAL of October 20th, p. 515, to express the opinion that the name "thyroid extract" is unfortunate, and has apparently led some to think that the prescriber intends a dose of equivalent amount of fresh thyroid gland substance. The fresh gland basis ought also, he considers, to be abolished as unsound therapeutically and commercially. He thinks it regrettable that the *British Pharmacopoeia* provides no standard for dried thyroid gland. Though it may be true that the iodine content does not adequately represent the potency of the gland, at the present time there is no other known constituent which could form the basis of assay, and he suggests that the medical man should prescribe dry thyroid gland standardized to 0.2 per cent. organic iodine content. He concludes his note as follows: "The organic iodine content in commercial samples of *thyroideum siccum* (B.P.) may vary from 0.029 to 0.5 per cent. The whole question of standardization of thyroid preparations is thoroughly sifted in the *Extra Pharmacopoeia*, vol. ii, p. 133 et seq., and a simple process of assay is provided. May I add that in your columns, June, 1913, p. 1278, you remarked: 'Standardization in accordance with the amount of dry combined iodine appears to be a wise course.'"

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postae restant* letters addressed either in initials or numbers.

An Address

ON

INJURIES TO THE PERIPHERAL NERVES
AND THEIR TREATMENT.*

BY

SIR BERKELEY MOYNIHAN, C.B.,

TEMPORARY COLONEL, A.M.S.,

CONSULTING SURGEON, NORTHERN COMMAND.

[In the preparation of this paper I have received valuable help from my colleagues on the staff of the 2nd Northern General Hospital, Leeds, Captain Burrow, Captain Daw, Captain Richardson, and Dr. Cuthbert Morton.]

NATURE OF INJURIES.

The lesions of nerve trunks as the result of wounds may be of diverse forms.

I.

In the majority of cases the nerve trunk has not sustained a primary injury. It may be exposed in greater or less degree in a wound of the soft parts with or without fracture. If the wounds are gravely infected and suppuration occurs with, perhaps, necrosis of one or of many fragments of bone, the process of healing may be long delayed, and the cicatricial tissue which results will be of exceeding density. The nerve then may come to lie in the midst of a fibrous mass which, undergoing progressive contraction, presses more and more firmly upon the delicate and tender tissue of the nerve. The nerve trunk is strangled, bereft of its due supply of blood, and becomes in consequence functionless. It is impossible before operation to decide in the severer cases whether such a nerve has or has not been completely divided.

II.

The nerve fibres may not have been directly, or they may have been only very trivially implicated, but the projectile may have passed so near the nerve trunk as to have opened its sheath. The nerve then becomes adherent to the track of the missile, and a mass of fibrous tissue is found firmly welded on to its lateral aspect. Or the projectile, in this case a rifle or machine-gun bullet, may at that period of its flight when it has become steady have cleared through the trunk of a nerve separating the fibres and severing few or none. Haemorrhage within the sheath occurs and a fibrous mass develops in the centre of the nerve, causing it to assume a fusiform appearance. There is then a *central neuroma*.

III.

The nerve may have been partly severed, say in half its diameter, by a projectile, or a fragment of bone. The gap in the nerve is soon filled up by fibrous tissue, which extends widely upwards and downwards and away from the side of the nerve, so that a hard fibrous *lateral neuroma* is found.

IV.

The nerve may be completely severed. In such a case a gap of greater or less length is found between the divided ends. Bridging this interval there may be a connecting strand of fibrous tissue, or a blurred mass of scar material in which both cut ends are lost. In some cases the nerve may appear hard and swollen, and as though its fibres were continuous; but careful dissection will show that there is complete division.

When the nerve has been cut completely across the upper divided end is soon found to present a characteristic bulbous appearance. On section this is seen to consist partly of fibrous tissue and partly of nerve tissue. From the upper end of any divided nerve the axis cylinders grow downwards tirelessly, each one searching out diligently but blindly the lower end to which it seeks to unite. When the quest fails in one direction and an uncongenial tissue is met, the axis cylinder turns in another direction, searching there fruitlessly again, and so twists itself in ceaseless contortion until a tumour, a *terminal neuroma* is formed.

The fibrous mass, often of extreme density, which goes to the making of the bulbous end is probably the reply of tissues to the contact of exposed nerve fibres with them. The peripheral nerves are intruders among the other

tissues of a limb, reaching them by a process of invasion from without. The contact of these nerve fibres with any other tissue is prevented by their closure within a sheath whose function appears to be that of an insulator. The end organs of the sensory nerves may indeed be, as W. Trotter suggests, a special mechanism for isolating the nerve fibres, protecting them from actual contact with the tissues. Whenever the nervous system is injured, by accident or design, as in the operations of trephining and laminectomy, there is always a hasty and adequate attempt to isolate the parts again. There is an intolerance of the tissues for contact with nerve matter or conversely of these with other tissues.

Gosset says that the axis cylinder is very unintelligent. I am not sure that its search for the distal end is stupid because it is unsuccessful. The search is zealous enough, but the axis cylinder shrinks from ignoble conduct with a baser tissue, and turns aside to seek elsewhere.

The lower severed end becomes thickly covered with a fibrous cap which forms a barrier impenetrable by the axis cylinders seeking so earnestly to find their way along the distal nerve.

1. THE NERVES INJURED; RELATIVE FREQUENCY.

The relative frequency of affected nerves has in our experience been as follows:

	Per cent.
Musculo-spiral	25
Ulnar	24
Median	14
Sciatic	12
External popliteal	12
Internal popliteal	1
Upper portion of the brachial plexus	4
Lower portion of the brachial plexus (cords)	7
Anterior crural	1

This corresponds fairly accurately to the experience recorded by Gosset and by Tinel.

2. DIAGNOSIS.

The following points in the clinical histories are investigated:

- Date of injury.
- Nature of projectile.
- Position of patient at moment of injury.
- Immediate effects.
- After-history (including history of operations performed).

Physical examination consists in—

A. Inspection of the limb, to note—

1. Attitude, contractures (claw hand, etc.).
2. Position of wounds and scars.

B. Testing of the efferent impulses.

1. Motor weakness for paralysis, each muscle and each muscle group tested separately.
2. Trophic and vasomotor disturbances. Non-shedding of epidermis, "glossy skin," ulcers, changes in nails, etc.
3. Changes in deep tissues, for example, muscular atrophy, fibrillation, bone decalcification, etc.

C. Testing of the Afferent Impulses.

1. Pain, its character, distribution, relation to hot and cold applications or weather.
2. Loss of cutaneous sensibility, tested by standardized stimuli of special instruments so that results are strictly comparable.
 - Light touch.
 - Localization of spot touched.
 - Tactile discrimination (pressure, texture, etc.).
 - Stereognostic sense (size and shape of three dimensions); appreciation of compass points applied simultaneously.
 - Thermal stimuli (hot and cold test tubes).
 - Painful stimuli (pinprick controlled by standardized spring).
 - Roughness (Graham Brown aesthesiometer).
3. Deep sensibility.
 - Pressure pain.
 - Vibration sense in bones.
 - Joint and muscle sense, etc.

D. Electro-diagnosis.

The reactions to the interrupted current are tested by shocks from an induction coil, the electrode being placed upon the "motor point" of each muscle in turn. The current from a secondary coil is always used.

* Delivered before the Congress of Surgeons of North America.

A positive reaction to faradism is regarded as a contra-indication to operation, but failure to respond gives no definite information, for voluntary movement may return, after nerve injury, before the faradic response.

The muscles are next investigated by a constant current. "Polar changes" have been found to be of minor value; they may vary with the local circulatory changes following massage, etc. The character of the contraction is of much more importance. A brisk twitch indicates the probable presence of some conducting nerve fibres in the muscle tested, while a slow "vermicular" response is usually associated with a complete interruption of nerve fibres.

The nerve muscle is next examined by means of a condenser discharge. The method depends upon the fact that a condenser discharge through a constant resistance gives a current which varies in duration according to the capacity of the condenser used.

The more severe the damage to the nerve the greater will be the capacity of the condenser required to excite it. Or, in other words, the longer the duration of the current the more chance is there of obtaining a response in such a nerve muscle. The whole advantage of the condenser method is that a definite measurement of current or condenser used may be noted, and future progress may be accurately followed.

The condenser method is chiefly used in cases where operation is deferred because some function is found to be present in a given injured nerve. (The work done recently by E. D. Adrian and others shows that the condenser is disappointing in practice; but it nevertheless gives useful information in recording progress.)

Complete absence both of faradic and galvanic response is an indication for early operation. The cases which require careful and repeated examinations are those where there is pressure on the nerve trunk by a contracting scar. In some nerve trunks there is little damage to some of the fibres, with total loss in others. Operation must not be deferred too long in these cases, because the fibres with complete reaction of degeneration may never recover on account of a dense scar tissue formation at the site of injury. In other words, the presence of a degree of voluntary power in some individual muscles of a group supplied by a damaged nerve is no sure criterion that the paralysed muscles will recover without operation.

It is most important that nerve injuries should be re-examined at frequent intervals and carefully detailed records of motor power, sensory changes, and electrical reactions kept. In this way treatment may be modified according to progress.

In operations upon nerves where a diagnosis of total loss in some fibres only has been made it is our practice to test the exposed nerve both above and below the site of injury at the time of operation.

For this examination special sterilizable electrodes and long connecting cords which can be boiled are used. The nerve is gently lifted upon two small glass hooks and a very weak faradic current employed.

The most accurate anatomical arrangement of fibres may be noted by this means and the knowledge used to secure perfect adaption in nerve suture. The diagnosis is often completed during a period in which massage, baths, and electrical treatment are employed to improve the local circulation, and splint treatment adopted to relax affected muscle groups and to overcome contractures. The distinction between anatomical and physiological division is not made before operation.

Difficulties in Diagnosis.

The main difficulties encountered in arriving at an exact diagnosis are in cases where there are:

- Wasting and stiffness from disuse.
- Circulatory disturbances.
- Contractures.
- Destruction or adhesion of muscle and tendon.

Operation is decided upon in the following circumstances:

1. In cases of complete division.
2. In cases of incomplete division, where progress is arrested.
3. Where there is severe neuralgic pain, "causalgia."

Operation is deferred—

1. For one month after the closure of the wound where soft parts only are injured.
2. For two or three months after complete closure of the wound where bone has been involved.
3. Definitely so long as progressive signs of recovery in nerve functions continue.

The suture of the nerve may have to be delayed until unsatisfactory joint conditions are improved.

Contractures of the knee, for example, should be corrected before the sciatic nerve is sutured, otherwise the nerve would be in danger of rupture if the deformity were subsequently rectified.

In other cases the nerve may be sutured and the joint dealt with at the same period and subsequently.

It is of the first importance to start active measures to prevent or remove stiffness and deformity in the parts supplied by a wounded nerve. This can often be done for many weeks before it is possible to repair the nerve. It is not sufficiently realized that a nerve to be of use after suture must act upon live and supple tissue. Joints and muscles must be kept ready for the nerve impulse which some day will come to them again.

Operations.

When the diagnosis of a nerve lesion requiring operation has been made, the earliest prudent occasion must be chosen for operation. In both the French and British armies nowadays the suture of a divided nerve is performed in those most advanced operating centres where the first deliberate toilet of the wound is possible. It is realized, of course, that very often a complete union between the severed ends cannot result, but even if the operation prove eventually to be a complete failure the subsequent operative procedures are certainly easier, and it is a satisfactory thought that a chance has been given for healing to take place.

In the great majority of nerve lesions dealt with up to recent times the wound inflicted by the projectile has suppurated. We have learnt by bitter experience in this war what this means. It means that the bacterial flora in such a wound are numerous, and potentially at least of great malignancy. It means that even a simple operation upon a wound which still discharges pus may arouse a flaming infection and be a cause of tetanus or gas gangrene. Mere passive movement of a joint grown stiff by inactivity may bring about an attack of tetanus even though the adjacent wound has healed. In many cases an injury to bone may have been inflicted at the same moment as the division of the nerve; this is, of course, frequently the case when the musculo-spiral nerve is implicated. Many loose pieces of bone may remain as sequestra in the wound and may need removal or may escape spontaneously from time to time. In all such cases operation upon the nerve must be deferred until the wound has been soundly healed for some weeks; no rule is more binding upon the surgeon than that. During this period, which may be protracted, the most diligent attention must be given to the limb, especially to those parts, muscles and joints, distal to the injury. The paralysed muscles must be kept in a position of relaxation. This may be easy, as in those cases where the musculo-spiral nerve is divided; it is often difficult, as in cases of injury to the median nerve; it is sometimes impossible, as in dual or triple lesions of nerve trunks. But, difficult or easy, the best possible must be done, for the final functional result in respect of quality and of rapidity depends in no small degree upon the early care of the parts deprived of their nerve supply.

Special and unremitting attention is given to the joints, which must always be kept supple. It is remarkable how quickly the fingers, for example, become so stiff that forced movement is an agony. Every day, many times a day, all the paralysed parts must be freely moved to their full range, and the patient must be instructed to attend to this matter unceasingly. The most perfect nerve healing is robbed of its value if, through long disuse, the muscles whose innervation is restored have lost their power to act, and if the joints are so firmly ankylosed that even passive movement cannot bend them fully. The value of these preliminary and preparatory measures cannot be over-estimated.

When the operation actually takes place it is important

to observe certain essentials to success. There must be the most perfect and scrupulous asepsis and the most gentle handling. The finger should never be placed in the wound. All dissection should be carried out deftly and neatly; the most diligent care must be taken never to bruise the nerve by seizing it, however gently, in forceps. The nerve must never be twisted, or torn or stretched, or unduly separated from its bed. Other structures must be dissected from the nerve; the nerve must not be dissected from them. The nerve must not be stripped bare for too long a distance, otherwise it will be devascularized, and recuperative processes will be slow or absent. The wound as a whole, and the nerve in particular, must not be allowed to dry or to be chilled. The most dainty and precise movements are necessary throughout, and every bleeding point must be thoroughly secured. There are, of course, the observances that go to make up the ritual of every well-trained surgeon; their strict acceptance is more necessary here than in almost any other operation, if the most rapid and the most flawless recovery is to be made certain.

As a rule a tourniquet is undesirable, for two reasons: It is possible to harm the nerve, or other nerves in the limb, if the rubber band is applied too tightly, and for the long period sometimes necessary in this procedure; and when the operation is complete and the tourniquet removed, there will probably be an escape of blood into the wound—a thing in these cases most undesirable. In these wounds not infrequently there is a good deal of young fibrous tissue, from which free oozing may occur in the period of hyperaemia which follows removal of a tourniquet.

The incision is designed to fall on the skin at some distance from the original wound if possible; very often a flap will occur from the making of a curved incision. The planning of the incision gives scope for one's knowledge of anatomy; it is so arranged that no small nerves are wounded. Major Jamieson has shown that when the median nerve is injured in the forearm it may sometimes be more thoroughly and successfully dealt with from the outer instead of from the inner side of the flexor carpi radialis. So, too, when the musculo-spiral nerve has been injured high up on the outer side of the forearm, Dr. Cutlbert Morton suggests that instead of cutting through the outer head of the triceps it should be reflected complete from the humerus. Not only does this cause less damage to the muscle tissue, but it also exposes the nerve and its branches, as well as the profunda artery, to a very high level without undue risk.

The nerve trunk is sought above and below the point of severance, and is traced downwards and upwards to the gap. Swift, neat little cuts with a very sharp scalpel damage the tissue to the smallest possible degree. The surgeon must avoid contact of his fingers with the wound; it is clumsy and inartistic to prod about among muscles in the hope of feeling the nerve. It is his business to know before he begins these operations exactly where the nerve lies, and he should always be able to cut directly down on it. When the injured part of the nerve is exposed, it is usual to find a bridge of fibrous tissue between the ends, the proximal end being often very turgid and bulbous. If the gap between the refreshed ends of the nerve is likely to be wide, now is the time for stretching the nerve, so as to lessen the interval as much as possible. This is done with infinite gentleness and care by seizing the fibrous band between the ends and drawing steadily upwards and downwards, always remembering to make the pull in the line of the nerve trunk and to avoid twisting. The fibrous band is now split longitudinally, and then its ends are divided above in one direction, below in the other, so that to each cut end of nerve a fibrous tag is attached, by means of which the nerve ends can be drawn together. Progressive transverse cuts are now made into the nerve ends until on the cross section nothing but nerve fibres are seen. Every tiniest particle of fibrous tissue must be removed or the operation will fail. The axis cylinders coming from above must have free entry into the nerve below, otherwise in their downward development they will lose their way, and restoration of the nerve function will not take place. When the nerve ends are duly prepared they are brought into apposition with the greatest care. A series of very fine catgut sutures holding only the nerve sheath are inserted at intervals round the circumference of the nerve. A suture is never

passed through the substance of the nerve itself. In uniting the nerve ends it is of the first importance to avoid axial rotation. We know now that there is a differentiation of function within each nerve, and it is therefore strictly necessary to unite corresponding bundles of fibres. A nerve does not act as a whole, but consists of a multitude of strands each with its proper and restricted function. Unless nerve bundles which were originally continuous are brought accurately together by suture, the nerve is compelled to rearrange the functions of its several parts. This it can and no doubt frequently has to do. An examination of many cases shows, however, that a perfect and flawless recovery after a nerve suture is unusual, and it is at least a tenable belief that this inadequacy or delay in recovery is due to a want of recognition by the surgeon of all that is needed in the technical part of the operation. My colleagues on the staff of the 2nd Northern General Hospital in Leeds are obtaining results which in rapidity and completeness would have been thought impossible before the war.

There is rarely any difficulty in obtaining accuracy of apposition without tension. If, however, the nerve ends cannot readily be brought together, various procedures may be adopted to shorten the course of the nerve. The nerve may be dislocated from its bed and laid in a new and shorter line. The ulnar nerve, for example, may be brought to the front of the inner condyle. Or flexion of the limb may be enough to allow of easy approximation. In the case of the median nerve divided low in the forearm, flexion of the wrist will give an inch or more additional reach. In other cases the limb may be shortened by removing an inch or two of bone. It is desirable to avoid a subcutaneous course in all transferences to new positions. The nerve after suture should be brought to lie in a bed of healthy tissue. It must be placed between muscles, and away from all contact with new connective tissue, which will adhere to it, and hinder its union, or cripple its subsequent action.

It has been the fashion with many surgeons to surround the sutured nerve with some material supposed to have protective virtues. A piece of a vein—the saphenous, for example—is threaded over the upper cut end of the nerve before suture, and after these ends are approximated the vein is drawn downwards and made to surround the line of suture. In other cases a piece of fat dissected from near the wound, or from another part, is wrapped round the nerve, fat being supposed to be capable of insulating the nerve in its new position, or a layer of fascia may be used, or a piece of Cargile membrane. The value of all such methods is open to serious question; it is certain that they are sometimes harmful, it is doubtful if they ever help. They prevent access of blood to the nerve by new channels; they cause adhesions and compression of the nerve, and at times they are discharged from the wound almost unaltered. It is better to avoid such membranes, and to be content with ensuring that the nerve is laid along a path of uninjured tissues. Where end-to-end suture is impossible, a variety of other procedures may be attempted. A nerve graft, taken from a neighbouring cutaneous nerve, from the radial, the internal cutaneous of the thigh, or an intercostal nerve, may be used. Experience on the human subject has not yet enabled me to determine the value of this procedure. In experimental work it answers well, but I have rarely, if ever, seen a result which could be claimed as satisfactory. Colonel Mayo-Robson has had one of the very few successful cases.¹ Nerve anastomosis has been tried in a number of cases. The divided ends of a nerve are implanted into the side of a near-lying nerve, the ulnar into the median, for example. This has been done both with and without section of the nerve fibres of the intact nerve. All such procedures are worthless, and cannot be too strongly condemned. I have never seen any good come of them; indeed nothing but harm could conceivably result from section of a healthy nerve. And if it is allowed, as it must be, that a nerve consists of many separate strands, each with its own special and exclusive function, it is certain that permanent damage is inflicted by this method. There is no justification for this procedure nowadays, and it should be cast out among forgotten things. Lengthening of the nerve by turning down a strand from the upper divided end, or the bridging of the gap by strands of catgut, are methods with nothing whatever to recommend and everything to discredit them.

Happily the resources of surgery are not at an end in all cases where union of divided nerves is impossible. Tendon transplantation, especially in the case of the musculo-spiral nerve, and the posterior interosseous, gives results which in point of function are almost as good as those which come from nerve suture, and in point of time are much quicker. It is chiefly in the musculo-spiral nerve that large gaps are found, a piece of the nerve having been blown completely away. In such cases tendon transplantation gives excellent and speedy results. When the posterior interosseous nerve is wounded it is not worth while attempting to suture the nerve. The results in such cases are slow, and not always perfect.

In those cases where the nerve is partly divided, strands of intact fibres still remaining, the severed fibres are united in the same careful way, and the normal strand of the nerve bent upon itself, so as to allow easy approximation of the cut portions of the nerve. In perhaps the majority of operations upon nerves there is no division of fibres, but a length of the nerve is embedded in dense fibrous tissue. These cases give most excellent results. The fibrous tissue which so intimately surrounds the nerve is dissected away little by little. The nerve when first freed is seen to be white and shrunken; but within a few minutes it expands and takes on its normal colour. I had several cases of this kind in the Boer war, and the results at this long interval are perfect. It is in these cases that advantage may sometimes be taken of the method of fat transplantation, or of nerve dislocation.

AFTER-TREATMENT.

1. Postural.

In cases where flexion of a joint has been necessary to allow approximation of the cut ends of nerves, the position is maintained for a period of six weeks. By this time union of the severed ends is probably well advanced. Extension by slow and most cautious degrees is then begun. If the knee has been flexed to allow the sciatic nerve to be united the patient can walk with a boot and leg irons, keeping the position unaltered for, say, two months. Wherever possible a splint is applied which produces a "relaxation position." In the case of the median and ulnar this is difficult, and is best secured by moulding a "ball splint" to the hand of the patient. Every such splint must be made for the individual. In the case of the musculo-spiral it is very simple. The "cock-up" splint designed by Colonel Sir Robert Jones is excellent, if the lesion of the nerve is below the branch to the supinators. It maintains hyperextension of the wrist, and, reaching only to the heads of the metacarpal bone, it allows a forward bend of the metacarpo-phalangeal articulations. The thumb lies forward and a little inwards, so that the position of the whole hand is very much that assumed when a bottle is grasped. If the lesion is above the nerve to the supinator brevis, it is essential that this muscle also should be relaxed. For this purpose Dr. Cuthbert Morton has devised a splint which retains the forearm and hand in supination while the wrist is fully extended, the fingers being at the same time kept in the bottle-grasping position.

Similarly, in cases of injury to the external popliteal nerve, relaxation of the corresponding muscles may be secured by the boot which has been introduced by Dr. Cuthbert Morton in order to allow the patient to walk about with the foot in permanent dorsiflexion.

2. Massage and Electrical Treatment.

These measures are restarted about two weeks after operation with all due precautions and safeguards. If a splint has been applied to secure the "relaxation position," it must not be removed. Indeed, not for one moment at any time must paralysed muscles be stretched. An overstretching of a few minutes may call for diligent treatment of many weeks before the harm is undone. If a splint needs removal for purposes of cleanliness, the patient must be instructed beforehand to keep the limb in the exact position required. In the case of musculo-spiral palsies the hand drops into the correct position if the flexor surface of the forearm is *upward*.

RESULTS.

Our records are as yet necessarily incomplete. Recovery in the case of the musculo-spiral has begun within nine

weeks; in the case of the ulnar within three and a half months; in the case of the median in about four to five months. In one case of division of the inner cord of the brachial plexus recovery in all anaesthetic areas and a degree of recovery in all muscles occurred within five months. Recovery in the case of the sciatic nerve is slower. Something depends, it is sometimes said, upon the length of time elapsing between division of the nerve and its suture. My colleague, Captain Richardson, has, however, united the ends of an ulnar nerve cut across fifteen years before and signs of returning function were seen in about four months. The duration of the disability is, therefore, no bar to successful repair of the nerve.

The functions return usually in the following order:

1. Trophic and vasomotor function.
2. Deep sensibility.
3. Tactile discrimination and localization.
4. Motor power.
5. Cotton-wool sensation.

Perfect restoration of function has been most nearly approached in the case of the musculo-spiral nerve. In other nerves with more complex distribution perfect recovery will depend upon a recognition of the functional localization within the nerve trunk, in addition to the most scrupulous observance of all those technical details without which there will always be something less than perfection.

In the diagnosis and treatment of an organic lesion of a nerve it should never be forgotten that there may be superadded a functional disability. It is advisable at every stage to get rid of the functional in order properly to appreciate the organic. This is particularly important when the organic lesion is well on the way to recovery. Thus, in a recovering lesion of the inner cord of the brachial plexus it may be impossible for the fingers to be flexed until re-education has trained the laggard muscles into obeying orders from head quarters.

SUMMARY.

The following summary may be given of our experience up to the present time:

1. The earliest examination should be made of all wounds in which division of a nerve trunk is probable. If at the casualty clearing station such a lesion is found, end-to-end suture should be adopted forthwith. This is more likely to be possible in cases where primary suture of the wound, after excision, is found practicable.
2. If secondary sutures of the wounds, after the Carrel-Dakin method has been practised, is to be undertaken, the union of divided nerves should be secured at the same time.
3. If these methods have been attempted and have failed, they do not prejudice the later union of the nerve. On the contrary, they probably ensure that an easier and more satisfactory operation can then be practised.
4. Throughout the whole period before late nerve suture is attempted the strictest attention must be paid to the relaxation and nutrition of all paralysed muscles, to the maintenance of suppleness in all joints moved by these muscles, and to the preservation of the integrity of the skin.
5. Operations upon nerve trunks demand the most scrupulous observance of the ritual of asepsis. There must be the greatest gentleness of manipulation; the nerve must not be injured by instruments or by the surgeon's finger; it must not be separated from its sheath or disturbed overmuch from its bed; it must not be chilled or allowed to dry. All sutures must be of fine catgut, and introduced with most punctilious accuracy. Axial rotation of the nerve must be avoided. The cut ends of the nerve before approximation must show clearly the fibres of which the trunk consists.
6. Nerve-grafting is of little or no value; nerve anastomosis is to be sharply condemned; the turning down of flaps from the nerve to bridge a wide gap is useless.
7. Tendon transplantation is of great value in cases where nerve suture is impossible, or has given a result not entirely satisfactory.

SURGICAL TREATMENT OF GUNSHOT WOUNDS OF THE CHEST.

THE SURGICAL TREATMENT OF SEVERE PENETRATING WOUNDS OF THE CHEST IN A CASUALTY CLEARING STATION.

By J. ANDERSON, CAPTAIN R.A.M.C.

It is generally accepted that the sooner a wound is purged of carrying agents of infection—namely, foreign body and clothing—and of the media suitable for the growth of bacteria—namely, blood clot and dead muscle—the better is the prognosis.

Reflection on the experience of two years of casualty clearing station work reveals the fact that in no group of cases has this axiom been so much neglected as in wounds of the chest. It brings home the very dangerous nature of many of these wounds, and makes one wonder why serious attempts have not been made long ere now to apply to them principles which have led to such marked improvement in the treatment of wounds of other parts. These serious cases have arrived in large numbers at casualty clearing stations, have improved up to a point, and then have succumbed to sepsis; just as in other wounds which have been inefficiently treated.

Wounds of the chest, as seen at an advanced casualty clearing station, may be classified into two main groups from the point of view of prognosis.

Group A.

1. Entrance and exit bullet wounds.
2. Entrance and exit shrapnel-ball wounds.
3. Wounds caused by small fragments of high explosive missiles.

As a general rule these cases do exceedingly well if treated expectantly and aspirated or operated on when occasion demands. They can usually be evacuated to the base in from three to ten days, and the ultimate results are good. Of course, in a certain proportion of such cases there is sufficient visceral injury to cause immediate or early death, but, as they seldom reach the casualty clearing station, they do not come within the scope of this paper.

Group B.

1. Wounds caused by large irregular fragments of high explosive shell which have lodged in the thorax. These are almost always associated with (a) clothing and infection carried in, and (b) open "sucking" wounds of the chest wall.
2. Tangential wounds of the thorax, enfiling the ribs and driving portions of bone, etc., into the pleura and lung.
3. Entrance and exit bullet wounds in which the exit wounds are "explosive" in character.

If treated expectantly only a very small percentage of Group B (1) reach the base, and many of those that are evacuated appear to die from the complications of their wounds.

In Group B (2) and (3) the prognosis is usually not so severe, but an unduly large percentage develop an infected haemothorax unless the chest wall wound is treated energetically. In this latter group the prognosis, when no operation is performed, is always worse in wounds of parts where there is a liberal muscle covering—for example, in the scapular region.

The cases in Group B usually have died hitherto at the casualty clearing station from sepsis and exhaustion, and it is this group of cases which demands more vigorous surgical intervention.

The mortality in all penetrating wounds of the chest at a casualty clearing station appears to vary from 7 to 25 per cent. or over. It is higher in stationary trench warfare, and in casualty clearing stations which are placed near the "line"; that is, there are more of the B group of cases. The question that faces us is: Cannot many of these cases which otherwise succumb be saved by immediate surgical intervention on the lines adopted for other wounds? Recent experience of this type of work has assured me that this is possible. The main factors which have militated against active interference on the part of

the surgeon are: (1) The danger of anaesthesia, (2) lack of experience in chest surgery, and (3) the fact that the surgery of the chest in civil practice has always been associated with very elaborate paraphernalia. One finds, however, that these objections are "phantom," or can be overcome.

As to (1), the majority of these cases can be efficiently anaesthetized by the regional method of local anaesthesia—namely, blocking the intercostal nerves in the intercostal spaces behind the angle of the rib with novocain solution 0.5 per cent. Where general anaesthesia is rendered necessary on account of multiple wounds, or because of restlessness of the patient, anaesthetists who have had experience of this type of case agree that the immediate danger is greatly overestimated, and that the closure of an aperture in the wall of the thorax more than compensates for any risk which is accepted. One must not forget the possible effect of a general anaesthetic on the "sound" lung already overstrained. (2) The operation does not demand manipulative skill beyond that possessed by a good general surgeon; and (3) it can be performed with the ordinary surgical kit of a casualty clearing station.

Principles of Operation.

A localizing x-ray examination is of extreme value. The extent of damage and route of attack can thus be much more accurately gauged and the operative procedure simplified. If, however, for any reason x rays are not available, I am satisfied that much is gained by the excision of the wound in the chest wall and closure thereof, with modified search for the foreign body. In several cases I have removed the foreign body successfully at a later date, when the patient's condition had improved. The wound in the chest wall should be completely excised, all loose and sharp fragments of rib being removed. The pleural cavity should then be wiped out, if the lung has collapsed and haemothorax exists. A search for the foreign body should now be made, the wound being enlarged if necessary to admit the hand. This may not be required, however, if the lung is adherent. It may be possible to palpate and control the affected part of the lung with two fingers, especially if the foreign body is lodged in the lower border. The fragment, with any carried-in clothing, is now removed, the lung being grasped by the hand or fingers. In some cases the affected part of the lung may be completely excised. The wound of the lung is treated by suture, plugging, smearing with an antiseptic paste, etc., according to indication, just as in wounds of other parts. Often the greater part of the damage has been done by portions of rib driven in, and these frequently cause several separate wounds of the lung.

Whether antiseptics should be used in the pleural cavity or not is still a moot point. I have used solutions of flavine and brilliant green without any untoward effects and probably with advantage.

The aperture in the chest wall is closed by catgut suture. Suture of overlying muscle may be used for this if the pleura is deficient, but the latter can usually be approximated. Suture of the muscle layer completes the closure of any minor deficiencies. The skin wound is closed by sutures at wide intervals, a dressing is applied and fixed by adhesive plaster. The great matter is to get the chest completely closed.

The marked improvement in a patient's condition during an abdominal operation on closure of the diaphragmatic wound was expounded by Captain Lockwood, and has been accepted by all. The same astonishing mechanical phenomenon appears after closure of open wounds of the chest.

If the operation is performed under local anaesthesia the patient can be got to expel a part or the whole of the air in his pleural cavity as the last suture is being tightened.

The whole aim of the operation is prophylactic against sepsis, and to bring the patient as nearly as possible to the *status quo ante*. If it fails, a secondary drainage operation may be required later. The procedure helps to eliminate secondary infection from the outside.

The lung expands gradually and apparently in inverse ratio to the amount of visceral damage. I have seen several cases in which a pneumonic condition appeared on the healthy side, and where the patient was apparently tided over the crisis by the activity of the wounded lung.

While operating on cases of infected haemothorax with open "sucking" wounds or severe rib injury, I have on several occasions found the lung adherent to the chest wall in the neighbourhood of the wound. The haemothorax is shut in by these adhesions. I have seen the same at two autopsies. Is this an attempt by nature to close an open chest cavity? It would explain the anomalies in clinical signs found in some cases and might account for the occasional difficulty in getting a sample of pleural fluid when an infected haemothorax is present. In two cases I have seen recent adhesions of the sound lung to the chest wall. I think this may be more common than is generally accepted.

Of course, one is dealing with a class of case in which the injury is very severe and the operative mortality must be high. When one considers that the large majority of cases will die if "left alone" the results indicate a very considerable advance on the more conservative methods of treatment.

Cases in Group B (2) and (3) do almost uniformly well if treated on these lines. Those earlier cases which died appeared to succumb to a secondary infection of the pleural cavity from the infected wound of the chest wall.

In the majority of the simpler cases of septic haemothorax which died in the casualty clearing station to which I am attached a streptococcus appeared to be the main infection. It is probable that systematic very early exploratory aspiration and culture will indicate means whereby this mortality may be reduced. It appears to me that this branch of surgery, although still in its infancy, has already saved many lives which would otherwise have been lost. Results will improve with improved technique and further investigation.

These are the factors which incite me to put in print my early findings. From my point of view, these remarks are premature, but, if I succeed in attracting attention to what has been a somewhat stagnant field of surgery, this article will have served its purpose.

In a working period of approximately two months the following results were obtained:

Total cases of Group B operated on and chest	
wall closed	58
Evacuated apparently doing well	44
Died	14
Required secondary operation (drainage, etc.)	12
Number of cases with multiple wounds	29

Attached are the short original unaltered notes of the last six consecutive cases included in the above statistics.

CASE I.

Pte. A., wounded 1 a.m. June 16th, 1917. Large shell wound through left arm. Fragment proceeds through latissimus dorsi into left chest—open sucking wound. Haemothorax; surgical emphysema. Patient getting progressively worse since admission. Symptoms: dyspnoea, with sense of suffocation; cyanosis. Pulse 140.

June 16th, 3 p.m. Under morphine, local novocain, chest wall wound excised with four inches of sixth rib. Large wound of lung felt, but owing to patient's very precarious condition no extensive search for foreign body was made. One ounce of 1 in 1,000 brilliant green was put in chest after swabbing out. Closure of pleura. The patient began to improve immediately. Chloroform administered for rough trimming of arm. Pulse after operation 120.

The patient gradually improved, but on June 22nd still had a temperature of 102° and pulse 96. Chest aspirated; bacteriological examination negative. Only ½ oz. fluid obtained. No trace of brilliant green. Right lung showed signs of basal congestion, which Colonel Herringham considered was probably pneumonia.

On June 26th temperature 102° and pulse 108. Dull patch at base of left lung behind. Under local novocain, portion of ninth rib resected over dull area and localized abscess evacuated with large foreign body, wedged in body of tenth dorsal vertebra. This cavity communicated with a bronchus, but was shut off from pleural cavity. Carrel-Dakin. Progress steady. Patient evacuated in excellent condition, with normal temperature and pulse, on July 7th, 1917.

Note.—Here the affected lung carried the patient through his pneumonic crisis. Simple closure immediately improved the patient's condition.

CASE II.

Prisoner of war, H. S., wounded June 15th, 1917. Entrance and exit shell wound, right chest. Operation June 18th, 1917, under local anaesthesia with omuopon. Large posterior sucking wound excised. Thorax wiped out. Lung found adherent to exit wound, partially blocking it. Streptococcal haemothorax. Symptoms of suffocation. Chest wall closed.

Improvement for twelve hours; death after twenty-four hours from streptococcal septicæmia. Extensive wound in lower lobe of right lung.

Note.—Streptococcal infections are always severe. Sucking wounds which are closed late have always a more serious prognosis.

CASE III.

Pte. B., high explosive wound, chest and left leg, June 16th, 1917. Entrance and exit wound, right scapular region with large open wound in neck; fracture of first rib behind angle. Extremely collapsed. Breathing very distressed. Under chloroform, partial excision of track. Bipp, paraffin pack, entirely plugging opening in neck. Severe bronchitis of "sound" lung.

June 22nd. Aspirated, 20 oz. Negative bacteriological report.

June 26th. Temperature and pulse normal.

July 3rd. Evacuated, well.

Note.—When the track cannot be efficiently excised and closed a paraffin pack (gauze wrung out of liquid paraffin) is extremely efficient.

CASE IV.

Pte. J., wounded June 21st, 1917. Under chloroform and oxygen, wound of left lower chest with tear of tip of lower lobe of lung and diaphragm. Foreign body removed from diaphragm, which was sutured with catgut. Upper wound small; excised. Fragments of rib removed from entrance and exit wound of lung; 40 c.cm. brilliant green injected (into pleural cavity), chest wall closed. Multiple wounds of left arm; partial excision and Carrel.

July 2nd. Temperature normal but breathing easily disturbed by moving.

July 4th. Evacuated, apparently well.

CASE V.

Pte. P., wounded 12 midnight, July 2nd, 1917. Operated on twelve hours later. Much shock; hypertonic intravenous saline. Resection of fractured ribs in front. Hernia of omentum into chest cavity. Excision of wounds. Hernia reduced. Diaphragm closed by six sutures; chest wall closed by suture. After wiping out haemothorax and 1 oz. brilliant green injected, bullet casing removed from spleen. Spleen and kidney drained, packed with gauze; only upper pole of kidney damaged.

July 12th. This patient has made practically an uninterrupted recovery.

CASE VI.

Second Lieutenant X., wounded June 30th, 1917. Wound of kidney, spleen, and large tear of diaphragm from chest wall. Haemothorax wiped out; brilliant green injected, and diaphragm stitched to chest wall with mattress sutures. Fragment of shell removed from above spleen. Upper pole of right kidney pulped; spleen and kidney packed; no apparent injury to lung. Uninterrupted progress.

July 8th. Patient evacuated, well.

THE SURGICAL TREATMENT OF SEVERE WAR WOUNDS OF THE CHEST.

BY

CAPTAIN J. E. H. ROBERTS, R.A.M.C.,

AND

CAPTAIN J. G. CRAIG, R.A.M.C.

THE early treatment of penetrating wounds of the chest is one of the problems of the present war which is of the greatest importance.

Up to now the materials for the discussion of the problem have been relegated mainly to the physician, and it is only recently that the surgeon has had the opportunity of operating on any but late cases. Accordingly the results of a sufficient number of cases on which to form a just estimate of the value of operative treatment as compared with expectant measures have not been available.

We have collected the results of our experiences of these cases, and we offer them as a contribution to the discussion.

During the earlier part of the period the results have led us to believe that, except in cases where the general condition of the patient will not allow of these measures, there is no defensible reason why chest injuries should not be treated at the earliest moment on exactly the same principles as wounds of other parts. It is generally admitted that the proper treatment for open wounds of limbs is to excise all the lacerated tissues and to remove the foreign body. In so far as these measures are not carried out with perfect technique and success, so

much longer is the patient in becoming fit for service again.

Sepsis may be carried into the depths of penetrating chest wounds and develop there primarily, or it may pass gradually from the skin through lacerated muscle, smashed rib, and torn pleura, and ultimately fulminate in the pleural cavity or wounded lung. This latter type of what might be termed secondary infection is seen especially in cases of perforating bullet wounds with explosive exit.

It must be remembered that the pleural cavity, when filled with effusion and blood clot, is, in a general way, one of the finest incubating chambers an organism could have. Even in the case of perforating bullet injuries with insignificant entrance and exit wounds one must always be on the look-out for evidence of a septic infection of the usually concomitant pleural effusion.

The principles we have tried to follow in the treatment of chest wounds recently dealt with have been identical with those guiding the operative treatment of a wound of a joint. In these latter cases the two essential rules are:

1. Complete removal of all possible sources of sepsis.
2. Conservation of the function of the joint if this is compatible with (1).

As applied to penetrating chest wounds these principles involve operation at the earliest possible moment, free excision of all infected tissues, removal of the foreign body and cleansing of the pleural cavity or wound of the lung, followed by accurate suture of the lining membrane and tissues over it, whenever possible without drainage. Drainage of the pleural cavity has been employed only when one or other of these principles could not be fulfilled—for example, when a large foreign body, with infection around it, could not be removed.

When anaërobic infection of the superficial muscles is present the wound is left open to an extent corresponding to the area of the infection—for example, in the case of a wound of the back when the more superficial muscles alone are infected it is possible to suture the pleura and leave the superficial part of the wound freely drained.

There does not seem to be grave objection to washing out with, and possibly leaving inside the pleura, a few ounces of a non-irritating antiseptic, such as Dakin's or flavine solution, but the necessity for this is by no means established.

The 199 cases of perforating wounds of the chest dealt with by us can be divided up into four classes as follows:

	Cases.
1. "Open" or sucking wounds with free air entry	39
2. "Closed" wounds with large septic laceration of the parietes	32
3. "Closed" wounds with early signs of infection of haemothorax	20
4. "Closed" wounds with no evidence of intra-pleural infection	108
Total	199

All cases in Class 4 were evacuated to the base as soon as they were fit to travel, without operative interference of any sort.

It is a fallacy to regard many of the cases in the last three classes as closed with regard to access of infection to the chest cavity, and it must be understood that the term "closed" is applied to these wounds purely in the macroscopic sense.

The cases for operation were not chosen. Many apparently hopeless cases were undertaken, and we were rewarded by the recovery of many whose condition before operation had been despaired of.

In the first three days of the period under review there were no fewer than twenty-two deaths in cases in which no operation had been performed and in which the chest wound was the principal injury. This will give some idea of the gravity of the wounds and of the condition in which the patients arrived at the casualty clearing stations. This high mortality impressed upon us the necessity of adopting surgical measures more frequently and earlier. Partly on account of the number of other cases hitherto regarded as deserving more urgent surgical attention, our chest cases were seldom operated upon until they had been in hospital for one to three days.

Only such cases as, in the light of the mortality of the

first three days, were in all probability going to die if left alone were taken to the operating theatre.

General Condition of Patient.

Respiratory distress was practically always pronounced, and in some cases it was intense. In many cases mental anxiety was a noticeable feature. The usual signs of loss of blood were present in greater or less degree.

After a few days, especially in septic cases, the skin assumed a lemon-yellow tint, and in some instances the patient became quite jaundiced in appearance although the liver was unwounded.

The temperature we found to be of varying ranges, but in the majority of cases it was normal or subnormal on admission. Respiration and pulse rate were invariably quickened and breathing was laboured and attended with pain. Haemoptysis was a constant symptom when the foreign body had penetrated the lung tissues, but it never assumed alarming proportions.

Physical Signs.

The physical signs presented a striking uniformity. The side on which the wound was situated did not move freely; vocal fremitus was feeble if present at all; on auscultation no breath sounds could be heard at the base of the affected side, but in the upper part of the chest bronchial breathing, with crepitations or râles, were very frequently present. Vocal resonance was absent over the lower part of the chest, and between that area and an area of normal resonance or hyper-resonance in the region of the apex of the lung there was very frequently an area where oegophony was present. Over the base and back of the chest on the wounded side there was usually an area of total dullness, indicating the extent of the effusion. Curiously, no cases were found in which the effusion was hidden by the presence of adherent lung, as has been experienced by other surgeons.

In open cases a pack of gauze was usually found *in situ* on admission. On removal of this, as a general rule, fluid of varying nature bubbled out from the wound with each upward movement of the diaphragm. Removal of the plug invariably increased the distress of the patient, which again was relieved soon after the opening was re-occluded. This observation had great influence in deciding the operative treatment. The immediate improvement in respiratory comfort when the pleural cavity was closed at operation was very striking.

Preliminary Treatment.

Most of these cases arrived from the various dressing stations in a condition of respiratory distress, and many were suffering from collapse.

They were put in a special ward, warmed up by various measures, and allowed to rest quietly. If the patient was very distressed 1 c.cm. (one-third of a grain) omnopon (Roche) was administered hypodermically. One pint of hot coffee with 1 oz. of glucose was given by the rectum. If necessary, 15 minims of a solution of camphor 1 part, olive oil 4 parts, and ether 5 parts were also given intramuscularly. These wounds produce more mental anxiety than do wounds of almost any other part, and by blunting the patient's sensibility we found that the mental distress disappeared, and the general condition gradually improved.

The patients were found usually to be most comfortable when well propped up in bed in Fowler's position; if they slipped down they soon began to show symptoms of distress, which passed off when they were lifted up again into their former position. Tight clothing and bandaging were avoided. The risks of septic bronchopneumonia of the uninjured lung are great, and to attempt to combat these, creosote (2 minims in mucilage) was given three times daily. In cases where there was little or no expectoration but where moist sounds were numerous, a mixture containing ammonium carbonate, tincture of digitalis, and tincture of senegae was also given.

Examination of fluid from the pleural sac was carried out in many cases, and in the large majority streptococci were found. In order to try to diminish the virulence of this infection, polyvalent antistreptococcal serum, 10 c.cm., was given as a routine to the most severe cases of chest wounds after we realized the prevalence of this form of infection.

In many cases nothing further in the way of treatment was necessary.

Indications for Operation.

Open cases were operated upon as soon as the condition of the patient permitted. The great majority of cases in this class have never hitherto reached the base.

"Closed" cases with gaping or lacerated wounds of the soft parts and bone, whether scapula or clavicle, were treated as soon as possible.

As regards the remaining cases the indications for operation were based on (a) the general condition of the patient, and (b) the physical signs.

So-called "closed" cases without large wounds of the soft parts were usually left alone; a little bismuth, iodoform, and paraffin paste was rubbed into the wound and the skin disinfected round about.

If the respiratory distress increased, especially when accompanied by increasing displacement of the heart, operation was performed. In many cases, even when a preliminary exploratory puncture had been made, the result of bacteriological examination was not waited for, as experience showed that sometimes the withdrawn fluid produced no growth, while that obtained at the operation was proved to be infected.

Nature of Operation.

Where the external wounds were large, through-and-through, and the foreign body had traversed the lung and pleural sac, one or both, the wounds were excised, including the smashed ribs and soiled edges of the pleura. If possible this was done *en masse*. In bullet wounds it was usually unnecessary to excise the entrance wound.

If the site of the wound permitted of free inspection of, and access to, the pleural cavity, sufficient rib was removed to allow of insertion of the hand into the pleural sac for exploration and cleansing.

If sufficient access could not be obtained, owing to the position of the wound, four inches of the eighth or ninth rib below the axilla were removed and the pleural cavity was freely opened. This usually was enough to allow of inspection, palpation, and cleansing, but if more access still was required the rib above was divided or resected.

The procedure detailed in this last paragraph was also carried out in cases subjected to operation when only small "entrance and exit" wounds existed.

Injuries to the Lung.

If the wound of the lung was a superficial tear it was palpated and freed, by wiping, from blood clot and possible foreign material; if it bled it was sutured by a rounded needle and catgut or rubbed with bismuth, iodoform, and paraffin paste, and packed with gauze.

A through-and-through wound of the lung was usually left alone, unless very large.

Gangrenous portions of lung were clipped away, bleeding being stopped as above described, but haemorrhage was seldom found to be a troublesome factor. All blood clot was carefully removed from the pleura and the cavity was left as dry as possible.

When the Lung is Adherent.

In cases in which there is a localized inflammatory area in the lung and it is adherent to the parietes we consider that early operation is especially important because of the danger of the spreading of inflammation in the uncollapsed lung. Free access in such cases is easily obtained by excision of the superficial soft tissues and ribs, and the finger can then be introduced in order to ascertain the direction and extent of the track. Before this examination it may be necessary to fix the lung to the parietal pleura by stitches to prevent recent adhesions being broken down.

If the foreign body and clothing are felt they can be removed with forceps. If the haemorrhage prove troublesome the wound can be packed with dry sterile gauze lightly smeared with bipp paste, and in any case the "bed" of the foreign body should be carefully wiped out, smeared with paste, and a drainage tube or light gauze pack inserted.

When the Lung is not Adherent.

We found that the lung was non-adherent in the majority of instances, and this factor makes treatment much

more difficult. The operative measures we adopted were as follows:

The foreign body was sought for and removed. If it was embedded in the opposite wall of the thorax or mediastinum the aperture of exit could be seen or felt, and, if necessary, a separate incision was made for its removal. An attempt was always made to excise the margins of the exit wound in the pleura and to stitch them together. If this cannot be done the track should be rubbed with bipp from the pleural side. In some cases the foreign body was found at the base of the chest, having gravitated there.

If embedded in the lung, that organ was pulled up and fixed between the fingers, or caught with forceps, and the foreign body was removed as already described. When discovered near one of the margins of the lung, it was found to be an easy matter to excise the lung tissue enclosing the foreign body, and to suture the cut surfaces.

The pleural cavity was then wiped clean of blood clot very carefully and the pleura stitched up. Suture of the pleura proved usually the most difficult part of the operation. In order to facilitate it, subperiosteal resection of a considerable length of rib was performed when necessary.

Catgut threaded on a curved intestinal needle was used as a continuous suture to bring the divided edges of pleura accurately together when the suture was pulled tight. The patient was then roused if necessary, and asked to make a forced expiratory effort with closed lips while holding his nose. The object of this was to produce expansion of the collapsed lung and thus to expel air from the pleural sac. When this had been satisfactorily accomplished the catgut suture was tightened and tied.

In all cases not too widely infected the muscles were stitched up layer by layer. The skin was sutured, and the wound was then closed and no dead spaces were left.

In some cases a small drainage tube was put in almost down to, but not actually in contact with, the pleura, so that there was no danger of its producing a communication with the cavity. If, however, excision had been thoroughly done, and the wound had been irrigated with antiseptics (Dakin's or flavine solution) and rubbed lightly with bipp, it was found unnecessary to use drainage of this kind.

If the edges of the pleura would not come together the muscles and the skin were stitched over. As smooth a muscular surface as possible should be presented to the expanding lung. If neither pleura nor muscle could be brought together, the skin, at any rate, was always sutured. A plastic operation was performed if necessary to permit of this.

Drainage of Pleural Cavity.

No cases were drained unless (1) the chest wall could not be closed owing to the condition of the patient; or (2) if infection of the lung, or of the pleura as distinguished from its contents, was definitely established.

We soon overcame our scruples about completely closing up cases with a streptococcal infection, but we must admit to a more gradual conversion to the idea of closing cases with anaerobic infection. This, however, we have proved to be quite a safe procedure when the precautions we have enumerated are carried out.

In cases in which drainage had to be resorted to—for example, when suppuration was definitely established—the cavity was drained by means of a large tube, half an inch in diameter, with one end reaching just inside the opening in the pleura, and retained in position by one or more stitches. The tube was long enough to reach under the surface of a solution of boric acid in a wide-mouthed glass bottle which stood upon the floor at the side of the patient's bed. The use of such a receptacle and long drainage tube is not only a means of causing a negative pressure in the pleural cavity and of saving expense in the matter of dressings, but the patient was thereby rendered much more comfortable, as he was saved from having to lie in soaked and offensively smelling dressings. When the discharge becomes less in amount it is advisable to cut this tube off one to two inches from the skin surface and to wash out the pleural cavity two or three times daily with Dakin's solution or flavine. To do this it is advisable to pass a smaller piece of rubber tubing—for example, a catheter—through the stitched tube; this ensures a free return of the injected fluid. The patient can help in the

washing out process and the expulsion of the fluid by coughing. When the cavity is not being washed out the wound is covered with an antiseptic dressing, and external to this is a piece of jaconet larger than the dressing. This latter has a valvular effect and prevents the sucking of air into the pleural cavity. The piece of jaconet or rubber tissue may be placed directly on the skin in some cases, no tube being used. By its valvular action the occluding covering favours expansion of the lung.

Anaesthetics.

In the choice of anaesthetics the tendency to inflammation of the hitherto unaffected lung and the frequently irritating property of general anaesthetics must be remembered.

Local anaesthesia has not only the advantage of avoiding this irritation, but of enabling the patient to expand his own lung before final suture, and thus special pressure apparatus is rendered unnecessary. But the surgeon who attempts to operate on chest wounds under nerve blocking and local infiltration purely and simply will meet at first with disappointing results. In this, as in other procedures, practice makes perfect.

The patient must be rendered drowsy first of all if the full benefits of local anaesthesia are to be reaped. For this reason we gave the patient 1 c.cm. of omopon and scopolamine ($\frac{2}{3}$ grain omopon and $\frac{1}{15}$ grain scopolamine) one hour before operation, and if he was not drowsy in half an hour another one-third grain omopon alone was given. The local anaesthetic used was novocain 1 per cent. with 10 minims of adrenalin hydrochloride added to every ounce used. The average amount of solution required was three to six ounces.

In addition to local infiltration around the wound, blocking of the intercostal nerves, at or just internal to the angles of the ribs, was carried out. It is essential to block at least one nerve above and below as well as those involved in the wound. In wounds of the upper part of the chest the descending cervical nerves must be blocked. If the scapula is involved, as is fairly frequently the case, the suprascapular twigs may be anaesthetized by injection of the dorsal scapular muscles all around the injured area.

RESULTS.

Of the 199 cases, 103 were evacuated without operation, 24 died without operation, and 67 were operated on.

Of these 67 apparently forlorn hopes, 34 eventually recovered and were evacuated to the base, and 33 died. Of the 33 fatal cases, 16 had other gross lesions, which were more directly responsible for the fatal result than the chest wounds. Eleven of these 16 had wounds passing through the diaphragm into the abdominal cavity. Two had very septic wounds of the pharynx and trachea, and required tracheotomy. Two had extensive gas-infected wounds of the chest wall. One had a lacerated wound of the pericardium, and the patient became so collapsed that the operation had to be abandoned. In these 16 cases death did not occur, in our opinion, from the injury to the lung or pleural sac, and it may be justifiable to exclude them in estimating the mortality.

If it is permissible to exclude them,

The rate of mortality in the 51 remaining cases was ... 33.3 per cent.
And the recovery-rate was ... 66.6 "

If, however, one includes these 16 cases,

The rate of mortality in 67 cases was ... 49.25 per cent.
And the recovery-rate was ... 50.75 "

More instruction can, however, be obtained from the following tables:

Operation Results.

Class.	No. of Operations.	Recovered.	Per-centage.	Died.	Per-centage.
1 ...	29	10	34.49	19	65.51
2 ...	23	10	43.47	13	56.52
3 ...	15	14	93.3	1	6.6
4 ...	—	—	—	—	—
Totals ...	67	34	—	33	—

Pleura Closed.

Class.	Total Closed.	Recovered.	Per-centage.	Died.	Per-centage.
1 ...	12	5	41.6	7	58.3
2 ...	7	4	57.14	3	42.8
3 ...	6	6	100.00	—	—
4 ...	—	—	—	—	—
Totals ...	25	15	—	10	—

Pleura Drained.

Class.	Total Drained.	Recovered.	Per-centage.	Died.	Per-centage.
1 ...	17	5	29.4	12	70.5
2 ...	16	6	37.5	10	62.5
3 ...	9	8	88.8	1	11.1
4 ...	—	—	—	—	—
Totals ...	42	19	—	23	—

Types of Infection.

The fluid from the pleural cavity was not examined in every case, but of the 35 examined for us by Captain R. L. Thornley—

Streptococci were present in ...	72.7 per cent.
<i>B. aerogenes capsulatus</i> was present in ...	54.5 "
Pneumococci were present in ...	36.3 "
Staphylococci " " ...	27.2 "
<i>B. influenzae</i> " " ...	27.2 "

The *Bacillus tetragenus* was present in 18.1 per cent., and a spore-bearing organism (probably that of malignant oedema) and a diphtheroid bacillus were present in 9.09 per cent. of the cases examined. In the majority of cases a combination of these organisms was found; in four cases only was a single type of organism present.

Results have shown that even although anaerobic bacilli or streptococci are present the pleural sac can be completely closed with success, the wounds healing by first intention. Consequently we are increasingly inclined to disregard the nature of the infection provided that approximately clean surfaces can be left internally.

We feel that in an apparently simple case of haemothorax with increasing severity of symptoms better and quicker results will be obtained by opening the chest as described, and cleansing and closing the pleural cavity, as has been done by Major Gask at another casualty clearing station. We have since operated on several such cases, so far with complete success in every case.

In cases in which streptococci or anaerobic organisms have been found a sharp look-out should, however, be kept for reaccumulation of fluid or deterioration in the patient's symptoms.

By far the commonest cause of death in the chest cases with no other injury was septic bronchopneumonia of the uninjured lung. It was for this reason that we gave creosote as a prophylactic measure and also antistreptococcus serum in severe cases. There is no accurate means of testing the value of these measures, but the impression gathered from their use was favourable.

The whole object underlying early operation in these chest wounds is the rational one of trying to secure early recovery, not only of the patient but of the function of the lung. This involves thorough removal of all possible sources of septic infection, whether in the form of dead tissue, devitalized tissue, infected fluid or blood clot, clothing or other foreign body, followed by closure of the pleura after expulsion of air from the sac.

When this complete operation can be thoroughly carried out before the patient has sunk too low the results are distinctly encouraging. The patient immediately becomes comfortable and his breathing improves. Breath sounds can often be heard over the lung within a few hours. The patient has a good prospect of a quick recovery to normal health with a lung doing its work in a normal way.

NOTES IN CONNEXION WITH THE ABOVE ARTICLES ON SURGERY OF THE CHEST.

BY

TEMPORARY COLONEL H. M. W. GRAY, C.B., A.M.S.

It is most gratifying and encouraging that such good results have been obtained from operative interference in these very distressing cases by surgeons who have hitherto had but little experience in the surgery of the chest. The types dealt with were nearly as fatal as are non-operated penetrating wounds of hollow viscera of the abdomen. Closed "E and E" or small "E only" wounds may be compared with similar wounds of solid abdominal organs.

I think it was in February or March, 1916, that Captain Roberts and I first deliberately undertook one of these operations at a base hospital. An almost spent bullet had smashed the ribs in the left axilla and had lodged in the anterior border of the left lung close to the heart. The bullet was extracted easily enough, and the chest wall was stitched up completely. Unfortunately the patient died of septicaemia four days later. It was somewhat discouraging, but we procured intratracheal anaesthesia apparatus in order to be better equipped for the next case. As stated, such cases are very rare at the base, and transference to the front was necessary before either of us could develop the operation. The accounts now given represent that development. From what I can learn, French surgeons operate in the same manner. Major Gask in another area has been carrying out similar procedures, and has operated on a considerable number of cases.

The results obtained in these severe chest operations are better than those obtained by the same surgeons in abdominal operations performed during the same period. The abdominal field was not "new ground" to these surgeons. One would therefore expect that greater experience in thoracic surgery will lead to much better results. Captains Roberts and Craig laboured under the disadvantage of having no x-ray apparatus. The localization, previous to operation, of a lodged foreign body, is of the utmost importance in many of these cases, but their cases could not wait. In some the patient's condition was so bad that x-ray examination was purposely omitted. It was judged that practically all would have succumbed to the effects of further transport or delay. It is difficult by description to indicate how bad some of them were. They were, on the whole, of a kind rarely seen in base hospitals. They formed 35 per cent. of all penetrating chest wounds in the casualty clearing station where Captains Roberts and Craig were working.

These cases should be sent on, as soon as their condition permits, from the field ambulances to the casualty clearing stations, because, as will have been appreciated from a study of the papers, the sooner they are operated on the better is the chance of recovery. A *laissez faire* policy is no longer justifiable.

The operative procedures are very rightly compared with those which have been found essential for uniform success in wounds of the knee joint. The principles of treatment of war wounds in France should be the same whatever part of the body is affected. The application of these principles must be modified according to the local character of the wound, and by consideration for the patient's general condition. The possibilities attending their application—the results, that is to say—depend chiefly on the capacity and judgement of the surgeon.

Intrathoracic Manipulations.

Intrathoracic manipulations may be carried out safely with much greater freedom than has been supposed. It is curious that in most cases the pleura, both parietal and visceral, may be handled and wiped without causing pain, and this although only a few of the intercostal nerves may have been "blocked" by local anaesthetic. It is equally curious, therefore, that some patients complain severely when such manipulation is attempted. Unless it is roughly pulled upon, the lung is apparently equally insensitive. The same remarks apply to the pericardium and heart, but I have never seen a case in which the parietal peritoneum and abdominal viscera could be handled, under similar conditions, without causing severe pain.

Methods of Causing Expansion of the Collapsed Lung.

Special positive pressure apparatus is not essential, although it would prove of great advantage in most of the operations, especially when it is considered safe to expand the lung before the pleural cavity is closed. The writers of these articles have described how this expansion may be brought about. The air in the pleural cavity may also be aspirated after the wounds are closed. It is interesting to note the auscultatory phenomena during this procedure.

Time for Operating.

While the patient should not usually be subjected to operation in cases of open "sucking" wounds until the shock, respiratory distress, and cardiac frequency and irregularity have been alleviated, yet persistent haemorrhage may compel immediate operation. In many cases also mere plugging or suturing of the wound fails to relieve the dyspnoea. This is sometimes found when wound of the diaphragm is present. In these cases operation should not be delayed. If the cardiac action is fairly regular, the operation can be carried out, and it is, indeed, in these patients that its effects are most impressive.

I would urge very strongly that these operations be undertaken at the earliest possible moment. The best access for these cases is got by excising six inches or so of the fifth rib in the axillary line. By delay sepsis is allowed to get a strong hold, and then it may be dangerous to close the chest. In the early stages of infection, when the organisms are still breeding only in the blood clot or pleural effusion, it is apparently safe to close completely, even though gas bacilli or streptococci are present. In later stages streptococcal infection is much more dangerous than that by gas-forming organisms.

Suture of Wounds in Diaphragm.

As remarked by Captain Anderson, Captain A. L. Lockwood¹ deserves the credit of having shown the necessity for suture of diaphragmatic wounds during abdominal operations. It is of equal importance in chest cases, and should be done as a first step after excising the parietal wound. (See later, under "Multiple Injuries.")

Closure versus Drainage.

The striking improvement which occurs when the wound is closed by suture, plug, or strapping is possibly due chiefly to the fact that the mediastinum is steadied, and that then the opposite lung and the heart can function more easily. The effect is still more rapid and remarkable when the chest wall is closed by suture at the end of the operation. In some cases the change in the patient's condition is really magical. In late cases, where intrapleural sepsis has developed fully, there is not the same amount of distress when the chest is opened, possibly because the mediastinum is more fixed by inflammation.

It is very desirable to close the chest completely in every early case. I believe that by so doing the mortality will be lessened.

During one month 193 cases were operated on at certain casualty clearing stations, with drainage of the pleural cavity; 99 (50 per cent.) of these died, 57 cases were closed completely, and 17 died (29.8 per cent.) It appears, therefore, that the operation with complete closure is 20 per cent. better than the operation with drainage. It may be necessary to reopen the chest on account of the development of intrapleural sepsis or to remove a foreign body, but by the time this is necessary the patient has been tided over his dangerous period, and when the pleural cavity is drained there is not any more respiratory distress than after an ordinary empyema operation.

When old adhesions fix the wounded lung to the parietes and there has been much soiling along the track of the missile, it is advisable to leave the wounds of the lung and chest wall open. In these cases bipp, or one of the recently used paraffin packs, makes very suitable dressing, easily removed. Early secondary suture can usually be effected.

The Use of Local Anaesthesia.

It may be that a patient can be steered successfully through the operation under general anaesthesia, but it is far safer to dispense with this altogether, if possible, owing to the evil effect which is otherwise exerted on the unaffected lung already predisposed to inflammation. It

is remarkable how the lung of the operated side may expand and remain healthy, according to reliable clinicians, while the other lung develops well-marked signs of inflammation. As Captain Anderson states, this fact may really turn the scale favourably in the patient's chances of recovery—another reason for complete closure.

The patient should be well "doped" before operation. He should be made very drowsy, but at the same time be capable of being roused and of doing what he is asked to do. Omnopon, or some similar preparation of opium, is more satisfactory from many points of view than the alkaloid morphine alone. Scopolamine is given with advantage with the first dose, but is omitted from the second, if a second dose is necessary. The same amount of care in preparation of the patient and administration of the local anaesthetic should be exercised as when a general anaesthetic is chosen for these cases. A specially skilled anaesthetist is usually selected in the latter case.

If he is in any way "fit," the patient should be warned in a tactful way that he may feel extraordinarily distressed and apprehensive during the operation, that, indeed, the operator expects this, but that he should try to lie and breathe quietly, that struggling and excitement will only increase his distress, and that the symptoms will pass off very quickly when the operation is finished. If, in spite of such warning, he is very restless, a small amount of general anaesthetic should be given.

The Importance of Speed.

Speed is of the utmost value in certain cases; therefore the plan of the operation should be mapped out beforehand and understood by all assistants. Suitable instruments should be handy at each stage of the operation, and a sufficient number of sutures, on needles of various sizes and curves, should be prepared. The operator must not "lose his head" when things become alarming. He is assured of a speedy peace when the pleural cavity is closed. It is wonderful, at this alarming stage, what a soothing effect a few whiffs of general anaesthetic may have, but the anaesthetic should be given for as short a time as possible. It is in these circumstances that a positive pressure apparatus would probably be of great value.

In Multiple Injuries the Chest Wound takes Precedence.

When a "sucking" wound of the chest is accompanied by an intra-abdominal injury, the chest should always be dealt with first. Sometimes the abdominal condition can be effectively treated by prolonging the chest wound downwards and forwards. In such cases care must be taken to suture the diaphragm (air-tight) to the chest wall around the periphery of the wound. It is astonishing to what a height and at what tension the diaphragm can be sutured in this way, with practically no subsequent distress to the patient.

Introduction of Antiseptic Fluid.

If the foreign body cannot, for various reasons, be removed at the primary operation, a small quantity (1 to 3 oz.) of one of the recently devised antiseptic solutions (flavine, brilliant green, iodoform 1 per cent. in liquid paraffin) should be left in the pleural cavity. This may have the effect of delaying or limiting septic processes until the foreign body can be dealt with at a second operation. When the intrapleural conditions have been thoroughly "cleaned up," I doubt whether the use of such fluids is essential, but, so far as one can judge, they are not harmful.

Conclusion.

It must be remembered that the operation is undertaken with two great objects in view—(a) to prevent sepsis getting a hold, and (b) to tide the patient over the dangerous period. Complete closure of the chest wall attains these objects more successfully than when drainage is used.

Patients subjected to such operations should not usually be evacuated until about ten to fourteen days after operation.

PLASTIC TRANSCOSTAL THORACOTOMY.

BY

E. M. COWELL, M.D., B.S., F.R.C.S.,

CAPTAIN R.A.M.C.(S.R.).

THE development of thoracic surgery as a special department of military surgery has made great strides in the past year. Thanks to the pioneer work of Major G. E. Gask, D.S.O., R.A.M.C., and M. le Médecin-Majeur Duval, of the French Medical Service, chest surgery has now been placed on a sound basis, and in the hands of experts is yielding good results. The technique of thoracotomy and subsequent manipulation of the lung as practised by these operators is simple and quick. The complete closure of the chest, however, is not so easy, and in many parts of the chest wall is extremely difficult owing to the thinness of the pleura and the rigidity of the thoracic wall. By means of the plastic operation I have devised this difficulty would appear to be overcome; it is now possible to close the chest soundly in a few moments, as against the ten to fifteen minutes or more of the usual methods.

Method of Operating.

To open the chest in a patient of average size the selected rib is exposed for about 5 in. (22 to 23 cm.), the periosteum is incised, and the cut A made about 1½ in. (4 cm.) long, ½ cm. from the lower border of the rib, the saw being directed upwards so that the rib is sawn with bevelled edges. As soon as the chest is opened a key saw is introduced and the cut B made. As indicated in Fig. 1,

FIG. 1.

the cut stops just short of the rib margin in order to avoid injury to the intercostal vessels. From this point the third cut, C, is made in such a way that the cut end of the rib is rounded off and no sharp points are left which may tear the glove.

In the same way the cuts B' and C' are made on the other side of A, and the sawing is complete. In order to facilitate the rib section, a special key saw has been devised with a blunt end and double edge, so that one can saw in either direction, that is, forehand or backhand, without having to take out and reintroduce the saw. The two pieces of rib with attached pleura are now turned outwards on the hinge of intercostal tissue as shown in Fig. 2. In this way an opening 3.5 cm. wide is pro-

FIG. 2.

vided, which is easily increased to 6 cm. by "spreading" the adjacent ribs in the usual way. Through this opening an average size hand can easily be passed, and the required manipulation of the lung carried out.

To close the chest two or three stitches of stout catgut or silkworm-gut are passed round the rib, care being taken to keep the point of the needle against the rib to avoid the vessels and nerve. The sections of rib are now turned back into their original position, where they fit into place like pieces of a "jig-saw" puzzle; the stitches are tied, and in a few moments the chest is closed, with the cut edges of pleura in close proximity. A layer of muscle and fascia is stitched over the rib to reinforce the line of suture, the skin incision is closed, and the chest wall is restored to normal.

Indications for the Operation.

The main indications for this thoracotomy in war surgery are: (1) Removal of a large foreign body; (2) suture of torn lung; (3) exploration of haemothorax with evacuation of blood clot and septic material.

The method can be applied when the chest is to be opened through either the wound of entry or exit, since it is quite easy to saw the two portions of traversed rib longitudinally; and the subsequent closure is so much simplified.

Lastly, a modification of this method affords a great saving of time in those operations for infected haemothorax where "air-tight" drainage is so advantageous. According to Elliott and Henry,¹ "This procedure (that is, sewing pleura, muscle, and skin in layers tightly round the tube, after resection of rib) adds at least fifteen minutes to the time taken for the operation, for it is not an easy matter to sew up inelastic pleura." Two inches (6 or 7 cm.) of rib are exposed, a disc 1 cm. across is cut out with a trephine and the rest of the operation completed as described above. If a larger drainage tube is needed, the opening can be widened with nibbling forceps. The pleura, by means of its attached piece of rib, is closed with two stitches; the tube is air-tight and the whole proceeding has taken but a few minutes.

In civil practice this operation will afford an ideal route for exploratory thoracotomy, pneumectomy, etc.

Advantages of the Method.

This thoracotomy is simple and quick, provides perfect access to the chest contents, and moreover ensures a rapid perfect closure.

It was originally with the idea of saving time that this operation was thought out. One of the lessons war surgery has taught is that not only the recovery of the individual but the welfare of many patients often depends to a great extent on the speed at which the surgeon works.

Again, the operation which gives as an end result the closest approximation to the original normal anatomical condition, without risk or other disadvantage to the patient, is always the ideal at which one should aim.

THE EARLY OPERATIVE TREATMENT OF PENETRATING GUNSHOT WOUNDS OF THE CHEST.

By FRANK J. HATHAWAY, M.D.,

SURGEON, KING EDWARD VII HOSPITAL, WINDSOR;
LATE CAPTAIN R.A.M.C.

THE necessity of early operation in gunshot wounds of the chest is now established. There is no doubt that many lives are saved, and convalescence shortened by early and complete operation in a casualty clearing station, and I hope these short notes of my own experience may be of value.

*Nature of Wounds and of Projectiles which
Caused Them.*

(a) Clean through-and-through wounds caused by a rifle bullet or shrapnel ball, with small wound of entrance or exit, require no early operation. Aspiration of the haemothorax may be necessary. Frequently the shrapnel ball is under the skin and may be removed.

(b) However, a rifle bullet or shrapnel ball frequently strikes bone, scapula or rib, and makes a large wound of exit. This, if not operated on very soon, becomes very septic, and, an open track being left to the pleura and lung, gives rise to secondary complications. Such cases should be dealt with, the exit wound completely excised down to the pleura, all loose fragments of bone removed, the wound cleansed, and sewn up if possible.

(c) Tangential wounds of the chest are amongst the most fatal when associated with much rib damage. Fragments of bone and clothing are driven into the pleura and lung, and there is a large sloughing wound with an open track to the pleura. The diaphragm is frequently injured, and there may be penetrating wounds of abdominal viscera. In all of these cases a complete and careful excision of the whole wound is necessary. Pleura and lung must be

cleansed of bone fragments and cloth, and the diaphragm closed if wounded. If necessary more rib must be excised in order to be well clear of damaged tissue and to allow the wound to be closed.

(d) Through-and-through wounds caused by shrapnel or high explosive have large entrance and exit wounds with ragged much-damaged edges. In these both the entrance and exit wound should be completely excised down to the pleura, all damaged tissues removed, and the wound closed if possible by suture.

(e) The large group of cases is that in which a missile is retained in the chest cavity. Rifle bullets and shrapnel balls can be left, the progress of the case watched, and if sepsis supervenes they can be removed at the base. But the case is different with ragged pieces of shell. Here there is much laceration, and fragments of clothing are carried in. If the fragment is really small it may be left. If large and in an accessible position it should always be removed. Toilet of wound, for example, excision of all lacerated tissue down to the pleura, should be carried out, the metal fragment removed if possible, and the wound closed in successive layers.

Preparation for Operation.

Time to Operate.—Wait for shock to pass off. To get clean results, operation should be done in the first twenty-four hours. This follows experience of ordinary wounds. Thus, if early and completely excised wide of damaged tissue, and sewn up, they should heal by first intention.

X ray is essential. A plate should be taken, and should show bone as well as fragments embedded in lung. The metal fragment must be carefully localized.

Anaesthetic.—Local anaesthesia with novocain is the best. If necessary, a few whiffs of chloroform and ether can be given. Frequently, with multiple wounds, a general anaesthetic is necessary, and in my experience is well taken. No intratracheal pressure apparatus is necessary.

Operation.

Wide and careful excision of wound and damaged tissues is the first thing. Resection of rib. It is necessary to allow plenty of room, so that a good view may be obtained and the whole hand passed into the pleural cavity. To do this wide resection of rib is necessary; three inches may be removed from two adjacent ribs or six inches of one. The pleura is then exposed. If there is a large opening, with pneumothorax, the edges should be excised, and the hand put into the pleural cavity and the metal fragment removed. If the wound is small, with little or no sucking in of air, a small incision should be made into the pleura, and the lung quickly grasped with a pair of toothed forceps. Moynihan's or tissue forceps are excellent. The lung is then firmly pulled to the wound, and the incision in the pleura enlarged. It is then possible to gradually evacuate the haemothorax and only allow a small amount of air to enter. The grasping of the lung with forceps and firmly pulling on it prevents it from collapsing, and, in my opinion, should always be carried out, for sudden and massive collapse of the lung is one of the great dangers of the operation and should always be prevented if possible. After exposure of lung, the metal fragment can often be seen and picked out, for, as Colonel Elliott and Captain Henry have shown, the lung itself offers little resistance, and the fragment either tends to pass right through or remain in the pleural cavity or surface of lung. Some fall to the most dependent part of the pleural cavity. If, however, the metal fragment is embedded in the lung, the wound of lung should be sought for and the track of the missile followed up; this can be done with the knife, the track being held in good view, or with a thermo cautery. Another method is to insert the finger in the track, feel for the fragment, and extract with forceps or scoop, but the obvious danger of this is detachment of a clot from a large vessel and not being able to see what one is doing. Any haemorrhage is now controlled. If large, the wound of lung should be sutured with catgut. The pleural cavity should be washed out with flavine or Dakin's solution; by this fragments of clothing which may have been overlooked are removed. Some flavine may be left in the pleura.

The pleura is then, if possible, completely closed, leaving any infection "to be dealt with by the natural power of the pleura to dispose of infection," which has been shown

by Colonel Elliott and Captain Henry to be very strong. The parietal pleura should be sewn together if possible; if the opening is too large then it may be stitched to the lung and visceral pleura. The skin and muscle are brought together with a few interrupted sutures. Where the skin, however, cannot be closed the wound should be firmly packed with gauze, a salt or paraffin pack, and strapped.

After-Treatment.

This depends on the progress of the case. The majority, where the ideal early operation can be carried out, should do very well and make an uninterrupted recovery. It is extraordinary how quickly a lung will expand after the pleura is closed. If much blood should collect it should be aspirated. If gas infection or empyema supervene the ordinary treatment should be carried out and the pleural cavity drained. This can be done through the original wound if dependent; if not, a lower rib should be resected and the cavity drained.

Localized Collection.

A local collection of pus round the wound may develop and require evacuation.

Conclusions.

The ideal methods of modern war surgery are (1) early operation, (2) complete excision of wound and damaged tissues, (3) removal of metal fragment and clothing, (4) mechanical cleansing of wound (the use of strong antiseptics is to be avoided), (5) complete suture of wound. Provided one can get *early and complete* operation, there is far more danger from secondary than from primary infection.

The treatment of wounds of the chest, therefore, follows the same lines as those of the abdomen, head, knee, or other joints; they require just as early operation, and it will be found that the results are just as good.

THE TREATMENT OF GUNSHOT WOUNDS OF THE ELBOW-JOINT: A PLEA FOR PRIMARY EXCISION.

By C. MANSELL MOULLIN, F.R.C.S.,

LIEUT.-COLONEL R.A.M.C.(T.F.),

2ND LONDON (CITY OF LONDON) GENERAL HOSPITAL.

THE ultimate results of the injuries inflicted in gunshot wounds of the elbow-joint cannot be regarded as satisfactory. In the majority there is complete, or almost complete, ankylosis. If the wound pursues a thoroughly aseptic course, and the injury is confined to the olecranon or one of the epicondyles, the joint may regain a fair range of movement. But when, as in the majority of instances, the wound becomes septic and the bones are badly comminuted, especially if the lower end of the humerus is involved, the results are deplorable. Effective drainage is very difficult to carry out, even if Carrel-Dakin's method is employed. Acute septic inflammation nearly always follows. The whole region of the elbow becomes immensely swollen. Accurate reposition of the broken fragments is out of the question. A great deal of new bone is thrown out, many of the fragments become necrosed, and after a prolonged illness running into many months the elbow is left either ankylosed at an awkward angle, so that often the patient cannot use his hand to feed himself, or at best with a limited degree of flexion and extension, with rotation at the shoulder-joint as a clumsy substitute for supination.

The results of primary excision of the elbow-joint, on the other hand, are wonderfully good, provided sufficient bone is removed—that is to say, the lower end of the humerus just above the level of the epicondyles, the whole of the head of the radius and the ulna at the same level. I have notes of five cases in civil practice performed for injury in which the joint was excised in this way, with complete restoration of movement and recovery of the muscles so that the arm was to all intents and purposes as strong and as useful as it was before. Even if the conditions are such that the wound is already infected, the drainage is so free that a serious degree of sepsis can usually be avoided, and there is not that enormous mass of callus thrown out, binding everything together and

locking the fragments so that they cannot move. It is true that, owing to the necessity of re-educating the muscles of the forearm, which have been separated from their attachments, it may be twelve months before recovery is complete, but the fingers and wrist can be used after the first few weeks, and, if a suitable splint is provided, the elbow as soon as the wound is sound.

The operation, of course, is much more tedious when performed for injury than when performed for disease. The muscles cannot be so easily separated from their attachments, and when the bones are comminuted and the fragments displaced, there is need of careful dissection, which may take up valuable time. But provided the operation can be done before septic infection has spread far, and sufficient bone is removed, the results are so different from those of the conservative method of treatment that there is no comparison between them.

It is not, of course, possible to say whether the conditions at a casualty clearing station are such as to allow a proceeding of this kind to be carried out at a time when every moment is required, but the only conclusion at which one can arrive from three years' experience at a base hospital, is that if primary excision of the elbow were adopted more generally a great deal of illness and suffering would be saved and much more useful limbs would be left. Excision can, of course, be performed later with an excellent result, and doubtless in many cases it will be, but this means a second operation of some gravity and a second period of convalescence before recovery is complete.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

REAMPUTATION.

THE following technique has been evolved in the Dartford War Hospital in the large number of reamputations performed here. Various points were gleaned from various sources, and among the most valued recent suggestions is that of Major W. A. Chapple¹ to employ button sutures of relaxation in the deeper parts of the flap.

Preliminary.—During the waiting period use a weight and pulley with adhesive plaster to bring down the skin. Clean up the surface as thoroughly as possible but do not wait for all small pockets to become healthy. A fortnight is long enough.

Stage 1.—Apply a tourniquet. Curette the whole surface, especially any pockets, whilst flushing thoroughly with a dilute antiseptic.

Stage 2.—(Usually needed but not always.) Make a free incision down to the bone on the outer side of the limb, exposing it to above the intended line of section.

Stage 3.—Make a circular incision round the bone near its end, through the periosteum, above the point at which there are spurs and plates of new bony deposit; but where these extend up the shaft far, then at 1 in. from the surface of the stump. Carefully peel the tissues, including the periosteum, off the bone, splitting them through the outer incision.

Stage 4.—Cut the bone either with a Gigli saw, which we have been frequently employing for the past eighteen months, or by the ordinary saw if the tissues can be retracted sufficiently. Use a cloth retractor with a hole in it to slip over the end of the bone. I devised a special metal retractor but it did not work satisfactorily.

Stage 5.—Study the stump; see whether any of the fleshy mass needs to be trimmed to enable the skin to cover it. Free the skin from the underlying muscular tissues for 1½ in. to 2 in.; avoid scoring the subcutaneous fat.

Stage 6.—Remove the tourniquet; check all haemorrhage with ligatures and hot wet swabs.

Stage 7.—Suturing. Unite the periosteal sheath over the bone by a catgut mattress suture. Place two or three catgut sutures into the muscles, approximating them or inverting them as the case requires. Put in two or three silkworm-gut sutures, piercing rubber tubing in the way described by Major Chapple, compressing the flaps into good apposition.

One small rubber drain should be placed from the deepest part by the bone to the outer incision; another at the inner corner of the wound just under the skin flaps, which should be sutured at intervals of ½ in. A very useful skin suture is often employed by my colleague, Mr. Bost. It pierces the skin ½ in. from the edge then returns ½ in. from the edge, which is thus slightly everted and closely apposed.

Since this technique has been used (1) we have taken to earlier operation; (2) we have removed rather less bone; and (3) we have had better results in the way of primary union.

¹ BRITISH MEDICAL JOURNAL, August 25th, 1917, p. 242.

Several officers have taken part in the operating. My thanks are also due to Colonel Bond for permission to publish this.

Major A. NEVE, F.R.C.S.E.,
Surgical Specialist, Dartford War Hospital.

Reviews.

MANSON'S TROPICAL DISEASES.

WHEN the first edition of Sir PATRICK MANSON'S *Tropical Diseases* appeared, in May, 1898, it marked an epoch, for it was the first volume in which an attempt was made to bring together and render available for the working doctor in one portable volume the large mass of new material with regard to diseases of the tropics which had then already accumulated. How great was the need of such a book was shown by the fact that the first edition had to be reprinted three times within nine months of its appearance and that a new and revised edition was called for in 1900. The fifth edition appeared in May, 1914, just sixteen years after the first. The new edition¹ has been thoroughly revised, but, we are glad to say, only a little enlarged. The text appears to have been revised throughout, but the most important accessions to knowledge which it notes as having been made since the fifth edition are those relating to the extracorporeal life-history of *Schistosomum haematobium*, due to the researches of Dr. Leiper, and the demonstration that dengue is conveyed by *Stegomyia calopus*. An alteration in arrangement of some significance is that rat-bite disease has been removed from the section on general diseases of undetermined nature to that on fevers, and that the chapter on pellagra which appeared in the last edition among fevers is now relegated to the section on general diseases of undetermined nature. In this chapter on pellagra a cautious attitude is properly observed. Sambon's hypothesis, which attributed it to a protozoal organism, transmitted by some blood-sucking midge belonging either to the Chironomidae or to the Simuliidae, is fully set out, but Goldberger's failure to communicate the disease and his consequent rejection of a germ cause are also noted. Additional evidence in favour of the view that the disease is due to defects in diet has recently been afforded by observations in America, as noted elsewhere in this issue (p. 593).

The chapters on mosquitos and tsetse flies and ticks have been revised by Lieut.-Colonel Alcock, C.I.E., I.M.S., lecturer on medical entomology and general medical zoology in the London School of Tropical Medicine. The numerous illustrations in these chapters are of real value, for they not only help the comprehension of the facts established with regard to the life-history of the parasite, but will be found of practical utility for reference by workers engaged in the recognition and investigation of malaria and trypanosomiasis in districts where it is impossible to carry about a large library. No considerable alterations appear to have been found necessary in the chapter on dysentery, but a short section is inserted on *Lambia* infection, and also a note on the isolation of the bacillus from the stools.

In spite of the many editions through which it has passed, the book retains the stamp put upon it in the first. It is the work of a master thoroughly familiar with a subject, to which, both directly and through his stimulating influence on his pupils, he has contributed so largely. Theoretical considerations are fully stated, but always along with the facts and observations upon which they are founded, as well as those which may be held to militate against them. This plan involves the inclusion of an immense number of details, which must be continuously increased or corrected as research progresses. It would be a very laborious undertaking to compare the new edition with the last on every point, but so far as we have carried this process we invariably find new work noticed. The new edition will maintain and extend the reputation of the work as a sound guide for the use of students and practitioners; it is comprehensive, without being too large for the practical purposes of a physician in the tropics.

X RAYS IN THE DIAGNOSIS OF DISEASES OF THE ALIMENTARY CANAL.

*The Roentgen Diagnosis of Diseases of the Alimentary Canal*² is the title of a book written by Drs. CARMAN and MILLER, respectively the head and the first assistant in the Section of Roentgenology, Division of Medicine, of the Mayo Clinic. The aim of the authors has been to select and arrange in a systematic manner those things which seem not only to be true but worth while, and especially those which they have verified by their own experience, and the result is a reference book which should be of very great value. In its general scheme the idea has been to follow the gastro-intestinal tract through from beginning to end, allotting a chapter to each definite condition of the part under consideration, giving a short reference to the principal published papers at the end. Arranged in this manner, a single chapter becomes a short monograph, complete in itself, and yet it remains an essential part of the whole scheme, as one chapter leads on to another. Any extensive description of apparatus has been avoided, but the general technique of examination is fully discussed, and an important point is made in Chapter II, in which the principle is laid down that each roentgenologist should have some customary routine to follow in order that his comparisons should be made on a uniform basis, but that at the same time, whilst following this routine, it should be made flexible to meet exceptional circumstances. Emphasis is also laid upon the fact that routine will not alone make diagnoses, but that the interpretation of findings, which can be learnt by experience alone, is quite as important as technical methods.

The vast amount of material at the author's disposal in the Mayo Clinic is evident throughout the whole book. Proof of this is seen in the chapter on syphilis of the stomach with its many illustrations of this condition. It is quite evident, as is pointed out, that syphilis cannot be diagnosed from the x-ray appearances, which would as a rule suggest cancer or ulcer; but the discrepancy between the extent of the lesion and the general condition of the patient, who is often under the cancer age, and is anaemic rather than cachectic, and is not markedly weakened or emaciated, are points which should give rise to suspicion.

In discussing the x-ray diagnosis of duodenal ulcer it is pointed out that the condition is so important and frequent that more than 2,300 cases have been proved by operation at the clinic. Careful investigation has convinced the authors, who had previously been sceptically inclined, that Cole's sign—namely, deformity of the duodenal contour—a "direct" sign of the presence of a duodenal ulcer, is of the greatest diagnostic value. There are many illustrations showing this condition, and these are the more valuable inasmuch as the cases have gone to operation and the x-ray diagnosis has been confirmed. A few rare conditions, not without interest, are to be found here and there throughout the book, but essentially the radiographic conditions illustrated and described are such as occur daily in any large x-ray clinic.

Taken as a whole this work is a valuable record of systematic and careful observation of cases; it is well got up; the letterpress is excellent; the illustrations are well chosen, profuse, and typical of the conditions described. It is the best book which has as yet been published on the subject, and it should become a standard textbook.

NOTES ON BOOKS.

WE have on several occasions called attention to the excellence of Mr. MUIRHEAD BONE'S illustrations in the periodical, *The Western Front*,³ published for the Government from the offices of *Country Life*. The first five numbers have been collected into a volume containing, with extra letterpress and index, 100 plates of places and incidents with the British armies in France, in munition works in England, and with the Grand Fleet. The volume is of permanent interest, for Mr. Bone has the power of giving not only a transcript of a landscape which is faithful to its outlines, but can record its spiritual effect

² *The Roentgen Diagnosis of Diseases of the Alimentary Canal.* By Russell D. Carman, M.D., and Albert Miller, M.D. Philadelphia and London: W. B. Saunders Company. 1917. (Roy. 8vo, pp. 558; 504 illustrations. 6 dollars net.)

³ *The Western Front.* Vol. I (15s.); monthly numbers 2s.). *Generals of the British Army.* Part I (5s.). London: Published for the Government by *Country Life*, Ltd.

on the spectator, as witness his sketches of the Somme, where the sense of distance and the ideas of remoteness and desolation carry to the eye of the mind a picture the truth of which those who have looked across the country itself will be the first to acclaim. No other pictures we have seen, whether of artist or photographer, approach these in conveying to those who have stopped at home a true impression of the places in which their sons have been fighting, the burrows and billets in which they have dwelt, and the towns and villages through which they have marched. The letterpress is just full enough to recall the times and circumstances in which the drawings were made. The September number shows the artist in his most varied form. The fourteen drawings in France give us, in addition to impressionist sketches of the armies, three finished drawings of undamaged France—one of the exquisite doorway of a house built for one of Napoleon's generals, one of the quaintly beautiful square in Hesdin, and another of Rollencourt village with its church and surrounding trees and the wide landscape beyond. The other seven drawings in this number are of the sea, the last being a vivid picture of the bridge of a merchant ship. A character sketch of each man could be written from it, and the whole is flooded with the light that fills the "high and lofty" bridge house by day. The October number contains drawings more in the line of work which first brought Mr. Bone reputation. They are all concerned with ship building, and include several drawings of standard ships in various stages; one, a shipyard seen from a big crane, and another, entitled "the seven cranes," show the artist of machinery at his best. The same publishers have issued the first part of another periodical, *Generals of the British Army*. It contains twelve portraits done from life, mostly in France, by Mr. FRANCIS DODD. They have the effect of coloured pastels and are admirably reproduced. They are not smooth and flattering, but give the man as he is, with a strong impression of the mind and character behind the outward showing. The first, of Sir Douglas Haig, is not only an extraordinarily good likeness, but in the expression of the face and the whole attitude and pose of the alert figure tells the qualities which have brought him to the great place he holds. The last portrait is of General Smuts, standing full face, looking very straight to his front. Each portrait is accompanied by a short biography. It may be interesting to note the nationality and age of the eight generals here portrayed who have commanded armies. Two, including the Field Marshal, are of Scottish birth, and both are aged 56; four are of English family, aged 53, 55, 56, and 60; of the two others, both aged 47, one belongs to an Irish and the other to a South African family. The portraits of Sir Douglas Haig and General Smuts have also been reproduced on a larger scale for framing, as well as portraits of Admirals Jellicoe and Beatty, which appear to belong to another series we have not seen.

MEDICAL AND SURGICAL APPLIANCES.

Combined Scissors, Forceps, and Sponge-holder.

W. B. AINGER, F.R.C.S., Captain R.A.M.C.(T.F.), writes: A glance at the accompanying sketch will at once make clear the utility of this instrument, which combines in itself the functions of scissors, forceps, and sponge-holder. When the scissor action is required the instrument is grasped as

one would an ordinary pair of scissors, with the hand pronated. When the forceps or sponge-holder action is required all that is needed is to supinate the hand completely. The instrument is designed to obviate the necessity for constantly washing the hands, steeping them in lotions, etc., and all the ritual, so often imperfectly carried out, which goes to the performance of the simplest dressing. The instrument should be kept in a jar with the blades immersed in strong lysol and the handles

exposed. Before use the blades should be rinsed in some weaker solution and then, on completion of the dressing, once more rinsed before returning to the jar. The instrument has been made for me by Mr. Alfred E. Dean, Leigh Place, Brook Street, Holborn, E.C.1.

THE WELFARE OF THE BLIND.

We gave in the JOURNAL of August 18th an account of the general character of the report¹ presented by the Departmental Committee on the welfare of the blind, appointed in May, 1914, and mentioned its principal recommendations. The matter, however, is of so much importance and possesses so much interest for the medical profession that it appears desirable to give a more extended notice of the scope of the inquiry.

The Number of the Blind.

The report of the Committee states that according to the census of 1911 there were 33,965 persons (males and females in nearly equal proportions) returned as totally blind. Of these 2,184 were under the age of 15 years. The census returns specified 8,693 as "occupied," including children of 10 and upwards. Figures obtained by the Committee from institutions indicate that approximately 3,000 blind persons are occupied in workshops and institutions. It endeavoured to collate statistics as to the capable blind who were unoccupied; the data is incomplete, but a conservative estimate points to there being not less than 3,000 blind persons capable of training and employment, but unoccupied. In July, 1914, there were 12,015 persons in receipt of outdoor poor relief. Of these, 2,809 were returned as capable of training and employment. The evidence before the Committee from Poor Law returns and the figures furnished by certain organizations indicates that there are probably not less than 10,000 incapable blind persons in the United Kingdom.

A comparison of the census returns of 1901 and 1911 indicates that though the total number of blind has increased, the proportion of blind to the population has diminished, except in Ireland. The exception is explained by Dr. Coey Bigger, of the Local Government Board for Ireland, as probably due to the effects of emigration leaving a residuum of blind persons out of proportion to the rest of the population.

Age Incidence and Causes of Blindness.

The data on age incidence are meagre. The returns of the census indicate that the three main causes of blindness (the last is the heaviest) are: (1) Accidents; (2) congenital and infantile diseases; (3) cataract, optic neuritis, or other eye trouble.

Comment is made on the part played by ophthalmia neonatorum in the production of infantile blindness. It is held to account for 10 per cent. of the total of blindness at all ages. Some evidence was taken on the measures in vogue for the prevention of the disease and for the better securing of the full effects of these measures. That a very high standard can and should be obtained is manifest, and it is equally clear that there is room for improvement in not a few parts of the country. Prompt notification of the disease is needed, and efficient nursing for "the treatment of a child with ophthalmia neonatorum means treatment nearly all day and a good part of the night." It is essential that hospital accommodation should be provided for the child (and if necessary for the mother also) in a certain number of cases. The disease is more prevalent in squalid homes, where efficient treatment cannot be secured, than in those where better conditions prevail. Comment is made on the large number of cases of blindness due to interstitial keratitis consequent on inherited syphilis. The report quotes the Royal Commission on Venereal Diseases as coming to the conclusion (par. 102) "that over 50 per cent. of all blindness was due to venereal diseases." This is a misquotation; the words of the report of the Royal Commission are: "The figures laid before us by Mr. Bishop Harman show that more than half of all cases of blindness amongst children are the result of venereal disease in the parents."

Under the heading of "Occupational Blindness" attention

¹ H. M. Stationery Office, London, 1917. (Cd. 8655.) To be purchased through any bookseller, price 9d. net.

is called to the need for more care for the protection of the eyes of workpeople engaged in hazardous occupation.

It appears that, with the exception of the bottling of aerated waters, in no industry are the employers compelled to provide, or the workpeople to wear, goggles; and, further, where goggles are provided (and such places are few) workmen will not wear them, partly because sufficient attention has not been given to the production of comfortable goggles, and partly because of sheer prejudice on the part of the worker; . . . 5 per cent. of all accidents reported by the certifying surgeons in factories and workshops for the years 1907-14 are eye injuries; and of these, 2.5 per cent. at least result in the loss of one or both eyes.

Education.

The effect of the Elementary Education (Blind and Deaf Children) Act of 1893 for England and Wales has been admirable, and Scotland is equally well provided for. There is no such provision for Ireland, and the Committee report that a system of compulsory education, on the line of the Act of 1893, accompanied by State inspection and State grants, should be set up in Ireland. The endless controversy between day and residential schools crops up, and it is evident that strong opinions on either side were expressed. The report shows the effect of this diversity.

The witnesses who considered the day school as the better system laid stress on the undesirability of withdrawing children from their home life and segregating them from their sighted fellows. There is undoubtedly much weight in the latter consideration; education with sighted children obviously tends to make the blind child more normal. The majority of the witnesses were, however, strongly in favour of residential schools as providing better discipline, a more constant and skilled supervision, greater individual attention, more highly-organized games and exercises, a proper dietary and medical supervision, and greater education facilities generally.

In considering these opposed views the report gives weight to both, but in the final summary plumps wholly for the institutions or residential schools. A similar conflict of evidence arose regarding the use of sighted and blind teachers. The former have the benefit of the better discipline they can secure; but the value of the blind teacher is undoubted. As Sir Arthur Pearson pointed out in reference to the training of blinded soldiers and sailors, "the whole outlook of a man becomes different when he finds himself in the hands of a teacher who works under the same handicap as his own."

The necessity for special provision for the training of myopic children is emphasized, and praise is given to the excellent work done by London in initiating these special classes. Comment is made, also, on the necessity for extending the system of "after care" of the children who have attended blind schools. With a few notable exceptions the suggestions of the Royal Commission of 1889 have not been carried out in this respect. To secure the best effect of the education given to these children it is necessary to oversee them for at least two or three years after leaving school, to assist them to good and continuous work, otherwise difficulties daunt them, and they drift into the unoccupied ranks.

With regard to professional training, the Committee is satisfied from the evidence that there are some callings on which blind people may embark with a reasonable prospect of success: music, pianoforte tuning, the religious ministries, teaching, massage, and various forms of business work, such as typewriting and shorthand. But for each a proper aptitude and education is necessary to success.

The matter of training for industrial occupation is carefully handled, and it is pointed out that there must necessarily be a high percentage of blind persons for whom this form of occupation is alone suitable. Many forms of manual work are cited as being successfully followed, and among additional trades it is suggested that upholstery should be taught. But in all trades it is urged that success needs more than training; it requires the provision of suitable workshops where the trained blind can work successfully. For this there is the greatest need of provision, and until this need is met further facilities for training will be of little avail.

Wages.

As to the earning capacity of the blind, the Committee finds—

The value of the output of the blind worker is, in the first place, diminished by the cost of the sighted supervisor, which is absolutely necessary. In the second place, the blind worker is normally . . . not capable of attaining a speed of more than

half that of a sighted worker. As a general rule it does not appear that the earning capacity of the blind worker can be put higher than half that of a sighted worker.

As to the manner in which the poor earnings of the average blind can best be augmented to a level at which they can live, it is stated that several methods have been adopted by institutions to augment wages. Better organization of the workers is insisted upon, so that each gets the work he can earn most at. The relative values of workshops or home industries came under consideration. It was found that for the large majority the workshop was better; the home industries produce only one-half to two-thirds of the wages earned at the shops.

With regard to the large number of blind in receipt of Poor Law relief it is said:

We entirely agree that the incapable blind should be assisted by pensions rather than Poor Law relief. . . . In our opinion every incapable blind person who is worthy should be secured an adequate pension; and it will be necessary for the State to provide additional funds for this purpose.

The existing provision for pensions by various societies is set out. Some of the pensions are pittance of £5 to £6. The Committee fear these small sums are waste of money, and may stimulate the recipient to go-round cadging. This part of the report concludes with a eulogistic account of the work done by Sir Arthur Pearson for blinded soldiers and sailors.

Recommendations.

The most urgent necessity shown by the inquiry is a co-ordination of effort. To this end it is recommended that a special Government department should be created whose function shall be the general care and supervision of the blind. The department should form part of the "Ministry of Health," or, pending the establishment thereof, the Local Government Board. A scheme for the provision of 3,000 more workshop places is urgently needed, and it is recommended that a strong Advisory Committee of persons associated with the care of the blind should have the immediate guidance of the scheme.

The Committee recommend the adoption of the definition of blindness arrived at by the Ophthalmological Section of the Royal Society of Medicine: "Blindness means too blind to perform work for which eyesight is essential." Further recommendations cover a number of details regarding statistics, elementary, professional, and industrial training, the general trend of which are indicated in the foregoing summary of the report. In conclusion the Committee write: "We want to impress upon the country the extremely hopeful nature of this problem."

Reservations.

There are certain "reservations" made by members of the Committee. Mr. A. A. Allen, Sir Arthur Downes, and Mr. Thomas Stoddart comment on the weakness of the recommendation of the Committee regarding pensions. This is the more remarkable in view of the fact that the State has assumed responsibility for those blinded in the war to the extent of 27s. 6d. a week. These members recommend that the State should recognize the handicap from which blind people necessarily suffer and should make a suitable allowance to every blind person above the age of 21 who has no private means of support and is not unworthy. Another reservation by Messrs. A. A. Allen, H. W. T. Bowyear, and Sir Arthur Downes concerns elementary schools. They take exception to the general recommendation of residential schools: "It seems to us that, as in the case of sighted children, institutional life is a poor substitute for home and family life." They cite as eminently successful the system in vogue in the London County Council area of day centres for the children up to a certain age and then the provision of residential trade schools for boys and for girls. They also point out that there is another objection to drafting young blind children into institutions—"such a system would meet with opposition from many parents."

THE Alvarenga Prize of the College of Physicians of Philadelphia has been awarded for 1917 to Dr. Wilburt C. Davison of Baltimore for his essay on the superiority of inoculations with mixed triple vaccine (*B. typhosus*, *paratyphosus* A, and *paratyphosus* B) over successive inoculations with the single vaccines, as shown by agglutinin curves in men and rabbits.

THE SANATORIUM TREATMENT OF TUBERCULOSIS.

ANNUAL REPORTS.

National Hospital for Consumption, Ventnor.

In his report for the four years, 1912-15, the Senior Resident Medical Officer of the National Hospital for Consumption, Ventnor, Dr. Arthur Hawkins, opens with a detailed description of the exact daily routine which is adopted for all patients admitted to the institution.

So much of the success of treatment depends upon the strict adherence by the patient to the instructions given to him that it is very necessary for intending patients and for the medical advisers to know exactly what those instructions are. At first sight the rules and regulations in force at Ventnor would seem somewhat alarming. Every moment of the patient's day is mapped out for him. But among the first of these rules is one which obliges him to attend a lecture on his first Saturday afternoon, in the course of which he is made to understand the *rationale* of the system and the advisability, for his own sake, of cordial co-operation.

The scale of diet at Ventnor is not framed with any idea of over-alimentation, but it appears to be sufficient, and the average gain of body weight is satisfactory. Special attention is paid to mastication of food, and full time is allowed for the purpose. The vital importance of this point is too often forgotten, but the relation of dental hygiene to digestion has of late years been more fully recognized, both in military and in civil practice.

The introduction of graduated manual labour, both indoor and outdoor, is being proceeded with steadily, and the general results of treatment are being maintained at a fair level. A system of after-reporting has been introduced by means of prepaid reply forms, and much valuable information as to the duration of improvement is being accumulated. It has to be noted that the number of cases admitted in the later stages of disease is still very high. The percentage of improvement amounts to 65, as compared with 91 per cent. for cases in the early stages, but it is probable that such improvement in the one case is only temporary, while in the other the patient may have been restored to usefulness. The resources of the Ventnor Hospital would be capable of dealing with a much larger proportion of curable disease if the admission of cases for which only temporary amelioration can be afforded were rigidly curtailed.

Hertfordshire.

In Hertfordshire the work of detection and treatment of tuberculosis has been vigorously pursued, although hampered in its progress by economic causes which are not at present remediable. Dr. Hyslop Thomson, the Medical Officer of Health and Tuberculosis Officer for Hertford, calls special attention in his report to the need for extension of domiciliary treatment and for loyal co-operation between the local practitioners and the special officials. Personal qualities play so large a part in the introduction of regular visitation and home treatment that it must of necessity be most successful where tact and sympathy are most in evidence. It is satisfactory to learn that provision is about to be made for the treatment of advanced cases in a county hospital and that an industrial sanatorium is also to be set up. The introduction of definite employment as a part of institutional treatment is so important a factor that it is to be hoped that it may become universal. The melancholy spectacle of fairly able-bodied men and women loafing about the wards, corridors, or grounds of large hospitals for sheer lack of employment of any kind, is only too familiar. Active work, within the physical powers of both sexes, must of necessity be advantageous, and if at the same time it can be made to pay its way, the working patients would be enabled to continue their treatment until the activity of disease had subsided, instead of returning, as they do at present, to the unhealthy surroundings from which they came, before their health is fully restored.

Newcastle-upon-Tyne.

The influence of the war upon the death-rate from consumption is the principal theme of the Medical Officer of Health for Newcastle-upon-Tyne, Dr. H. Kerr. The rate has steadily increased during the last three years, and it is disressing to note that the chief sufferers have

been among young girls from 15 to 20 who have so nobly been filling the gaps in factories, shops and offices, and in many heavy outdoor employments.

Overcrowding in dwelling-houses and overstrain, both mental and physical, would seem to be the chief factors in the general rise of mortality. The many other contributory causes, although constantly present, do not appear to have been more than usually effective, and some of them, notably alcoholism, have been far less so.

British Guiana.

An interesting report, not differing in form from the usual home type, reaches us from a far-away part of the British empire. The Society for the Treatment and Prevention of Consumption in British Guiana has been established for the last ten years, and its record of activity will compare well with that of similar organizations nearer home. The population of the colony is very mixed, but all races appear to recognize the usefulness of the society as a means of seeking out and dealing with the disease, which has hitherto caused a high death-rate, more especially in Georgetown.

A central dispensary, a public hospital, and an almshouse have provided the means for dealing with the different stages of the disease, and the steady work of lady visitors has been effective in persuading suspected cases to come up for examination. The large proportion of non-tuberculous cases would seem to indicate that their efforts have been appreciated. The death-rate in the colony is still high, more especially among female patients.

A MINISTRY OF HEALTH.

CONFERENCE OF SANITARY AUTHORITIES.

A CONFERENCE of sanitary authorities, called by the National Association for the Prevention of Infant Mortality, was held at the Mansion House, London, on October 29th, to consider the proposals relating to a Ministry of Health. Representatives attended from a large number of municipalities in England and Wales and Scotland, and were welcomed by the Lord Mayor.

Mr. NEVILLE CHAMBERLAIN took the chair, and presided for the greater part of the day. The war, he said, had shown how greatly the power, and even the very existence, of the nation depended upon the quality of its manhood and womanhood. Those who had had access to the statistics of medical classification of males of military age must have been shocked by the very large proportion of young men who failed to reach the standard of military fitness. While a Ministry of Health would not cure all the ills that flesh is heir to, it was obvious that the present division of public health administration among a number of different departments did not make for efficiency. He instanced four respects in which progress in the health services might be furthered: (1) The establishment by local authorities of their own service of midwives, who should be allowed to take pupils; (2) the appointment of doctors—perhaps preferably women doctors—specially for midwifery cases, at a suitable salary and in such numbers as might be necessary for the needs of the neighbourhood; (3) the provision of better medical attendance and treatment for young children, including sufficient hospital and convalescent home accommodation; (4) greater public control of milk and patent foods. Mr. Chamberlain also suggested that, seeing that medical officers of health were vital to all schemes of the kind, they should be selected from the best talent available, and paid a higher salary than was generally the case at present, though with the higher salary should go a stiffening of the preliminary training.

Mr. S. ROBERTS (chairman of the Sheffield Health Committee) moved, and Dr. E. W. HOPE (Medical Officer of Health, Liverpool) seconded:

That this Conference urges the establishment of a Ministry of Health.

Both speakers laid emphasis upon the difficulties and delays arising out of the present distribution of health administration among a number of Government departments.

Sir WILLIAM CHANCE declined to support the resolution. He held that there was too much inclination to call for new ministries as a solution of problems when all that was

wanting was a strengthening of existing machinery. The Local Government Board had done magnificent health work, and he was content to leave the question to that department and to existing public health authorities. He hoped that the red herring of the Poor Law work of the Board, which was an entirely separate department, would not be drawn across the track.

Sir HANER GREENWOOD held that as an immediate policy the powers of local authorities should be increased, but a Ministry of Health was an ideal that could not be realized at least for ten years. It was impracticable to proceed with the matter during the war, and afterwards it would necessitate a Royal Commission.

Dr. S. G. MOORE (Huddersfield) suggested that, without waiting for a Royal Commission, it would be possible for Ministers acting collectively to advise the King to appoint a Minister of Health, and it could then be left to that agent of the Crown to effect the co-ordination and consolidation all desired.

The following, among other medical officers of health, spoke in general support of the main resolution: Dr. JOHN ROBERTSON (Birmingham), Dr. JAMES WHEATLEY (Shrewsbury), and Dr. JAMES PATERSON (Maidenhead). The resolution was carried with three or four dissentients, and a number of addendums were put to the meeting, two of which were carried. The first of these was on the motion of Dr. T. W. N. BARLOW (Wallasey):

That the unification of control in all matters relating to the public health of the community is equally necessary locally as centrally.

The other was on the motion of Dr. HAROLD SCURFIELD (Sheffield):

That, pending the establishment of a Ministry of Health, there should be no delay in promoting legislation for the welfare of mothers and children, and particularly in extending to England the powers recently given to Scotland under the Notification of Births Act, 1915.

Councillor MARGARET ASHTON (Manchester) then moved the second of the main resolutions:

That, in view of the paramount importance of motherhood and infancy, a special department of the Ministry of Health be established to safeguard their welfare.

She called for a more united effort on the part of doctors, midwives, and local authorities to provide better conditions for motherhood. What was wanted was a real maternity benefit which could be spent on the mother herself; not a largely fictitious benefit such as the one provided for under the National Insurance scheme. She also pleaded for special care for working girls, many of whom were required to perform the duties of maternity after having been rendered unfit for such duties owing to the conditions of their occupation. No regulations with the special object of safeguarding the maternal powers of working girls and women were in force.

Alderman BENJAMIN BROADBENT (Huddersfield) seconded the resolution, although he thought that there might well be more difficulty in getting a department of maternity established within the Ministry of Health than in establishing the Ministry of Health itself. Dr. KAYE (County Medical Officer for the West Riding) and Dr. C. W. SALEEBY, both of whom urged the great necessity for ante-natal care of the mother, supported the resolution, which was carried unanimously.

Lord RHONDDA then addressed the Conference and said that his idea for a Ministry of Health was the result of his experiences at the Local Government Board when he saw the differences between the various Government departments and the occasional obstruction that resulted. Therefore it had been his ambition to co-ordinate all the health activities of the Government in one department, so that on this vital matter there would be no overlapping or friction. He had a promise from the Prime Minister that the work he had done should at least be safeguarded, and he was satisfied that the Prime Minister was as anxious to fulfil his promise as he himself was to see it fulfilled. But the Prime Minister's first duty was to maintain the unity of the nation and avoid anything likely to give rise to controversy, and thus it was necessary, before he (Lord Rhondda) could press him to fulfil his promise, that the Local Government Board and the National Health Insurance Commissioners should come to an agreement. He

urged all who were interested in the health of the country to do everything they could within the next two months to see whether some fair compromise could not be reached. A Royal Commission had been suggested, but there was no need for such an inquiry. All that was wanted was a short bill to co-ordinate the health functions of the various departments; if necessary, an inquiry could be made after the new department had been created. He added that he saw indications that some of those who had been inclined to obstruct were realizing that the Ministry of Health was an urgent matter.

After Lord Rhondda had spoken the Conference agreed to the appointment by the Association which had convened the Conference of a small committee to act in conjunction with Lord Rhondda with a view to calling together the various bodies concerned and determining whether some agreed measure could be arrived at.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on Tuesday, October 9th, nineteen cases were considered, and £176 voted to sixteen of the applicants. The following is a summary of some of the cases relieved:

Widow, aged 60, of L.R.C.P. and S.Edin. who practised at Liverpool, and died in 1894. Applicant has for some years acted as health visitor for a county council, but, owing to ill health and increasing age, will have to resign. Has recently had an operation on her foot. Income as visitor £104 per annum. The Fund promised £12 per annum when she has to give up her work.

Daughter, aged 50, of M.B.Lond. who practised at Newcastle, Staffs, and died in 1885. Applicant lost all her income through bad investments, and her health is so bad that she is unable to work. Relieved three times, £29. Voted £12 in twelve instalments.

Daughter, aged 57, of M.R.C.S.Eng. who practised at Newport, Mon., and died in 1892. Has tried to earn a living by keeping a children's school, but, owing to ill health and the high cost of living, cannot make it pay. Relieved twice, £24. Voted £12 in twelve instalments.

Widow, aged 72, of L.R.C.S.Ire. who practised in London and Wales and died in 1915. She was left entirely without means, through long illness of husband. Has two daughters, one of whom is very delicate, and the other helps all she can. Has the old age pension. Relieved twice, £26. Voted £12 in twelve instalments.

Daughter, aged 60, of M.R.C.S.Eng. who practised at Wymondham and died in 1870. Applicant is quite unable to work, and the loss of her benefactress of fourteen years left her quite destitute. Relieved nine times, £52. Voted £12 in twelve instalments.

Daughters, aged 53 and 45, of L.S.A.Lond. who practised in London and died in 1903. One is an epileptic, and the other unable to earn a living. Joint income, £69 a year. Relieved jointly nine times, £101. Voted £18 in twelve instalments.

Widow, aged 48, of M.R.C.S.Eng. who practised in London and New Zealand and died in 1901. She was left unprovided for with three young children. She has endeavoured to make a living by taking in boarders, but her house being on the Essex coast she had not been able to make it pay since the war commenced, and has had to give it up. Her eldest son has joined a cadet school, with a view to taking a commission. Relieved six times, £71. Voted £10.

Daughter, aged 56, of L.R.C.P.Lond. who practised at Birmingham and died in 1874. Endeavours to make a living by taking in lodgers, but has not been successful of late. Has only received £3 this summer. Relieved six times, £68. Voted £12 in twelve instalments.

Subscriptions may be sent to the Acting Honorary Treasurer, Dr. Samuel West, at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is now called upon, as a result of the war, to deal with many widows and children who, in happier times, would not have thought of asking for assistance. It is glad to receive secondhand clothing and household linen. The class of clothes most wanted is that suitable for boys and girls working in offices, for women, and for old men. The gifts should be sent to the secretary of the Guild, 43, Bolsover Street, W.

THE death-rate in Belgium has greatly increased in the last two years, and there has been a large decrease in the birth-rate. While the number of births in the Brussels district in 1913 was 6,417 (17 per 1,000 of the population), and the death-rate 13.7, in the first six months of 1915 the birth-rate was 14.3 and the death-rate 14 per 1,000. In the corresponding period of 1917 there were 3,311 births (8.5 per 1,000), and the death-rate had risen to 19.3.

British Medical Journal.

SATURDAY, NOVEMBER 3RD, 1917.

MEDICAL DEMOBILIZATION.

SINCE almost all the prophets have been wrong in their forecasts of the course of the war and its immediate economic effects, we may fairly suppose that prophecies as to after-war conditions will prove to be no more correct. The duration of the war is still uncertain, and the general situation at the close of hostilities can only be guessed at; but, although the future is obscure, it is a primary national duty, even at the climax of the war when victory seems the only thing that matters, to look ahead and prepare for peace. The war took us unawares, and the nation as a whole has only put itself on a war footing at a vast expenditure of time, money, and energy. Our unpreparedness for war has cost us dearly, and unless we take adequate steps in time the advent of peace may find us at an equal disadvantage. A Minister of Reconstruction has been appointed, and the Ministry of National Service is in process of reorganization upon lines which seem to be sound for the immediate purpose in view; but demobilization and the reconstruction of national life after the war will test the best brains of every department of State, and of every trade and profession. The wheels are all moving in one direction now, and the problem is to adjust the machinery whilst it is in motion so that it may stand the shock of moving in the opposite direction.

While it is our duty to make ready for peace, when it comes, the number of incalculable factors renders it impossible to draw out precise plans now. We do not know when or how the war will end, nor can we foretell the economic condition of the world when peace arrives; least of all can we conjecture what will be the attitude of the nations towards armaments and international rivalries; yet the whole circumstances of demobilization and reconstruction must depend upon the length of the war, and be governed by its moral and material results. Demobilization signifies the reduction of military forces to a peace footing, but until the end is in sight no one can say what will be the peace footing of our naval and military forces in the changed conditions after Armageddon. It is necessary to take this wide outlook in approaching any discussion of general or sectional demobilization, for otherwise there will be a danger of being captivated by concrete schemes which in the nature of things must rest on a basis of hopes and prophecies.

Having said so much, we may welcome any indications that the military and civilian medical authorities are approaching the matter in advance from a statesmanlike standpoint, before their hands are forced by the arrival of peace and the need for immediate action. Notwithstanding all the uncertainties it is high time to begin collecting information and ideas, and we are glad to know that the Central Medical War Committee has already discussed certain aspects of medical demobilization, and offered its assistance to the Army Medical Department. The way in which doctors are to be restored from the forces to civilian life needs careful thought. If, when the time comes, it is to be conducted on an orderly, rapid, and equitable plan, with due regard to economy, co-operation will be

needed beforehand between the naval and military authorities, various Government departments and public bodies, on the one hand, and the statutory professional committees, whose duty it has been to find civilian doctors for the army while safeguarding the medical needs of the public at home, on the other.

The process of drafting medical officers out of the army after the declaration of peace is one in which the War Office will, we have no doubt, be ready to have the guidance and help of civilian medical authorities. Military considerations will determine the numbers that can be dispensed with, and the rate at which the outgoing stream should flow; beyond this the problem is far more civilian than military in nature. An adequate supply of specialist services will have to be maintained in the army during demobilization; otherwise, the principles upon which individual medical officers are selected for release, and the order in which they are released, must be determined mainly by reference to civilian needs, of which the army is not in a good position to judge, and to individual circumstances, of which the statutory professional bodies are the best judge.

Any scheme for demobilization of individual medical officers, however provisional, will naturally take into consideration such factors as age, health, and physique; professional circumstances and domestic obligations; and length and kind of military service. The kind of service is of great importance, and no scheme will do justice all round which fails to reckon with this factor. Whatever plan is devised there are sure to be hard cases, but everything possible should be done during demobilization to remedy existing grievances by smoothing the homeward path of those whose terms of service have been the hardest. An equitable basis of selection would thus take into special account the case of the Territorial and Special Reserve officers, who have served since the first days of the war, with no prospect of release, and with disabilities in respect of pay, gratuity, and promotion, which are familiar to our readers. No military technicalities should be allowed to retain these men a day longer than is strictly necessary. The circumstances of temporarily commissioned officers vary widely; some who have served for two or three years, or longer, are now, if of military age, not much better off than their Territorial and Special Reserve colleagues—since their contracts are no longer annually renewable. Other things being equal, it would seem fair that those who have served longest should be liberated first; and of these the senior men nearing the upper limit of military age, with strong professional claims on public or private grounds, would have a *prima facie* case for early demobilization—almost as strong as those in like circumstances but above military age. Discrimination will be a delicate task, because the Military Service Acts altered the whole situation. With regard to newly qualified men the matter should be rather less difficult; it would seem to be both fair and politic that these should be withdrawn from the army last, and that medical students who have been allowed to continue their studies should, on joining the profession, become automatically available for the medical services of the army during the process of demobilization, and for a certain period afterwards if needed to maintain the officer strength of the R.A.M.C. and the Navy Medical Service. This would do something to equalize matters as between students who have had preferential treatment under the Medical Service Acts and those who, serving as combatants, have fallen behind in the race of life. The latter have a strong case for special

consideration, and if it is inexpedient to return them all now to their studies they ought in justice to have every opportunity for making up lost ground as soon as the war is over.

These few preliminary observations will have served their purpose if they indicate some of the lines along which the problem of medical demobilization is being approached, and thus stimulate discussion within that large section of the profession which will be directly affected by the method chosen for returning doctors to civil life at the end of hostilities.

SPIROCHAETOSIS ICTERO- HAEMORRHAGICA.

As an example of the value of what may be called "team work," in establishing an accurate explanation and view of the clinical course of a disease and its prophylaxis, attention may well be directed to the series of papers¹ recently published from the First Medical Clinic of the Imperial University in Kyushu, Fukuoka, Japan. In 1915 a disease in Japan, resembling that known as Weil's disease and formerly ascribed to infection with *Bacillus proteus fluorescens*, was proved by some of these workers to be due to the *Spirochaeta icterohaemorrhagiae*, and this advance was subsequently confirmed on the Western front. The disease has therefore been called spirochaetal jaundice (icterohaemorrhagic), and it has been further shown by British observers (Stokes, Ryle, and Tytler²; Hume and Dawson³) that this spirochaetosis though usually is not invariably accompanied by jaundice. In one of the recent Japanese contributions the view that house and wild rats and field mice act as carriers is confirmed, the spirochaete being present in the kidneys and urine only and not in the blood—a condition resembling that in human convalescents from the disease. The escape of these urine-borne spirochaetes into the soil of damp mines and trenches facilitates infection through the skin, especially in barefooted miners. Further, the curves of the incidence of rat and human infection correspond. Stimulated by the knowledge that the cholera spirillum and other bacteria and protozoa do not thrive in an acid soil, Ido, Hoki, Ito, and Wani found that the spirochaete dies in a weakly acid medium and that the disease is rare in the parts of the province of Fukuoka with an acid soil, whereas it is endemic in those with an alkaline or neutral soil.

Two other papers, that by Kaneko and Okuda on the distribution of the *Spirochaeta icterohaemorrhagiae* in the human body, based on forty-three necropsies, and that on the clinical aspects of the disease by Inada, considerably modify our existing views, first by dividing the course of the disease into three stages in correspondence with characteristic features as regards the presence or absence of spirochaetes and their antibodies in the blood, the urinary excretion of the spirochaetes, and their distribution in the organs of the body; and, secondly, by throwing doubt on the assumption that the second attack of fever observed in 28 per cent. of the cases is a true relapse of the disease. The first or febrile stage, during which spirochaetes are present in the blood and in the main extracellularly in the liver, adrenals, and kidneys, lasts about a week, and on the fifth day the formation of antibodies begins. In the second or icteric stage, also lasting a week, in which jaundice is

at its height and the mortality is highest, the spirochaetolytic and spirochaeticidal antibodies destroy the spirochaetes in the blood in the liver and adrenals, where irregular degenerated relics only are visible. The blood thus becomes free from spirochaetes, which, however, persist in the heart muscle and kidneys, chiefly inside the cells. In the third or convalescent stage, beginning about the thirteenth day, the jaundice subsides, anaemia and emaciation appear, the antibodies are fully developed, the urinary excretion of spirochaetes, which occurs to some extent during the earlier stages, reaches its maximum and may continue till the fortieth day of the disease, and the spirochaetes have disappeared from the organs of the body, except the kidneys, where they are always present, and do not seem to be affected by the antibodies. During convalescence there may, after an afebrile interval of two to ten days, be a second period of fever lasting from four to twenty days, and usually spoken of as a "relapse," but Inada points out that the symptoms are those of fever only and not a repetition of those seen in the primary attack, that spirochaetes are absent from the blood and organs except the kidneys, and that the antibodies are fully developed. This "after fever" is regarded as a reaction on the part of the body to the resorption of spirochaetal poisons; but, as it is not clear why it occurs in a proportion only of the cases, more information as to its nature is required.

A further point of interest brought out in two more papers by the same team of investigators is the comparison between spirochaetosis icterohaemorrhagica and rat-bite fever, which is now known to be a spirochaetosis and not, as was formerly thought, a sporozoa or a streptothrix infection. In rat-bite fever the serum of convalescents contains an antibody which destroys the causal spirochaetes, but is much weaker than the antibodies in spirochaetosis icterohaemorrhagica. As a result the immunity conferred is not complete, and recurrences may take place yearly for ten or even for fifteen years (Kitagawa and Mukoyama).⁴

A FRENCH VIEW OF THE DECLINING BIRTH-RATE.

THE French Academy of Medicine received nearly six months ago from a special committee a report, drawn up by Professor Charles Richet, on the depopulation of France. It has been discussing this report and another by Professor Pinard in its own leisurely fashion ever since, but has not as yet formulated its final conclusions. Professor Richet's report is lucid, eloquent, and courageous, as we expect everything from his pen to be, and it will be worth while to trace the general lines of his argument.

He started on a pessimistic note; the number of births in France, he said, is diminishing with the constancy and precision of the regular parabola described by a stone falling to the earth. There were over a million births in 1876 and less than three-quarters of a million in 1913. The birth-rate fell from 210 per 10,000 inhabitants in 1901 to 172 in 1911; though the rate of mortality has diminished, the excess of births over deaths grows smaller, and in one year, 1911, the deaths were 34,869 in excess of the births. The birth-rate, as is well known, has been falling pretty steadily for about half a century in all the countries of the western civilization, but the fall began earlier in France than in the others, and has been steadier. Comparing the ten years 1841-50

⁴ Kitagawa and Mukoyama, *Arch. Int. Med.*, Chicago, 1917, xx, 317.

with the ten years 1901-10 and taking the rate in the earlier period as 100 in the several countries, the fall was, according to the figures used by Professor Richet, in France to 74, in England and Sweden to 84, in Austria to 89, and in Germany to 92; comparing the periods 1871-80 and 1901-10, the birth-rate in France per 10,000 inhabitants fell from 254 to 206, in Sweden from 305 to 258, in England from 354 to 272, in Germany from 391 to 329, and in Austria from 390 to 347.

Professor Richet then examined in succession the various explanations suggested to account for the fall of the birth-rate in France, and we may follow him, for though his facts and conclusions apply only to France, they are of value to us if only as destructive criticism of some favourite theories.

One suggestion of a cause more or less peculiar to France is the provision of the law compelling the division of property, land and houses, between a man's children. Professor Richet considered that though this cause might be assumed to have some effect, its influence had been greatly exaggerated; his main argument is that though the law dates from 1801 the fall of the birth-rate has been more rapid than ever since 1878, and that it has taken place not only among peasants directly affected by the legal provision as to the partition of property, but also among the workmen who have no property to bequeath. He considered, further, that little weight can be attached to increased indifference to the injunctions of the Church; he admitted that in certain districts, as in Brittany, where the religious sentiment is strong, the birth-rate is high, but he pointed to others, equally religious, where it is very low. He was equally disinclined to attach much weight to the theory which would attribute any great influence to migration from country to town, for in France the birth-rate in rural districts is diminishing as rapidly as in the towns, and he quotes several instances of regions in which it is higher in the industrial parts than in the rural; but he appeared to admit that as it is chiefly the young who migrate, the migration must have some effect. With regard to alcoholism, he held that its effect is rather to cause a deterioration in the physique of children than to diminish their number, and points to certain districts in which, though alcoholism is rare, the birth-rate is low. It seems to us a defect in Professor Richet's report that he did not examine fully the influence of venereal diseases on sterility and infecundity. He included it among the causes of complete sterility in the 15 per cent. of sterile marriages, but made only a passing and not very lucid reference to the effect of venereal disease contracted after marriage in preventing the birth of more children after the first one or two.

It was estimated that in 1911 there were in France 11,696,663 families. Of these, 14.6 per cent. had no children living, 25.7 per cent. had one child living, 23 per cent. had two, 13 per cent. had three, 7.5 per cent. four, 6.8 per cent. five or six, and 2.8 per cent. seven or more. Nearly a million families were not accounted for, but assuming the distribution to be the same in them it would appear that half the families in France have only one or two living children, and that only a third at most have more than three. Remembering that nearly a sixth of the families have no children it is not surprising that even before the war the population had become almost stationary, and included a large proportion of old persons.

Some years ago Richet and Pinard came to the conclusion, from the examination of the statistics of

Berlin, Paris, Scotland, and Rio de Janeiro, that the proportion of sterile marriages in these communities, so different in manners, social condition, and race, and experiencing such varied climates, was 15 per cent.—practically the same as in the whole of France. Of the 85 per cent. of marriages remaining, they allowed that 35 per cent. might be infecund owing to physiological, or rather pathological, reasons. Professor Richet argues that the remaining 50 per cent. of marriages ought to result in large families. Taking the average age at marriage for a woman in France as 22 years, he assumes that she might have a child every second year up to the age of 44, so that families of ten children should be common. His general conclusion is that the cause of the decline in the birth-rate in France is to be found in deliberate and voluntary restriction of families, due only in small degree to the practice of abortion. Dr. Louis Parkes, as was shown in an article published in our columns on April 1st, 1916, arrived at much the same conclusion, and pointed out that it applied not only to Great Britain but to all the more highly civilized and industrial nations. He attributed the decline to a desire for a higher standard of social comfort, disinclination of women to give so much of their lives and energies to the rearing of the future race, and their desire for a larger share in the political and other privileges enjoyed by men, combined in the case of both parents with a doubt as to what the future may have in store for the offspring. Professor Richet attaches most weight to the actual cost of rearing a child; he estimates that in the working classes a child, up to the age of 15 years, costs every year a sixth of the father's earnings, and the main conclusion he recommended the Academy to adopt was that the only remedy is for the State to make an equivalent contribution to the family budget, payable to the mother; it seems probable that a recommendation in this sense will be made.

MILITARY HOSPITALS IN INDIA.

SIR GEORGE MAKINS, President of the Royal College of Surgeons, who for the last three years has been consulting surgeon with the British Expeditionary Force in France, has been appointed chairman of a committee instructed to report on the organization and equipment of hospitals for British troops in India. Both the Royal Army Medical Corps and the Indian Medical Service are represented on the Committee, and the inquiry will be conducted in India. It is hoped not only that the Committee will report early but that there will be no undue delay on the part of the Government of India in acting upon its recommendations. The ground has already been cleared and the points at issue narrowed down by the labours of two recent committees. The last, in 1913, was hampered by the instruction that no recommendation made should involve any increased expenditure, and it is, we believe, a fact that all previous attempts during the last quarter of a century to bring stationary or cantonment hospitals for British troops in India up to date, have been impeded by the opposition of the finance department of the Government of India. In spite of this adverse circumstance, the Committee of 1913, which was presided over by Sir Arthur Sloggett, then Director of Military Medical Services in India, made certain recommendations, not all of which, however, were carried out by the Government of India. Some of the evidence given before the Mesopotamia Commission condemned existing arrangements very strongly. Sir Alfred Keogh, for instance, speaking, he said, with a full sense of responsibility, asserted that the medical arrangements connected with the army in India had been for years most disgraceful, and Surgeon-General

MacNeece, then Director of Military Medical Services in India, said of the hospitals for British troops, "even now there are practically not more than two or three up-to-date military hospitals in India." The Commission recommended that there should be an immediate and general improvement in the whole standard of comfort and accommodation in the hospitals for British troops in India, and added that it was discreditable to the Indian Government that the general standard of hospitals in India should fall below the standard and efficiency now demanded in military hospitals at home. The new committee has been instructed to report only on hospitals for British troops in India, but Sir Havelock Charles described the sepy hospitals in India as a disgrace to the Government of India, and Sir William Babbie said that they were so bad that he thought it would be necessary to reform them *ab initio*. The Mesopotamia Commission advised that no time should be lost in substituting a station hospital system for the present regimental treatment of Indian troops. Time has already been lost, and we cannot hear that the Government of India is displaying any anxiety to introduce the reforms long overdue. The general impression of those who know the ways of the Government of India is that the delay is solely due to the opposition of the finance department, which fears that any improvement will involve increased expenditure. The finance member of the Governor-General's Council, in presenting his budget after eight months of war, boasted that "our chief economy occurs under the military services." The Mesopotamia Commission admitted that it was the primary duty of every well regulated government to enforce effective economy, that is to say, to prevent waste and yet ensure efficiency; but it went on to observe that "economists, when in office, not unfrequently found themselves, in defence of their principles, obliged to subordinate efficiency to economy, by adopting the simple process of cutting down aggregates of expenditure, or, at any rate, of refusing an increase of existing outlay, no matter what may be the urgency of the fresh demand." So long ago as 1911 Sir Douglas Haig, then Chief of the Staff in India, put in a memorandum on the need for giving the Indian army modern equipment in all branches, and Sir O'Moore Creagh, who was Commander-in-Chief down to April, 1914, stated that he was constantly calling attention to the deficiency of the Indian army as regards modern equipment in various respects, including transport and medical complements. He was overridden by the finance department, and it would not be surprising to learn that it was again the finance department which is standing in the way of improvements in the methods of treating Indian soldiers. Eloquent tributes were paid in both Houses of Parliament last Monday to the gallantry with which Indian troops helped to hold the line in Flanders in 1914 and to their services in Mesopotamia, Egypt, and Africa. This is very right and just, but it does not relieve the home Government of its responsibility for the continued neglect to provide proper treatment for sick and wounded Indian soldiers. The Mesopotamia Commission found that the home Government agreed with the Indian Government in limiting the military preparations of India before the war in the interests of retrenchment, although the finances of India were at that time in a most prosperous state. Public opinion in this country is outraged by the inference that Indian soldiers are to suffer death by disease and wounds in order to provide the Finance Minister with a larger surplus. But whatever the extent of the responsibility of the home Government, the main responsibility rests upon the Government of India; its duty is clear, and we may well hope that the objections of the finance department will at last be overridden by the Viceroy and the Secretary of State, whose mission to India may, we hope, be productive of good results alike for the Indian soldier and the British soldier in India.

THE WELFARE OF THE BLIND.

The President of the Local Government Board has promised that effect shall be given to the main recommendations of the Departmental Committee on the Welfare of the Blind, which are the establishment of a special department for the general care and supervision of the blind, the provision of a capital sum for the establishment of workshops, and an annual vote out of which grants could be made. The Committee regards the problem as hopeful, pointing out that there has been a steady decline in the proportion of blind to the population, and that there is reason to expect that, apart from the effect of the war, the proportion can and will by degrees be permanently diminished, but it insists on the necessity for central control, organization, and assistance for the existing agencies of voluntary help. We publish elsewhere in this issue a summary of the facts upon which the Committee based its recommendations and conclusions. From it it will be seen that the main difficulty of the blind is industrial. Most of the blind can work, but with rare exceptions they work under a heavy handicap; their skill is often less, and their speed is much less, than that of a sighted worker; their average earning power is one-half that of the sighted man. The recommendation for the establishment of workshops will meet with general approval. But how best to make up the poor earnings of the blind to a living wage is a problem which has been left unsolved by the Committee. It is difficult to steer a clear course between help that fosters self-reliance and help that smother's initiative and only awakens a hunger for more help. Three members of the Committee make important reservations: they contrast the obligation undertaken by the State for those blinded in the war with the absence of recognition of obligation for the rest of the blind. They think "the better course would be for the State to recognize the handicap which blind persons suffer, and to make suitable allowance to all blind persons above the age of 21 who are not unworthy of assistance and who have not sufficient private means of support. If a system of general pensions for the blind were to be adopted, it would be necessary for the central authority to be satisfied that the blind person was doing his best to contribute to his own support and to have power to withhold a pension if the blind person refused training or suitable employment, or took to street begging, or was convicted of crime or drunkenness. Strictly speaking, the terms of reference of the Committee did not cover inquiry into the causes and prevention of blindness; but it took some evidence thereon, and in this it has been scarcely happy. The witnesses called were very few, and only one was an ophthalmic surgeon. On many important points the evidence displayed a scarcely excusable ignorance of municipal administration, and this has led to comments in the report which are inaccurate. Certain municipalities are complimented upon the excellence of their arrangements for the care of the notified cases, but London is damned with faint praise. It would appear that the Committee did not know what London is doing for the care of these cases; it might have obtained the information from the reports of the Medical Officer of Health for the London County Council for the last six years, or from the recent report of the Central Council for District Nursing in London. This lack of care extends even to the matter of quotations from official reports and blue books. For example, it is stated that in one year (1913) in Birmingham "in only one case was the sight lost" from ophthalmia neonatorum. When the report of the medical officer of health of this city is examined it is found that the case so returned was "blind in one eye," but there were three cases of "complete blindness" and "five of large corneal opacities." Again, on the larger question of the influence of venereal disease on the production of blindness, the Committee quotes the Royal Commission on Venereal Disease as finding that "over 50 per cent. of all blindness was due to venereal diseases," whereas reference to the cited paragraph of the Royal

Commission's report shows that the statement is made in regard to blindness amongst children only. Such errors of quotation are blemishes on a report issued from the Government department which has more to do with public health than any other; they are liable to cause serious misapprehensions. It is not unlikely that the erroneous statement that 50 per cent. of all blindness is due to venereal disease may be used by persons who do not trouble to verify their references, to make a mischievous and unwarranted reflection upon the blind.

RURAL HOUSING.

THE housing of the working classes is an economic problem the solution of which has taxed the wit of social reformers for many years past. It is a problem so bound up with other important issues, such as the rate of wages and the tenure of land, that it is not surprising to find it still unsolved. Whether conditions existing in pre-war days, and to a large extent at the present time, will in the coming years be so modified as to render the task of dealing with the problem easier it is impossible to foretell. It is perhaps tolerably certain that in country districts the wages of the labourer will be increased, so that he may be in a better position than formerly to pay what has been described as an "economic rent." On the other hand, if the cost of building is increased *pari passu*, so that with an increase of wages there is a corresponding increase in house rent, no progress will have been made. In many urban districts the pressure of public opinion has been sufficient to compel the authorities to admit that they have obligations in this matter, though it may not often have been adequate to ensure their fulfilment. In rural areas matters have not got even so far as this, for there public opinion can, as a rule, only find imperfect expression. The rural district council is the local authority responsible for the proper housing of the inhabitants of the district, and it usually consists of farmers and other employers, who would have to pay most of the increase in the rates a forward housing policy would entail. A great deal of hesitation has been shown in the past by many of these rural councils in improving housing conditions. It is, perhaps, safe to predict that that hesitation will not be so pronounced in the future. A broader and more enlightened view must of necessity be taken. One of the greatest lessons to be learnt from the war is the need of stalwart and vigorous British men and women. In the past three years, and especially in the past two, mighty efforts have been made to raise the physical standard of recruits, and it is marvellous to see the improvement that has resulted even in a few months from regular habits, good feeding, and proper housing. Category C men have become fit in this way for category B, and B men for A. The aim of all thoughtful men should be that every man, woman, and child in the British empire should be living under such conditions as will ensure that he or she is normally in category A. This result might possibly be attained in England if those members of rural district councils who have in the past obstructed housing schemes not only ceased obstructing but assisted in bringing such schemes to a successful issue. A very common reason alleged for the paucity of building enterprises in rural districts is the necessity for complying with building by-laws. It is true this excuse is not heard so frequently as at one time, for in many districts its plausibility has disappeared owing to the success of the work of the Building By-laws Reform Association, which during its short existence—it was dissolved in 1912—drew up a set of by-laws for rural districts to replace those which had previously done duty for urban as well as rural districts. About the same time the Local Government Board put forward a new series of model by-laws for rural areas to which little or no exception could be taken provided they were administered in a proper spirit. Though this is not always the case, the first step for every reformer to take is

to secure the adoption of these modified by-laws in rural districts and their equitable administration. From reports of recent discussions at meetings of rural district councils it appears that there are still some members of these bodies who argue against the adoption of by-laws on the ground that a house having been erected on lines opposed to present-day views of a healthy residence the district council possessed ample powers to secure the closing of the dwelling. A very slight experience of the past actions of these bodies is sufficient to convince an inquirer that no steps would be taken to close such a house, and that if every builder were left free to set up for himself a standard of a sanitary dwelling little or no advance would be made in securing better habitations.

TREATMENT OF HAEMOTHORAX BY ARTIFICIAL RESPIRATION.

Hess¹ gives an account of the method of treating early cases of haemothorax by artificial pneumothorax. He contrasts the conservative treatment he followed in the earlier part of the war with the more active treatment he has now adopted in the field. He points out as defects in the earlier treatment of leaving the fluid untouched, the following facts: (1) The patient must remain for a long period in bed, as even sterile effusions of blood take much longer to absorb than ordinary pleuritic effusions. (2) Infection of the haemothorax fluid is very common. Hess has therefore recommended, since the beginning of 1916, early withdrawal of the fluid by puncture, followed by the introduction of nitrogen or of air under controlled pressure. He describes his technique, the chief point of which appears to be that after withdrawing 50 c.cm. of fluid by suction, double the volume (that is, 100 c.cm.) of the gas is slowly blown in, so as to keep up a positive pressure and collapse the lung. Thereafter 100 to 200 c.cm. of fluid are withdrawn, and double the volume of gas blown in to replace it. This quantity is removed again and again, and replaced by the gas, until no more fluid will flow. The lung, he says, may be kept collapsed for as many days as appears necessary, by the reintroduction of nitrogen or air by means of puncture.

THE ETIOLOGY OF PELLAGRA.

In Bulletin No. 106 of the Hygienic Laboratory of the United States Public Health Service appear some very important studies on pellagra. In the first, on tissue alteration in malnutrition and pellagra, Dr. Sundall comes to the conclusion that from a pathological standpoint there can be no objection to the classification of pellagra along with rickets, scurvy, and beri-beri as dietary diseases; that no organisms which can be regarded as specific etiological factors have been found in the tissues, while the pathological changes show no characteristic cell alterations apart from those resulting from malnutrition, and that the degenerations that occur in the nervous system, both in a series of badly fed animals and in pellagrins, are similar, and readily explained by the exhaustion theory of Edinger, Meyers, and others. In the second paper Dr. Francis relates cultivation experiments with the blood and spinal fluid of pellagrins. He states that the results were negative; the cultures either remained sterile or an occasional tube showed a growth which was evidently a contamination. His extensive feeding and inoculation experiments also were negative. "Of the 94 animals reported upon, 54 are living and 40 are dead; 18 of the latter died of tuberculosis; 10 died of acute peritonitis following peritoneal injections; 2 died of cerebral abscess following cerebral injection; 1 died of oesophagostomum; 1 female died in labour; while 8 died from causes which could not be determined at the autopsy." The survivors, with one exception, showed no indications even suggesting pellagra. Dr. Francis's work thus furnishes no support for the view that pellagra is

¹ *Munch. med. Wochenschr.*, July 1st, 1917.

an infectious disease; these very accurate and exhaustive studies would seem to indicate a deficiency origin akin to that of scurvy, beri-beri, and rickets.

A FATEFUL OPERATION.

Much has been heard lately of the evils of secret diplomacy. It does not lie within our province to discuss the general subject, but there is a closely analogous problem with which doctors are from time to time confronted. The health of rulers is a matter of direct concern to those whom they govern, but although the people may claim to know the truth if the life of the head of the State is in danger it is not always expedient that the whole truth should be known. A striking illustration of this general principle is given by Professor W. W. Keen, the eminent American surgeon, in the Philadelphia *Saturday Evening Post* of September 22nd, where he tells the story of a serious operation performed on President Cleveland in 1893. It was a time of world-wide financial crisis, when, owing to the spread of what Dr. Keen calls the "silver heresy," the life of the President stood between his country and national disaster. Had the gravity of the operation performed on him been known at the time the "panic would have become a rout." As it was, an early account of it by an enterprising journalist created acute excitement, which was only allayed by the appearance of Mr. Cleveland on several public occasions. There was no visible evidence of the operation, his voice was unaltered, and his general health was as good as could be expected in a man who had to bear the burden of his position at a time of great anxiety. Mr. Cleveland's inauguration had taken place on March 4th, and on June 18th his professional advisers found in his mouth an ulcer encroaching slightly on the soft palate. It had first been noticed a few weeks previously. There were no enlarged glands perceptible, but the condition was diagnosed as malignant. Dr. Joseph D. Bryant of New York, long the President's attendant and his intimate friend, recommended removal. Mr. Cleveland was strongly opposed to publicity, as he feared the effect of it on the people and on the financial situation. To ensure secrecy, therefore, it was arranged that the operation should be done on board Commodore E. C. Benedict's yacht, the *Oneida*. It was fixed for July 1st, and the evening before Dr. Keen, who had been called in consultation, Dr. E. G. Janeway of New York, Dr. R. M. O'Reilly, afterwards Surgeon-General of the United States Army, Dr. Bryant, his assistant, Dr. John F. Erdmann, now a well-known surgeon of New York, and Dr. Ferdinand Hasbrouck, a dentist, went on board. The living rooms of the yacht had been prepared and disinfected, and an operating table and all necessary instruments, drugs, and dressings sent on board. The President was 56 years of age, very corpulent, with a short thick neck, and the doctors were anxious about the anæsthetic. Dr. Hasbrouck first extracted the two left upper bicuspid teeth under nitrous oxide. Dr. Bryant performed the operation, assisted by Drs. Keen and Erdmann. The incisions in the roof of the mouth were made under nitrous oxide; ether was then given by Dr. O'Reilly. The whole of the left upper jaw was removed from the first bicuspid teeth to just beyond the last molar and nearly up to the middle line. The floor of the orbit had not yet been attacked, but a small portion of the soft palate was removed. This extensive operation was thought necessary because it was found that the antrum was partly filled by a gelatinous mass, evidently a sarcoma. This diagnosis was afterwards confirmed by Dr. W. H. Welch. The entire operation was done within the mouth, without external incision, by means of a cheek retractor brought from Paris by Dr. Keen. The retention of the floor of the orbit prevented any displacement of the eyeball. "This normal appearance of the eye, the normal voice, and especially the absence of any external scar, greatly aided in keeping the operation an entire secret." Only one blood vessel was

tied; pressure, hot water, and at one point the galvanocautery checked the bleeding. Only about six ounces of blood were lost. The President was up on July 3rd, and on July 5th he walked from the launch to his residence with little apparent effort. On July 17th Dr. Bryant removed some suspicious-looking tissue and applied the galvanocautery to the entire surface; on September 1st his notes record "All healed." Dr. Kasson C. Gibson of New York fitted the President with an artificial jaw of vulcanized rubber. With this in place his speech was excellent, and the quality of the voice was not altered. Mr. Cleveland died on June 24th, 1908, fifteen years after the operation. No recurrence of the sarcoma had taken place. Professor Keen says that now, after the lapse of nearly a quarter of a century, it is even more evident than it was at the time that Mr. Cleveland's instant decision, concurred in by his professional advisers, that the operation should be kept a profound secret, was very wise. "What the consequences would have been had it become known at once we can only surmise and shudder."

NATIONAL SERVICE MEDICAL EXAMINATIONS.

The Minister of National Service, in his address to the Medical Advisory Board on October 4th, as reported in our columns of October 13th, said that the first matter to which he hoped the Board would give attention was the preparation of a manual containing a code of standards of physical fitness for the guidance of the National Service medical boards in the examination of men coming before them, so as to ensure uniformity. This code or guide has now been completed, and a pamphlet (N.S.I. No. 3 of 1917), containing general directions for the guidance of commissioners, of deputy commissioners, and of members of medical boards, is now ready for issue. It defines the duties of commissioners of regions and of deputy commissioners, and lays down the method of examination to be followed by all National Service medical boards. The plan provides that all recruits will be seen at some stage of their examination by each member of the board. As a rule, the first examiner will take the weight, height, and chest measurement, and note the colour of the hair and eyes, and other general physical characters. The second examiner will pay attention to the physical development, testing the movements of the joints and investigating deformities; the third examiner will test the organs of special sense and the condition of the teeth and throat; the fourth examiner will examine the chest and abdomen, make inquiries as to previous illnesses, and will, if deemed necessary, examine the urine. Each examiner will initial the medical history sheet, indicating the grade for which he considers the man fitted. The final grading will be entered on the medical history sheet by the chairman, who, in case of doubt, will consult the full board and adopt the opinion of the majority; should opinions be equally divided he will have the casting vote. Notes are added on the points in the medical and physical examination to which special attention should be given; the conditions for which men should be rejected are indicated and standards of vision are set out. The importance of close co-operation between the medical and recruiting officials is insisted upon, as is also the need for great care and consideration in medical examination and re-examination, and in avoiding confusion of identity between two men. The medical boards are also instructed fully to consider any medical certificates produced by men at the examination. The grades recognized are four: Grade 1 comprises men who attain the normal standard of health and strength and are capable of enduring physical exertion suitable to their age. Minor defects, such as of the teeth and of eyesight, which can be removed or compensated by artificial means, will not be regarded as disqualifications. Men who fulfil the conditions of Grade 1 will be fit for general service in the army. In Grade 2 will be placed those who, being subject

to partial disabilities or near the maximum age, or beyond it in signs of wear, do not reach the standard of Grade 1, but are yet physically able to do vigorous work. Such men must be able, when trained, to march six miles with ease, must have fair hearing and vision, and must possess moderate muscular development. Men in this grade must be fit at once either for service at home or garrison duty abroad, and some will sooner or later become fit for general service. Men placed in Grade 3 will be those who are not suitable to undergo military training as fighting men, but will be fit for any of the auxiliary services connected with the army and fit to continue within the army the work on which they are already employed or its equivalent. This grade will also include those who are fit only for clerical and other sedentary occupations, such as tailoring and bootmaking. The chairman of the medical board, in the case of these men, will indicate whether they are fit for auxiliary service with the troops, for labour, or for sedentary occupations. The fourth grade will include all men unfit for military service.

THE AMERICAN COLLEGE OF SURGEONS.

COLONEL SIR BERKELEY MOYNIHAN, who is at present on a mission for the British Army Medical Service in America, and Colonel T. H. Goodwin, C.M.G., D.S.O., A.M.S., who went out with the Balfour Commission and has been in America since, were elected Fellows of the American College of Surgeons at the congress of surgeons of North America held last week. The College was founded at a meeting in Washington in May, 1913, with a membership of 300. At the first meeting the number had risen to 1,050, and last year it had reached 3,400. At this first meeting Sir Rickman Godlee, then President of the Royal College of Surgeons of England, read a message from the council of that College conveying its congratulations, and expressing the hope that the American college would grow and prosper, and that by its influence the ideals and standards of surgery would be maintained on a high plane and advanced. At a meeting in 1915 the College received the gift from Sir Rickman Godlee of a gavel designed and used by Lord Lister. In order to further its objects, which include matters of character and training of surgeons, the betterment of hospitals, and of teaching facilities at medical schools, and laws relating to medical practice and privilege, and also to provide itself with a permanent home in Washington, its Fellows have raised an endowment fund of £100,000. We publish this week an address given by Sir Berkeley Moynihan at the recent congress of the College. It deals in a systematic and masterly way with the nature and treatment of injuries to peripheral nerves. The subject has been much advanced during the last two years owing to the large number of gunshot injuries of nerves, but Sir Berkeley Moynihan's essay deals generally with the subject, and his conclusions are applicable to nerve injuries however sustained. His remarks on after-treatment are of especially wide application, for though it may fall to the lot of comparatively few to undertake operations for the suturing of nerves, the after-treatment is prolonged, so that cases may come under the care of general practitioners either in institutions or in private practice. His observations on the preparatory treatment before late nerve suture are also of very general interest. It will be noted that he insists on the strictest attention being paid to the relaxation and nutrition of all paralysed muscles, to the maintenance of the suppleness of all joints moved by those muscles, and to the preservation of the integrity of the skin. It must obviously be useless to attempt to restore continuity of a nerve if the muscles it supplies cannot act owing to scar tissue, contraction of the skin, or stiffness of the joint.

THE next session of the General Medical Council will begin on Tuesday, November 27th, when the President, Sir Donald MacAlister, will take the chair at 2 p.m., and give an address.

Medical Notes in Parliament.

The Vote of Thanks.

THE first four of the five clauses of the vote of thanks adopted on October 29th in both Houses of Parliament referred, the first to the Royal Navy, the second to the officers, non-commissioned officers, and men of the British armies in the field, and also to the women's medical and other services auxiliary thereto; the third to the troops from the Dominions, India, and the Crown Colonies; and the fourth to the officers and men of the Mercantile Marine. The last clause acknowledged with grateful admiration the valour and devotion of those who have offered their lives in the service of the country, and tendered sympathy to their relatives and friends in the sorrows they have sustained. The vote was moved in the House of Commons by the Prime Minister, who, in a striking speech reviewing each clause, paid special tributes to the fishermen, of whom, he said, 60 per cent. are in the naval service; to the air service; and to the medical service. Of this service he said: "When you come to the Medical Service, the men and the women, they have never shown greater courage, knowledge, and experience. Thousands of them have devoted themselves—devotion is the right word—to the curing of the wounded and the healing of the sick. Great consultants have given up princely incomes and volunteered for this service. Wounds have been cured which before the war were regarded as fatal, and I may give an illustration, and only one illustration, of the services they have rendered in saving life, not merely by their curing expedients, but by the precautions they have taken. In the South African war I believe 50,000 men died of typhoid. In France, out of our gigantic army, during the whole three years of the war, only 3,000 have fallen victims to this disease. We owe thanks to the medical profession; they have suffered, hundreds have been killed, and many more hundreds wounded. We should also thank the women, our trained and untrained nurses, whose tenderness and care for the wounded have earned thanks from the lips of hundreds of thousands of poor men whose lives have been saved, and who have been spared much suffering through their tender ministrations. They have not escaped perils. Many have been killed by shell fire, many of them drowned in hospital ships sunk with the sign of the Red Cross. We all owe them a debt of gratitude." England, he said, had contributed 75 per cent. of the army of the empire, and 75 per cent. of the loss had fallen upon England. Scotland had, as always, done its due share; Ireland had made a distinguished contribution; and Wales, he said with pride, had in voluntary recruiting just beaten the record by a shade, Scotland coming second. Mr. Lloyd George was followed by Mr. Asquith, who delivered a speech of characteristic dignity and conciseness. Next came Mr. Redmond, who said that the Irishmen who had fought need have no misgivings that they were right from the first, that time would vindicate them, and show that while fighting for civilization and liberty in Europe they were also fighting for civilization and liberty in their own land. Next, Mr. O'Grady spoke for labour; Mr. Eugene Wason for Scotland, Sir J. H. Roberts for Wales, General Croft for the New National Party, and Mr. Peto expressed the thanks of the officers of the merchant service for their inclusion in the vote. Mr. Lloyd George had referred to the great contribution of India. Colonel Yate, as an old Indian officer, pointed out that the 70,000 men in the first forces which came from India in 1914 had helped to hold the trenches until our own new army was ready. In Egypt, in Mesopotamia, in East Africa, and elsewhere, also, they had done well.

In the House of Lords Earl Curzon made a striking tribute to the effort of India, which, he said, was in some respects the most remarkable of all; it had provided troops for a larger number of the theatres of war than any of the other overseas contingents. Speaking of the medical service, he said that at the beginning of the war the Royal Army Medical Corps had 3,168 officers and 16,330 other ranks. There were now nearly 14,000 officers and 125,000 other ranks. The health of the army had been better than that of the civil population at home. The nurses had not only been ministering angels in hospitals behind the lines, but had been constantly pushed forward to the very

clearing stations only just behind the front, where they had literally stood between the living and the dead. Seven had been drowned by submarine action and several others had been killed by enemy bombs on hospitals.

In both Houses glowing tributes were paid to the men of the original Expeditionary Force—the old army—and it was appropriate that the vote of thanks was moved and adopted on the third anniversary of the opening of the first battle of Ypres.

Ministry of Health: Hope of Substantial Agreement.—In answer to Sir William Collins, who asked whether some form of inquiry, by Royal Commission or otherwise, into the desirability and practicability of instituting a Ministry of Health would be instituted, Mr. Bonar Law reiterated the hope that substantial agreement would shortly be reached amongst those directly concerned; as the subject has already been very carefully investigated and reported on by the Reconstruction Committee and by a Committee of Ministers, the Government did not consider the appointment of a Royal Commission necessary.

Medical Students in Combatant Service.—In reply to question as to medical students who volunteered for service in the early days of the war, whether, in view of the sacrifices made by them and the services rendered, they would be entitled to recognition as well as combatant officers, Mr. Macpherson said that all these cases were very carefully considered, and regulations were being issued which he hoped would include men of this type. The whole question of the condition of military service as it affected medical students was under consideration by the Ministry of National Service, and representations on the subject would, he was informed, shortly be laid by that Minister before the Army Council.

Territorial General Hospitals.—Colonel Gretton asked, with reference to the regulations for general hospitals of the Territorial Force, which laid down that for each 520 beds there should be, in addition to the medical officers engaged in military duties, four lieutenant-colonels and eight majors selected from distinguished members of the medical profession, for a detailed return showing how many beds there were at the present time in each of the five London General Hospitals and the number of officers of various grades. Mr. Macpherson said that only half of the numbers specified were to be on duty at one time and the employment of the mobilized staff was subject to such modification as the General Officer Commanding of the Command might think necessary. Mr. Macpherson afterwards gave the following particulars as to the London Territorial General Hospitals:

Hospital.	Beds.	Lt. Cols. and Bt. Lt.-Cols.	Majors and Bt. Majors.	Other M.O.s and Civil Practitioners.
1st London ...	1,021	4	4	21
2nd London ...	1,512	2	5	21
3rd London ...	2,400	2	5	36
4th London ...	2,171	2	3	31
5th London ...	662	1	1	16

Medical Treatment and Training of Discharged Soldiers in Wales.—The Secretary to the Ministry of Pensions informed Major David Davies that some 176 institutions, including military, auxiliary, and civil hospitals and convalescent homes, were in use and open to the treatment of discharged disabled men in Wales and Monmouthshire, and the Joint (Disablement) Committees set up by local War Pensions Committees, and the Ministry had been invited to submit proposals for meeting any deficiencies in this respect. Schemes for establishing an after-care colony with training for tuberculosis, and for at least one centre for orthopaedic treatment, were now under consideration. With regard to training, schemes had been sanctioned for cinema operating at Cardiff, cabinet-making and toy-making at Trefnant, and horticulture and market gardening at Wrexham Garden Village. Diamond-cutting and polishing would, it is hoped, shortly be established at Wrexham, and it was proposed to start a number of courses in various subjects at Cardiff.

Nerve Shocked Soldiers and Sailors.—In reply to Mr. King, Sir A. Griffith-Boscawen said that men who were invalidated from either the navy or the army suffering from nerve strain were medically examined by a special expert board. Any representations of local committees or available opinions of medical practitioners were considered. He added, in reply to a further question, that there were thirteen Scottish and Irish doctors serving on the medical boards, and of this number three held posts connected with lunacy. The functions of these boards were solely the assessment of disability for pension purposes, and the recommendation of suitable cases for treatment in

homes of recovery. He could not consider that a special knowledge of mental disorders rendered a medical man unsuitable to exercise the functions to which he had referred.

Home Hospital Men.—In answer to Mr. Tyson Wilson, Mr. Macpherson said that men of the Home Hospital Reserve who are under 41 years of age were now discharged, unless they were willing to accept liability for service overseas. By such discharge they became liable under the Military Service Acts. Mr. Wilson asked whether a large number of these men, if they had remained in civil occupations, would not have been exempt from service in the army.

Disabled Soldiers: Medical Referees.—Mr. Charles Roberts asked the Pensions Minister what arrangements had been made for the appointment of medical referees under Article 12 of the instructions and notes on the treatment and training of disabled men. Mr. Pratt said that a number of applications had been received from all parts of the country, and a Committee of Selection, consisting of representatives of the Central Medical War Committee, the Local Government Board, and the Insurance Commission was considering the qualifications of candidates. The Committee had already made recommendations to cover all the Southern and some of the South Midland counties of England and the whole of Wales; over one hundred medical referees out of a probable total of about four hundred have been appointed.

War Pensions Local Committees.—On the second reading of the War Pensions Local Committees Bill, which has for its object to include the representation of discharged soldiers and sailors on the Committees, Sir A. Griffith-Boscawen said in reply to criticisms that it was intended that discharged soldiers or sailors should be given membership and not mere representatives. The nominations would come before the Pensions Minister, and the representation would not necessarily be limited to one member for each Local Committee. He promised to see that the proposal was made clear in Committee, and the second reading was carried without dissent.

Discharged Soldiers' Minimum Pensions.—Mr. Pratt informed Mr. Byrne that the lowest pension to an invalided soldier—5s. 6d. a week—was one applying only to cases where the disablement was small, interfering little with the man's powers. The cases of grants of 4s. 6d. a week, to which Mr. Byrne had referred, were cases in which the disability, almost always disease and not injury, had been found to be neither due to nor aggravated by service. In such cases the man had a right of appeal to the special tribunal. There was no limit in time to right of appeal, but obviously in case of delayed appeal it was much more difficult to establish the connexion between a man's present disability and service.

Vaccination in Ireland.—In answer to Sir T. Esmonde, Mr. Duke said that resolutions in favour of extending the "conscience clauses" of the English Vaccination Acts to Ireland had been adopted by forty-seven unions in Ireland; had been marked "read" by thirty-two unions; either not adopted or rejected by seven unions; and endorsed "no action taken" by eleven unions. Four unions had deferred consideration of the subject, and the minutes of fifty-four unions contained no reference to the matter. In reply to Mr. Byrne he said that the Local Government Board took every precaution to ensure that the calf lymph supplied was absolutely pure, and their bacteriologists reported that no purer lymph could be produced than that supplied and distributed by the Irish Vaccine Department. The results of the thousands of vaccinations performed each year afforded the best possible experimental proof of its harmlessness.

At a meeting to which all members of the profession in the Exeter Division were summoned, held at the Royal Devon and Exeter Hospital on October 25th, when Mr. G. G. Gidley was in the chair, a memorandum on the medical aspects of the Education Bill, 1917, was read. The meeting resolved unanimously to support the policy of the Association in regard to the opposition to Clauses 18 and 19 of the bill, and to make representations to members of Parliament pointing out the objections entertained by the profession to Clause 18, whereby power to provide treatment is extended to all schools, since it is not for the public good that the treatment of young people should be taken out of the hands of the family doctor.

HENRY VIRTUE SIDDONS, who, as reported in the JOURNAL of September 15th, was committed to the Liverpool Assizes on charges of forging medical certificates and obtaining money by false pretences, has since committed suicide. There were nine charges in all in the calendar. Siddons had been allowed bail in the sum of £1,000.

THE trial ended on October 31st, before Mr. Justice Salter at the Central Criminal Court, of Dr. A. M. R. Sinclair, B. G. Grantway, and J. Trichter, who were charged with offences in connexion with the examination and classification of recruits. The jury found Dr. Sinclair not guilty of the charge of conspiracy to defeat the provisions of the Military Service Acts, and he was acquitted. The other two prisoners were found guilty.

THE WAR.

CARREL-DAKIN TREATMENT OF WOUNDS.

THE Director-General Army Medical Services has received a report on the Carrel-Dakin treatment of wounds by a committee which visited France last summer. The members were Lieut.-Colonels Sir Alfred Pearce Gould, Sir Thomas Myles, C.B., and Albert Carless, and Captains Attwater, Beesley, and Douglas-Crawford. The hospitals visited were M. Carrel's, which at the time of the visit was under the surgical care of M. Guillot; the clinics of MM. Tuffier and Chutro in Paris; the American Ambulance in Paris, and Mrs. Depew's Hospital at Annel. The report is as follows:

REPORT.

The Carrel treatment consists in the application at frequent intervals of a gentle stream of fresh antiseptic fluid to the whole surface of an infected wound, without any interference with the dressings. It aims at obtaining a reduction in the number of pathogenic organisms in a wound until less than 1 per "field" in a smear of the discharge can be found with a microscope. Such a wound is regarded as "clinically sterile." When this standard of sterilization of wounds is attained, it is found that they heal rapidly, without fever, and without the danger of secondary haemorrhage, and that they can be safely closed and "primary healing" be obtained. In "clinically sterile" wounds fractures can be safely plated, and comminuted fractures consolidate without necrosis.

The instillation of the antiseptic fluid is effected by means of small rubber tubes, closed at the end, and perforated with six to eight small holes at half-inch intervals; these are placed on or in the wound in such numbers and in such positions that fluid escaping from them is brought into contact with every part of the surface. These tubes are connected with a reservoir containing the selected antiseptic fluid, which is raised about four feet above the patient. By means of an electric clock, of an automatic siphon, or by a nurse loosening a compressor on the supply tube, a given amount of antiseptic fluid is made to flow out through the tubes and over the surface of the wound. As a rule the fluid is made to pass over the wound every two hours. The interval may be shorter (hourly); rarely is it longer than two hours. The tubes are kept in place by laying sterilized gauze soaked in the antiseptic over them and the whole wound, this deep dressing is covered by dry sterilized gauze, and over all is placed a larger sterilized outer dressing of non-absorbent cotton-wool between two layers of gauze, and this is held in place by a few safety pins. In some clinics a thin inner layer of the outer dressings is made of absorbent gauze and cotton-wool. In M. Guillot's and M. Tuffier's wards we saw the dressings renewed every day. In M. Chutro's clinic the inner dressing is changed daily for three days after an operation, and subsequently every second day, and the outer dressing is renewed only about once a week. We did not notice that M. Chutro's less costly practice was attended with any disadvantage.

Every dressing is made by the surgeon himself under the strictest aseptic precautions. Rubber gloves were worn, two pairs of sterilized forceps were used for each patient, and the tubes were placed, the various layers of gauze laid on, and the outer dressing folded round the limb by these forceps; the gloved hand was never allowed to touch either the wound or the dressing. The surgeon was assisted by a large staff of highly trained and careful nurses, each of whom carried out one step only in the preparation for or the conduct of the dressing. Thus one nurse went just ahead of the surgeon and removed the pins from the dressing about to be renewed, and fastened the pins in each dressing as it was completed; a second nurse attended to the "smears," a third to the "combs," a fourth to the vaseline, a fifth handed the fresh outer dressings, and the sister handed the forceps to the surgeon and then handed him the tubes and the wet and the dry gauze as he required them. This made the technique elaborate and the process rapid. Since our return home we have found it possible to carry out the dressings with two or at most three trained helpers, and without any undue lengthening of the "dressings."

In MM. Tuffier's and Guillot's wards a "smear" is taken

from each wound every second day, the number of organisms per "microscope field" is carefully determined by a skilled observer and is recorded on a bacteria chart, which is kept with the patient's temperature and pulse chart. When the bacteria chart shows a "count" of less than one organism per field on three successive occasions, the wound is considered "clinically sterile," and suitable for closure by operative measures. We saw several cases where such closure had been carried out with success.

The making of these bacteriological observations and counts is essential if the surgeon desires to practise secondary closure of infected wounds.

The charts also afford a valuable index of the success of the antiseptic treatment of the wound. In the cases we saw there was almost invariably a rapid fall of the chart line from "infinity," or from a very high count, to under ten bacteria per field, and most of the wounds soon became nearly or quite "clinically sterile." In M. Chutro's clinic the treatment is carried out on rather simpler lines. In a large number of his cases no bacteria chart is kept, and smears are examined only once in ten days. M. Chutro does not practise closure of formerly infected wounds, and he is therefore not dependent upon a definite assurance that a wound is "clinically sound." He is satisfied if there is no suppuration in a wound, if it steadily heals, and if the patient's general condition is good and the temperature normal.

Provision has to be made against the patient's bed becoming wet from the fluid running out above or below the dressing, or soaking through it. We saw different means used to prevent this.

1. In some cases a large mackintosh sheet covered with a draw-sheet was placed beneath and far beyond the dressing, and the draw-sheet was changed as soon as it became wet. In some cases the outer dressing became so wet that it had to be changed between the surgeon's daily visits; this resulted from allowing an excessive amount of the antiseptic fluid to flow over the wound.

2. In M. Chutro's wards we saw large shallow zinc trays placed beneath the wounded limb or part of the body. The fluid that escaped into these trays was led through a tube into bottles beneath the beds. The patient's back or wounded limb was supported on a large rubber air-cushion. The men appeared to be quite comfortable, and assured us this was so. The wetting of the dressings causes really very little inconvenience when the amount of fluid flowing over the wound is well regulated.

3. We have found large pads of sphagnum moss placed beneath the wound a very simple and at the same time an effective means of avoiding this dampness.

It is recognized by all who use Dakin's fluid or esol that it sometimes causes irritation around the wound. MM. Tuffier and Guillot guard against this in all cases by covering the skin for some distance beyond the wound with a layer of gauze soaked in sterilized vaseline. M. Chutro only applies the vaseline when he sees evidence of irritation of the skin, and then he puts it on thickly by means of a sterilized wooden spatula. This difficulty is real, and must be guarded against. M. Chutro's plan is the simpler of the two, and is certainly effective. We did not see any serious consequences from this irritation of the skin.

In M. Carrel's clinic Dakin's fluid is invariably used as the antiseptic of choice. When a wound has become a superficial and healthy granulating wound, it is usually dressed with chloramine ointment, composed of chloramine 10 parts, stearate of soda 86 parts, and water 4 parts. The percentage of chloramine may be increased to 12 or reduced to 6. Experiments were being carried out to determine which of the many chloramines is the best to use for this purpose.

In M. Tuffier's clinic and in M. Chutro's clinic only Dakin's fluid is used in carrying out this treatment. M. Chutro, with a clinic of 300 military beds, into which he asks for the "worst cases" to be sent, uses no other antiseptic at any stage of the healing of a wound. When it has become quite superficial and is in the condition in which we saw chloramine ointment used by M. Guillot, M. Chutro covers the wound with a layer of wet gauze, upon this he lays a Carrel tube, and over that more wet gauze, and surrounds the part with the usual outer dressing. Many of M. Chutro's cases are very chronic and have been suppurating for months and are frequently complicated with necrosis.

In the Annel Hospital we saw three fluids used with Carrel's tubes—Dakin's fluid, eusol, and ether. We were assured that good results were obtained from each of them. One of the surgeons, M. Lefebvre, expressed a preference for ether. One advantage of ether over other antiseptics is that the outer dressing does not become wet and can often be left untouched for four days. On the other hand, ether is a costly antiseptic, and some of the patients complained of the intense cold its instillation caused. In this hospital the majority of the cases were recent wounds, and many patients arrived within a few hours of being wounded. Such cases are the least severe test of any antiseptic method.

Results.

It is evident that in estimating the value of the Carrel-Dakin treatment care must be taken to appraise quite separately the method of applying the antiseptic and the antiseptic employed. While convinced that the use of Carrel's tubes as we saw them employed is a very valuable means of applying an antiseptic fluid to a wound, we are not satisfied that Dakin's fluid is markedly superior to eusol, and we are prepared to find that other antiseptics can be used with advantage by the Carrel method.

The results of the Carrel-Dakin treatment as seen by us in a large series of unselected cases were strikingly good.

1. The bacteria charts usually showed a rapid fall in the number of bacteria present in the discharge. The more recent the wound the more rapid this fall. In some cases of long-standing infection, particularly in sinuous or pouched or irregular wounds in which there was physical difficulty in bringing the fresh antiseptic into contact with every part of the wound, the fall in the bacteria chart might be long delayed. The presence of a sequestrum or of a foreign body similarly delayed the sterilizing of a wound. M. Tuffier said: "I can sterilize any wound by this treatment." We saw many charts in which the number of bacteria in the smears examined was given as less than one per field (clinical sterility). An operation was often immediately followed for two or three days by a rise in the bacteria count and this was particularly observed where a layer of blood clot had been left in the wound; great care was therefore taken to arrest all oozing from a wound at the time of operation. Anaerobic bacteria were reduced in numbers as quickly as the aerobic, but streptococci were more resistant than staphylococci. We were told of a case in which an operation was carried out in a wound which was the seat of erysipelas, and the result was satisfactory.

2. We saw several cases where infected wounds had become "clinically sterile" under this treatment, and had then been closed by the surgeon, and had healed by primary union. In some of these cases cavities in bone due to comminuted fracture or to chronic osteomyelitis and necrosis had been filled with a graft of subcutaneous fat taken from the patient, the skin edges had then been undermined and sewn together over the graft. Primary union had been obtained and consolidation of the bone had occurred later on. Great stress was laid by all the surgeons we saw upon the necessity of demonstrating in the laboratory the "clinical sterility" of a wound before attempting its closure. Clinical evidence alone is not to be relied upon. Only wounds proved to be practically germ-free ought to be dealt with in this way. We think it desirable to lay special stress upon this point.

3. In one of M. Tuffier's wards we saw a series of cases of chronic empyema, nearly all of them resulting from gunshot wounds many months before admission. By Carrel-Dakin treatment "clinical sterilization" of the cavity had been obtained, and when this fact had been demonstrated M. Tuffier had raised the edges of the wound from the ribs, sutured them, and obtained primary union, although there was still a considerable cavity in the pleura unobliterated. We examined these cases, and found that they were well, with firmly healed scars. Post-pneumonic empyemata are treated in a similar way, and healing is often obtained, we were told, in two or three weeks.

4. We saw a large number of serious wounds from gunshot injuries, treated by the Carrel-Dakin method, in which there was no suppuration. Among these were many cases of compound fracture of the pelvis, femur, tibia and humerus, wounds of the hip, knee, ankle, and shoulder joints, as well as chronic osteomyelitis of various

bones. In M. Chutro's large clinic, for example, we only saw recognizable pus in two cases; in each of these cases the ends of long and deep wounds had been sutured, and tubes had been placed in the open central part. Suppuration had occurred at one end, and was treated by removing the sutures and putting more Carrel tubes into the wound. In cases of badly united fracture of the femur, with shortening and infected sinuses, M. Chutro did not hesitate to divide the bone to obtain proper alignment of the fragments. By heavy extension and Carrel-Dakin treatment of the wound he obtained a clean granulating wound and rapid consolidation of the bone.

5. The wounds granulated well; the granulations were even and florid, and, so far as we could judge, healing progressed rapidly.

6. The patients looked well, and were free from fever as soon as the bacteria count fell. They were free from pain, and made no complaint of the method of treatment. The change of dressing was generally quite painless, and the instillation of the fluid caused at most a sensation of coldness but no pain. We noticed that after operations in which bone had been removed, and tubes and gauze had been placed in contact with raw osseous tissue, they were not removed for some days (four days for the tibia, six for the femur), and in this way the pain caused by early removal was avoided. We saw one case where the change of the deep dressing in a wound of the ankle caused severe pain, necessitating on one occasion the administration of a general anaesthetic. This was said to be due to the exposure of the posterior tibial nerve in the wound.

7. The most striking evidence of the value of the treatment that we saw was a printed notice put up in a prominent place in M. Tuffier's wards, and to which he drew our special attention, as being the expression of his own opinion after a considerable experience of the Carrel-Dakin treatment. The notice is as follows:

Tout blessé qui supprime le droit d'en demander la raison à son chirurgien.

Objections.

Certain objections have been raised to this treatment:

1. It requires the personal attention of the surgeon in charge of the case to each individual patient. This undoubtedly lessens the number of cases that a surgeon can take under his care. M. Chutro estimated that fifty or sixty patients per diem was as many as a surgeon could properly attend to. As a set-off to this, it must be pointed out that patients gain considerably by being always dressed by the surgeon in charge of them.

2. The technique is more elaborate than that of most wound dressings, and, as we saw it carried out, entails a heavy strain upon the nursing staff. The dressing is, however, only changed once in twenty-four or forty-eight hours, and when once dressed, the wound requires very little attention for the rest of the time. If an automatic flushing system is employed, all the nurse has to do is to see that the reservoir is filled at stated intervals, that the bed does not get wet, and that the movement of the patient and the arranging of the bedclothes does not disturb the tube. We have found that it is quite practicable to carry out the system of treatment with two nurses only in attendance upon the surgeon, and that when once the routine is learnt, cases can be dressed very expeditiously; nurses state that the work of the ward is not heavier under this system than under others.

3. It has been alleged that the flushing of the wound every two hours with the antiseptic fluid is disturbing, or even painful, to the patient. We find that at the commencement of the treatment this may be so, but in a very short time the flushing does not wake the patient from sleep, nor does it cause anything more than a passing sensation in the wound when awake.

4. *Expense.*—We are not able to give a definite comparison between the actual cost of a series of patients treated by the Carrel-Dakin system and a similar series of patients treated by other means. Much of the equipment can be used for patient after patient. The rubber tubes can be cleansed and resterilized, and safely used again. The outer dressings oftentimes last a week, and as they are made of unbleached and non-absorbent wool, they cost very much less than dressings of similar size of absorbent wool. Care in the use of these dressings, and the supplementing of them by almost costless sphagnum moss pads reduces the cost very considerably, and we think must

make it less than some forms of dressing, particularly those involving the employment of large quantities of absorbent wool.

5. *Difficulty in Preparing the Fluid.*—Eusol is easily prepared, and in hospitals where large quantities are needed, it can be made fresh every day, and always be of its proper potency. Dakin's fluid is more difficult to prepare, and its preparation has to be carried out with great precision if its proper composition is to be maintained. We give as an appendix to this report the method of preparation recommended by one of our number, Captain Attwater. We do not feel able or called upon to state whether there is such proved superiority of Dakin's fluid over eusol as to justify its invariable use. It is important that these fluids should be protected from the action of light and of heat, but this is easily done.

6. These objections are one and all of small moment when compared with the proved advantages of the Carrel method of treatment. The prevention or arrest of infection of the wound, the greater rapidity of healing, more than repay for any labour or cost that the method involves.

7. If the system is adopted at casualty clearing stations and base hospitals provision must be made for the continuance of the irrigation of wounds during the transit of the patient from place to place. If the method is employed at all it should be employed in its entirety; it is not enough to introduce tubes into a wound and envelop the limb in a non-absorbent dressing, and then to send the patient away on a long journey where there may be no facilities for keeping up the instillation of the antiseptic fluid.

We are of opinion that the Carrel-Dakin method of treatment, if carried out thoroughly, is full of promise, and we believe that it will (1) diminish the dangers incidental to sepsis, including secondary haemorrhage, (2) hasten the patient's convalescence, (3) lessen the liability to stiff joints and cicatricial deformities, (4) enable the patients to leave the hospital with better general health than they otherwise might, and (5) where secondary operations become necessary, these operations are more likely to be free from septic complications than where some other system of primary treatment has been adopted.

Preparation of Solution.

In an appendix to the report Captain Attwater gives minute directions for the preparation of Dakin's solution in the manner suggested by Dr. Daufresne. These details, we gather, will be published in the *Journal of the Royal Army Medical Corps*.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Two torpedo-boat destroyers, H.M.S. *Mary Rose* and H.M.S. *Strongbow*, in charge of a convoy of Scandinavian food ships, were sunk by two heavily-armed German raiders on October 17th between Norway and Shetland. Most of the convoy were also sunk, only three vessels escaping. The great majority of the officers and men, of both destroyers and convoy, were lost, but a few survivors were picked up by a British patrol boat. Among those lost was Surgeon-Probationer Ivan C. C. Barclay, of H.M.S. *Mary Rose*. He was the youngest son of Mr. Charles Barclay, of Rosecraig, Cowdenbeath. Surgeon-Probationer I. M. Thomson of H.M.S. *Strongbow*, is reported saved, but severely wounded.

Killed in Action.

Surgeon Probationer G. Brown, R.N.V.R.

ARMY.

Killed in Action.

Major G. M. Hunt, M.C., Australian A.M.C.

Captain A. M. Fisher, R.A.M.C. (temporary).

CAPTAIN J. ALSTON, R.A.M.C.(S.R.).

Captain James Alston, R.A.M.C., was reported as killed in action, in the casualty list published on October 29th. He was educated at Dublin, took the diplomas of L.R.C.P.I. and L.R.C.S.I. in 1911, and joined the Special Reserve of the R.A.M.C. as a lieutenant on April 6th, 1914, being promoted to captain after a year's service.

CAPTAIN F. C. DAVIES, R.A.M.C.

Captain Frederick Charles Davies, R.A.M.C., was killed in action on October 17th, aged 33. He was the youngest son of William Davies, J.P., of Borth and Battersea, and was educated at Charing Cross Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1908; and at Cambridge, where he graduated M.A. in 1910, M.B. and B.C. in 1911, and as D.P.H. in 1912. He also took the M.R.C.P.Lond. in 1914. After filling the posts of house-surgeon, house-physician, and medical registrar of Charing Cross Hospital; of clinical assistant at the Great Ormond Street Children's Hospital; and of resident medical officer and bacteriologist at the West Ham Corporation Isolation Hospital, he became medical adviser to the Cambridge Insurance Committee, and county tuberculosis officer. He took a temporary commission as lieutenant in the R.A.M.C. on August 10th, 1914, in the first week of the war, and was promoted to captain on completion of a year's service.

CAPTAIN E. J. KERR, A.A.M.C.

Captain Eric John Kerr, A.A.M.C., was killed in action on October 4th, aged 25. He was the second son of Mr. John H. Kerr, Treasury, Melbourne, Australia, and was educated at Wesley College, Melbourne. He received his medical training at the Melbourne University, where he graduated M.B., B.S. in March, 1915. After filling the posts of resident surgeon and physician at the Melbourne Hospital he took a commission in the A.A.M.C. in January, 1916, and sailed from Australia in the following June. He leaves a widow and one child.

LIEUTENANT R. A. RAIL, L.D.S.

Lieutenant Richard Augwin Rail, L.D.S., Grenadier Guards, was killed in action on October 9th, aged 29. He was the youngest son of Mr. John W. Rail, of Wycroft, Kenilworth, Cape Town, and was educated at the South African College, at Charing Cross Hospital, and at the Royal Dental Hospital, taking the diploma of L.D.S. of the Royal College of Surgeons in 1911, after which he went into practice at Capetown. He came home to join the army in February, 1916, got a commission in the Grenadiers, and went to the front in July, 1916. He was well known in South Africa as a cricketer, playing as a member of the Western Province eleven.

Died of Wounds.

CAPTAIN H. GIBSON, R.A.M.C.

Captain Harold Gibson, R.A.M.C., died of wounds on October 17th, aged 33. He was the youngest son of Surgeon Lieut.-Colonel G. J. Gibson, R.A.M.C. (retired), born September 21st, 1884, and was educated at the London Hospital, taking the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1907. He joined the R.A.M.C. as a lieutenant on July 29th, 1907, and became captain on January 29th, 1911. He was acting as a temporary lieutenant-colonel when killed.

Captain F. B. Metcalfe, Australian A.M.C.

Captain J. R. Tillet, Australian A.M.C.

Wounded.

Lieut.-Colonel P. J. Hanafin, D.S.O., R.A.M.C.

Lieut.-Colonel C. W. Thompson, Australian A.M.C.

Major W. H. Rennick, Australian A.M.C.

Captain G. J. Baker, R.A.M.C. (temporary).

Captain F. L. Bignell, Australian A.M.C.

Captain G. A. Birnie, R.A.M.C. (temporary).

Captain G. Crashaw, R.A.M.C. (temporary).

Captain E. P. Dark, M.C., R.A.M.C. (temporary).

Captain T. Duncan, R.A.M.C. (temporary).

Captain T. Faris, New Zealand Medical Corps.

Captain F. W. Fay, Australian A.M.C.

Captain H. Foxton, R.A.M.C.(T.F.).

Captain H. A. Higginson, R.A.M.C. (temporary).

Captain J. Howard, R.A.M.C. (temporary).

Captain F. E. Keane, R.A.M.C. (temporary).

Captain J. A. Liley, M.C., R.A.M.C. (temporary).

Captain E. A. Lumley, R.A.M.C. (temporary).

Captain H. A. Macmillan, R.A.M.C.(T.F.).

Captain F. L. Newton, R.A.M.C.(T.F.).

Captain F. C. Pridham, R.A.M.C. (temporary).

Captain A. E. S. Pringle-Pattison, R.A.M.C. (temporary).

Captain F. W. Stone, R.A.M.C. (temporary).
 Captain W. A. Todd, R.A.M.C. (temporary).
 Captain F. E. S. Willis, R.A.M.C. (temporary).
 Captain H. F. Wilson, R.A.M.C. (temporary).
 Captain P. R. Woodhouse, M.C., R.A.M.C. (temporary).

Prisoner of War.

Captain K. Atkin, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Edwards, Henley Spencer, Private, Middlesex Regiment, eldest son of Dr. A. S. Edwards of Halling, Kent, reported as missing on October 23rd, 1916, now presumed killed on that date, aged 19.

Smith, Eric Drummond, Second Lieutenant Sherwood Foresters, only son of Dr. H. W. Smith, of Pleasley, near Mansfield, killed in action on October 4th, aged 19. He was educated at Margate and Nottingham High School. He joined the Inns of Court O.T.C. in September, 1915, obtained his commission in September, 1916, and died on the anniversary of his going to France.

Thomson, William Robinson Kitchen, Second Lieutenant Royal Garrison Artillery, eldest son of the late Dr. J. Thomson of Gateshead, killed October 15th, aged 31.

NURSES.

Sister E. M. Kemp, Territorial Forces Nursing Service, was reported as killed in the casualty list published on October 27th.

Staff Nurse Ella Kate Cooke, Q.A.I.M.N.S. Reserve, was accidentally killed at Alexandria on September 8th. She was the youngest daughter of the late Henry Cooke of Auckland, New Zealand.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SUPPLEMENT to the *London Gazette* issued on October 27th contains a list of rewards for gallantry and distinguished service in the field, which includes the following officers of the R.A.M.C.:

Awarded the Distinguished Service Order.

Temporary Captain John Caruthers Sale, M.C.

Awarded Bar to the Military Cross.

Temporary Captain Hugh Ross MacIntyre, M.C. (M.C. gazetted August 16th, 1917).

Awarded the Military Cross.

Temporary Captains Leslie Haden Guest, William Illewellyn Apin Harrison, William George Johnston, Robert Kennon, M.D., John Kirtton, M.B., Wilfred John Pearson, M.B.

Temporary Lieutenant Henry Marston Layard Crawford, M.D.

Temporary Quartermaster and Honorary Lieutenant Charles Elliot.

FOREIGN HONOURS.

Mr. H. S. Souttar, M.Ch., F.R.C.S., has received His Majesty's permission to wear the insignia of Officer of the Order of the Crown conferred upon him by the King of the Belgians in recognition of valuable services rendered.

NOTES.

THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY.

The war establishment of a division of the United States army consists of 909 commissioned officers and 26,868 men; the medical department has 117 medical officers and 1,332 enlisted men. In the total of medical officers is included apparently 8 veterinary officers, so that the number of medical officers is 109, which is at the rate of one medical officer to 247. The medical personnel and equipment is in two parts: (1) The sanitary train, consisting of field ambulance companies, hospital companies, and camp infirmaries; (2) the medical department personnel attached to mobile line units such as regiments of infantry, cavalry, artillery, engineers, and signal corps battalions. Lieut.-Colonel W. W. Reno, from whose articles in recent issues of the *New York Medical Journal* we take this information, states that the sanitary train has 49 commissioned medical officers and 878 enlisted men, nearly all of them in four field hospital companies and four ambulance companies. The camp infirmary is simply a wagon load of supplies available for the emergency treatment of the sick in one-night camps and in peaceful situations, but it also furnishes surgical dressings and other medical equipment to troops on the line in time of war. The units of the sanitary train

are commanded by a medical officer, and the whole sanitary train by a division surgeon. The full strength of a regiment of infantry appears to be 103 officers and 3,652 men. The number of medical officers is four, one being a major; the number of non-commissioned officers four, and of privates 29. The medical personnel with regiments is under the immediate command of the colonel of the regiment, but the senior surgeon is in command of his medical personnel. At divisional head quarters are two lieutenant-colonels and a major. The duties with which the medical department are charged are: (1) Investigating the sanitary condition of the army and making recommendations in reference thereto; (2) advising with reference to the location of permanent camps and posts; (3) adopting systems of water supply and purification and the disposal of wastes; (4) caring for the sick and wounded; (5) making physical examinations of officers and enlisted men; (6) managing and controlling military hospitals; (7) recruiting, instructing, and controlling the enlisted force of the medical department and the nurse corps, and furnishing all medical and hospital supplies. The surgeon of every post or command supervises its hygiene and reports in writing to the commanding officer, who, in forwarding the report to the Adjutant-General, must state his reason for not accepting any recommendation made by the surgeon. In practice, however, it is found that a commanding officer seldom fails to remedy any defects pointed out to him. The Medical Department comprises the following branches: 1, the Medical Corps; 2, the Medical Officers' Reserve Corps; 3, the Dental Corps; 4, the Veterinary Corps; 5, the Army Nurse Corps (female); and 6, an enlisted force, supplying non-commissioned officers, male nurses, pharmacists, clerks, cooks, ward masters, surgical and bacteriological assistants, hospital attendants generally, drivers, chauffeurs, blacksmiths, farriers, mechanics, and other men needed to carry on the many activities of the Medical Department. From another source we learn that each American army in France, consisting of three army corps, will have a water regiment of six companies, and an engineer regiment of six companies for handling attacks by gas and liquids.

AMERICAN ORTHOPAEDIC UNITS.

Major Joel E. Goldthwait, M.R.C., U.S.A., has returned to Europe bringing with him from the United States forty-two medical officers who will be distributed through the British orthopaedic centres and later drawn for American orthopaedic hospitals in France. They will receive training in British hospitals while serving under the American officers who were members of the first orthopaedic unit brought over by Major Goldthwait in June last. When after this training they are drawn to the American service another group will be sent from the United States to take their place, and so on in successive groups. In this way a large number of positions will be filled for the work under the British Director of Military Orthopaedics by well-trained surgical assistants. The training of these younger men will fall upon the American orthopaedic surgeons, while at the same time they will help to supply Sir Robert Jones with a large staff to meet the expansion of the orthopaedic service. In addition Major Goldthwait is accompanied by three officers commissioned in the American Sanitary Corps who will be employed in the establishment and development of the American curative workshops.

CLASSIFICATION OF SOLDIERS.

An Army Council instruction has been issued fusing the medical categories B and C into a new category B. If it is proposed to send abroad men in categories lower than A, they will undergo a special medical examination to determine whether they are fit for service in North-west Europe only or in any overseas theatre of war. From November 1st all warrant officers, non-commissioned officers, and men serving at home will be classified in the new categories, and all soldiers classified C 1, C 2, or C 3 will automatically belong to the corresponding subdivision of the new category B.

The New Category A includes men fit for general service—that is to say, able to march, see to shoot, hear well, and to stand active service conditions. There will be four subdivisions: (1) Men actually fit for general service in any theatre of war; (2) recruits who should be fit for A (1) as soon as trained; (3) men who have previously served with an expeditionary force and who should be fit for A (1) as soon as hardened; (4) men under

19 who should be fit for A (1) or A (2) when they attain the age of 19.

The New Category B includes men free from serious organic disease and not fit for general service, but fit for service at home, or abroad if passed fit for service overseas. There are three subclasses: (1) Men able to march at least five miles, see to shoot with glasses, and hear well, and deemed to be fit for service in field units (at home only) and in garrison units or on duties of an analogous nature; (2) men able to walk to and from work a distance not exceeding five miles and to see and hear sufficiently for ordinary purposes, who will be employed in labour units or on garrison or regimental outdoor employment; (3) men only suitable for sedentary work or such duties as storemen, batmen, cooks, orderlies, sanitary duties, etc., or, if skilled tradesmen, at their trades.

There is a temporary category D for men temporarily unfit for service in categories A or B, but likely to become fit within six months, and meanwhile either in command dépôts, regimental dépôts, or in any units under or awaiting medical or dental treatment. At the end of such treatment a man will rejoin his original category until transferred either upwards or downwards by the medical officer or travelling medical board.

England and Wales.

FAILURE OF SANATORIUM BENEFIT IN LONDON.

It was reported to the London Insurance Committee on October 25th that over 500 insured persons suffering from tuberculosis were awaiting institutional treatment, and that this was the highest waiting list yet recorded. The number of beds available, all at present fully occupied, was 459, and the number of applications annually for institutional treatment was approximately 2,500. The Committee considered a report from its medical adviser, Dr. Noel Bardswell, upon the policy to be pursued with regard to institutional treatment, in which it was suggested that to maintain the waiting list at a workable figure, as the Committee was hampered by lack of funds, the policy should be to give to every person for whom institutional treatment had been recommended, and who was, in the medical adviser's opinion, likely to benefit from it to the point of restoration in some degree of the capacity for work, a minimum of four weeks' residence, the period to be extended if deemed desirable and possible. This course ensured that every patient who was capable of improvement had the opportunity of learning the principle of the treatment he should follow. As a means of safeguarding from infection those associated with the patients at home or at work, a course of education in a sanatorium, even if limited to only a few weeks, was of inestimable value; but, of course, the shorter the duration of institutional treatment, the more necessary it was to have an efficient system of after-care. A long waiting list defeated the object of sanatorium benefit in that early and curable cases not infrequently developed into cases of advanced disease while waiting for a bed. To admit patients within four weeks of acceptance, the waiting list should be about 150. One or two members expressed grave dissatisfaction with the proposed procedure, and thought it would be better to select from all the cases recommended those most likely to make a permanent recovery and to give them preference in the shape of several months' residence, the remainder to receive domiciliary or dispensary treatment; moreover, it was pointed out that the list was already the result of selection. Dr. Lauriston Shaw, vice-chairman of the Sanatorium Benefit Subcommittee, said that the period of four weeks was accepted by it rather as affording an opportunity of getting a clearer idea as to which were suitable cases and which were not than as offering treatment of much value. The Subcommittee endorsed Dr. Bardswell's suggestion with great reluctance as a means to an end, and the main Committee accepted the recommendation and decided to make a preliminary month's education and treatment the basis of its institutional recommendation.

LONDON COUNTY ASYLUMS.

The Asylums and Mental Deficiency Committee of the London County Council has approved the plan suggested by the Board of Control with regard to the provision to be made at asylums for disabled sailors and soldiers, patients therein who have been discharged on account of mental disorder due to or aggravated by war service. They will not be classed as paupers but as service patients, being placed on the register as such when

notice is received from the Ministry of Pensions. The cost of their maintenance is to be defrayed by the Government, in addition to which a special grant up to 2s. 6d. a week is to be made for extra comforts for patients able to appreciate them. The patients would be on the same legal footing as private patients. It was reported at the same meeting that a patient in the Colney Hatch Asylum had developed symptoms of leprosy and that the diagnosis had been confirmed by microscopical examination.

THE LIVERPOOL MEDICAL INSTITUTION.

The seventy-ninth session of the Liverpool Medical Institution was opened on October 25th by an inaugural address by the President, Dr. Charles J. Macalister. There was a numerous attendance of members, many of whom were in khaki and not a few on furlough from the front. An innovation was the invitation to ladies to be present. The subject of Dr. Macalister's address was "Professional Anecdotes," culled from his own experience. Judging from the applause of his audience, Dr. Macalister is to be congratulated on his departure from the beaten track that inaugural addresses are wont to follow. At a time like the present it is good for the medical profession, amid so much that is grave and serious, to enjoy the lighter side of medical experience. Certainly Dr. Macalister succeeded in entertaining his audience with many amusing and at times comical experiences that had fallen to his lot. Refreshments were provided and so afforded the opportunity of a conversazione. The evening terminated in a concert of vocal and instrumental music. The Misses Sheila and Elsbeth Macalister, daughters of the President, Mrs. Frank Jeans, Captains McFarlane and Llewellyn Morgan, Dr. Petlick and Mr. Brian Imlach were the executants. The topical allusions in Dr. Petlick's humorous songs were received with much applause.

ROYAL MEDICAL BENEVOLENT FUND.

Further contributions to the offertory at the annual medical service held in Liverpool on Sunday, October 14th, brought the amount up to £59 11s. 10d., and, after deducting the necessary expenses, the Royal Medical Benevolent Fund has benefited to the extent of £51. The committee, and especially the honorary treasurer, Mr. R. J. Hamilton, is to be congratulated on the success of their efforts, especially when so many charitable claims are being brought forward at this time.

Scotland.

OPENING OF THE WINTER SESSION, GLASGOW.

The period for matriculation at the University of Glasgow closed on October 25th, and though a few additional students may be enrolled the numbers are not likely to be materially altered. This year the number of men is about 650; on the corresponding day last year the number was 720. At present the only male students of medicine at the University of Glasgow are a comparatively small number approaching the completion of their course, a few who, being unfit for service or discharged from the army, are continuing their studies, and the new students whose course under present regulations will be interrupted by a call to military service when they attain the age of 18. The decision of the Ministry of National Service as to the demobilization of medical students now serving with commissions or in the ranks, is awaited with interest. The decision, it will be remembered, will be taken on the advice of a special subcommittee of the Advisory Committee. The number of graduates, students and alumni, now engaged directly on naval or military service is 3,172, and of these, 2,493 hold, or have held, commissions, 313 have been killed or have died of wounds, 489 have been wounded, and 33 are returned as missing or prisoners of war. The number mentioned in dispatches is 200. Two members of the university have received the V.C., 24 the D.S.O., 120 the Military Cross, and 11 decorations from the French Government. Of honours received by senior graduates, two have been made C.B., one K.C.M.G., and two C.M.G. The university staff is now reduced by war service to the lowest number compatible with supplying the necessary

avenues to degrees. The activity of the Officers' Training Corps continues; 1,400 of its cadets have gained commissions, of whom nearly a thousand are graduates or students. The number of women students matriculating at Queen Margaret's College this year is 760, as compared with 717 a year ago, and 619 in 1914. A considerable proportion of the women students are taking the medical course. Many women graduates and students are doing war work in Government offices, the Ministry of Munitions having claimed a number as medical officers, analytical chemists, superintendents, clerks, or welfare workers.

SCOTTISH NON-PANEL DOCTORS AND A MINISTRY OF HEALTH.

The annual meeting of the Medical Guild—an organization of non-panel practitioners for the purpose of opposing the National Insurance Act—was held on October 27th in the library of the Royal College of Physicians, Edinburgh, under the presidency of Dr. John Playfair. The principal topic under discussion was the proposal to create a Ministry of Health, and the Prime Minister's postponement of legislative action was approved. The President maintained that to rush such a measure through Parliament without due consideration and criticism, especially when so many medical men were absent on military service, would be most undesirable. This view was strongly supported by Dr. Frederick Porter (Edinburgh), Honorary Secretary of the Guild; Professor William Russell, President of the Royal College of Physicians, Edinburgh; and Dr. Duncan, President of the Faculty of Physicians and Surgeons, Glasgow. Sir David McVail, who spoke by invitation, said that there could be no doubt that an effort was being made to reduce the medical profession to a bureaucratic servitude, in which case its work and position would be so revolutionized that the profession as they knew it would no longer exist. Professor Russell, in the course of his speech, insisted that no such measure as a Ministry of Health ought to be proceeded with until the medical profession had been definitely consulted in the matter. He spoke of various schemes, such as that for a State medical service, which were being discussed in connexion with a Ministry of Health. A State medical service would mean the State servitude of the profession, while for the public it would mean no free choice in the selection of a medical man. As for the conversion of voluntary hospitals into State institutions he would oppose that to his last breath. The meeting unanimously decided that steps should be taken to maintain the freedom and independence of the medical profession by organization for mutual support and united action.

LECTURES AT GRETN.

A course of lectures arranged by the Chadwick trustees is being given at the Munition Factory Institute, Gretna. The first delivered by Professor Noel Paton, F.R.S., on October 26th, dealt with food in war time. He said that a shortage was certain because (1) the world's production was decreased by diversion of labour from the tilling of land to military purposes; (2) the supplies were limited by the isolation of such food-producing countries as Russia; (3) the importation of food was decreased by the diversion of shipping to military purposes, and its destruction by submarines, so that, for example, abundant supplies of wheat in Australia could not be brought to us; and (4) the demand for food had increased owing to the strenuous work that was being done. The increase of the cost of food was due to various causes and too much had been attributed to profiteering. As industrial products did not now go to pay for imported food, but were dissipated in munitions of war the credit of the country had suffered and the price of food from abroad had increased. Again, increased earnings had increased the demand for food and so tended to raise the price. This again led to further demands for increased wages, and thus, step by step, the price had been forced up. Generally speaking, down to May, 1916, the increase in the wages of all the organized trades had kept pace with the increase in the price of food. But those families in which the wages of the breadwinner did not rise above 30s. a week had suffered severely. The Government was striving to increase food production at home, but this would tell only in the somewhat distant future, and all that could now be done was to secure a fair distribution of food between all classes. Rationing, with all the expense and irritation of an army of officials, was

inevitable unless the individuals who made up the nation voluntarily conserved the food supply, especially by the avoidance of waste and of overeating made possible to large classes by the rise in wages. The next lecture at Gretna will be given on November 23rd, at 7.30 p.m., by Professor H. J. Spooner, of the London Polytechnic, on "Fatigue and the Worker: Causes, Effects, and Reliefs." The third lecture will be given by Sir John Stirling-Maxwell, Bt., on December 14th, at 7.30 p.m., on "Forestry as an After-war Employment."

Ireland.

OPENING OF THE WINTER SESSION, BELFAST.

The opening lecture was delivered at the Royal Victoria Hospital, Belfast, by Dr. Calwell, Physician to the Hospital, in the Edward VII Memorial Hall, on October 18th. He welcomed the students, old and new, to the practical half of their training when they first had to deal with men and women, and advised them to study the individual as well as the disease. The war marked one of the great decisive epochs in human history. Was the Prussian militarism to obtain mastery in Europe, or was a slowly widening democracy to rule for the benefit of the many? The duty of all was to give such help as they could to bring the conflict to a successful issue, to afford aid to those that had fallen, and to prepare by education for the large changes that would take place in the future. Although no compulsion was upon them, five of the full staff of the hospital were at the front; all the auxiliary staff who could go were or had been there. Many of their colleagues throughout the town and province had given up their private work. They were all proud, not only of those who had received honours, but of all who had voluntarily gone. Dr. McKisack proposed, and Lieut.-Colonel Mitchell seconded, a vote of thanks to the lecturer. Sir John Byers, chairman of the medical staff, in conveying it, referred to the work of an old student, Major Robert McCarrison, M.D., D.Sc., F.R.C.P., I.M.S., whose studies on the thyroid gland had advanced medical science; and on behalf of his old friends and teachers he sent him their warmest congratulations.

MATERNITY AND CHILD WELFARE.

In a note published last week on the war-time economy exhibition in the Belfast Art Gallery and Museum it was stated that in connexion with the exhibits illustrating various phases of welfare schemes a course of lectures would be given. The first of these, on the problem of maternal and child welfare, was delivered by Sir John Byers on October 23rd. He said that not only was there a falling birth-rate, but that far too many mothers and children were dying from preventable causes. In this war the very best blood of the empire was being lost, the flower of their manhood, the potential fathers of the next generation. In England and Wales the Midwives Act was passed in 1903, and the deaths from puerperal fever had been falling ever since. In Ireland matters were not improving, and a similar Act was required. Maternity and pre-natal clinics were required. Infant mortality in Russia was 254 per 1,000 births; in New Zealand, by a splendidly organized State and voluntary system, it had fallen to 50, and in the city of Dunedin to 40. In 1916 it was 91 in England, 97 in Scotland, and 83 in Ireland, but was 153 in Dublin and 113 in Belfast. In Belfast 1,067 children had died during the first year of life, or about one-sixth of all the other deaths; one-third dying from stated causes died in the first month. As many deaths occurred before birth as in the first year after birth. This proved the vast importance of looking after expectant mothers. Any scheme which did not embrace pre-natal care only faced part of the problem. Great progress had been made as regards environment after birth, but this was insufficient. This new work was being done in Great Britain, America, and New Zealand. Pre-natal departments at maternity hospitals were required, where expert advice and treatment were available.

DOCTORS OF MILITARY AGE AND POOR LAW MEDICAL APPOINTMENTS.

The Chief Secretary for Ireland has written to the Cashel Board of Guardians (co. Tipperary) stating that the Local

Government Board has informed him that it wrote to the guardians on May 2nd last calling their attention to the Board's circular of September 22nd, 1916, which dealt with the appointment of men of military age to vacancies in the Poor Law medical service. The Board pointed out that to allow such appointments would do a great injustice to young medical men whose sense of duty had made them offer their services in the R.A.M.C. and who, but for their absence on military service, would be competitors for these vacancies. The Chief Secretary concurs with the Local Government Board in the view it has expressed, and is not prepared to interfere with its discretion in the matter. In reply the guardians have pointed out to the Chief Secretary that they did not ask him to take any action that would deprive members of the R.A.M.C. of the opportunity of competing for the position of medical officer for the Fethard dispensary district when the war is ended. The vacancy, when it occurred, was duly advertised in the local and Dublin newspapers, and Dr. Stokes was the only medical man who offered his services. The district was previously known to him, as, with the sanction of the Local Government Board, he had done duty for the late Dr. O'Connell during the war, and having then acquired an acquaintance with the people and they with him, they naturally desired that his services should be retained. The guardians agree with the Chief Secretary that appointments should be left open for all young men who are at the front to become competitors for vacancies in all positions at the termination of the war, and therefore that such positions should not be permanently filled; they have asked only that Dr. Stokes may be appointed temporarily during the period of the war. The Fethard district is a large one, with an area of more than 29,000 statute acres and a population of close on 4,000 people, with Fethard town in the centre containing nearly 1,600 people, mostly of the labouring class, and Dr. Stokes's application being the only one before the guardians, it could not be expected that they would have so little interest or sympathy with the people of the district that they would leave it without a doctor to look after the interests of the people in the matter of health. There was no course open to the guardians except to appoint the only applicant for the position. At any time there was but the one doctor resident amongst the people of the district—the dispensary medical officer—and Dr. Stokes has his residence and practice, and is the only medical man at present in the district. The guardians have pointed out that he did not propose to give up his private practice and join the army at any time, and therefore his appointment to the charge of the district temporarily during the war in no way militated against the interests of the army, and would not prevent any others from competing for the position as soon as the permanent appointment is advertised after the war. There is no doctor living nearer to Fethard than eight miles, and this doctor has a town as well as a large district to look after, and could not take charge of both districts. The guardians conclude by expressing the hope that with this explanation of the circumstances Mr. Duke will consider the matter again with the Local Government Board.

ORGANIZATION OF NURSES IN IRELAND.

The Irish Nursing Board proposes to organize the nurses in Ireland so as to enable them to manage their own affairs and compile their own register. It hopes to standardize and improve the training of nurses, and to grant a certificate. Its affairs will be managed by an elected council.

Correspondence.

THE CURE OF INGUINAL HERNIA.

SIR,—I am interested in Lieut.-Colonel Hull's account of his method, though, beyond the fact that he makes an incision through the fibres of the external oblique, instead of splitting it from the apex of the external ring, the method is, in essentials, only the same as, I am sure, many others besides myself in children's hospitals have practised for many years.

The principle to be aimed at is that which Hamilton Russell laid down, that for the cure of a congenital

inguinal hernia the only thing which is necessary is the removal of the sac, and *the whole sac*.

The principle which Lieut.-Colonel Hull lays down is "to remove the sac at the highest possible level with the minimum disturbance." Now I have no doubt that with his experience he does remove *the whole sac*, but I am only writing this note to point out that for inexperienced operators this is not a sufficient guide. It is necessary to pull down the sac until a layer of extraperitoneal fat is seen surrounding it. This fat marks the junction of the sac with the parietal peritoneum, and the surgeon must transfix and ligature at this point or above it. The commonest mistake and the only cause of recurrence in children is to ligature below this point.—I am, etc.

London, W., Oct. 29th.

JOSEPH CUNNING.

SIR,—I have read Lieut.-Colonel Hull's able article on the cure of inguinal hernia with the greatest interest. He must certainly be allowed to speak with authority as a surgeon who is operating on 500 cases per annum. There are certain points in his paper, however, which have not been made quite clear, at least to me.

He mentions the presence of an abnormally long process of omentum as a feature of almost constant appearance, and considers it an important factor in recurrence. I cannot recall the experience of any other author which supports this, although the importance of lipomata has been pointed out by several. After a fair experience of the operation I could not say that I have found omentum by any means frequently in the sacs of men below middle age.

Colonel Hull makes a one-inch incision in the skin, and an opening of half an inch in the external oblique aponeurosis. The centres of these incisions are, I take it, just lateral to the line of the femoral vessels. He finds the sac as soon as he has opened the spermatic fascia. That is to say, he deals with typical conditions. I have not always been able to identify the sac so easily, particularly when confronted with the so-called infantile type, and not infrequently I have found the sac behind the elements of the cord.

It has not been my experience that a ligatured sac stump lies behind the *rectus* muscle.

The author states that, if necessary, the conjoined tendon can be stitched down to Poupart's ligament without enlarging the incision. He will remember that at the part of the canal where he is working the internal oblique and transversalis are muscular, and that the tendon lies a fair distance, relatively speaking, nearer the middle line. It must surely require most unusual dexterity to insert a needle through his tiny opening in the external oblique aponeurosis, thrust it adequately through the deep aspect of Poupart's ligament, and then get a firm grip on the rather distant conjoined tendon, to say nothing of the jeopardy in which the adjacent femoral vessels are placed by the manoeuvre.

He makes no reference to the value of his operation in direct hernia, a condition which must crop up every now and again in his large number of cases.

I am bound to admit that the points raised here do not affect the majority of cases, but they concern difficulties which cannot always be anticipated, and I regret that Colonel Hull did not enlarge upon them in his excellent article.—I am, etc.,

Glasgow, Oct. 29th.

CHARLES BENNETT, M.B.

GOLD-CROWNED TEETH AS A SOURCE OF DANGER.

SIR,—Under this heading a short article appears in your issue of October 27th. I heartily agree with the tenor of Mr. Green's communication, excepting that its inference is that teeth with pulp cavities containing the septic residue of necrotic pulps or septic material from whatsoever source owe their virulence to their being gold-crowned. This, of course, is not so. The serious affection of the patient's health arises because of the septic condition of the pulp canals in these "dead" teeth, which canals have either not been treated at all or have been for some reason unsuccessfully treated prior to the actual crowning. The gold crown is a superstructure merely, which does not affect the question. If the tooth had been filled with amalgam or cement or gutta-percha, the result would

have been the same. Of course, many crowns are defectively made and are objectionable as causing retention of food and micro-organisms about the gums; but this ill effect is trifling compared with that caused by a septic condition of the pulp canals. Micro-organisms in this situation (the pulp canals) penetrate through the unfilled apical foramina into the tissues of the alveolus and later on possibly of the jawbone more widely and into the attendant lymphatic glands, and possibly become diffused throughout the system in a general septicaemia. Therefore it is incumbent on the dentist either to extract "dead" teeth or to take the greatest care in treating their pulp cavities in the most careful and scientific fashion before either "filling" or "crowning" them.—I am, etc.,

London, W., Oct. 30th.

H. BALDWIN.

THE DISCOVERER OF THE CAUSE OF SLEEPING SICKNESS.

SIR,—I am loth to enter into the correspondence on this subject, but for the sake of historical accuracy Dr. Nabarro's statements cannot be allowed to pass unchallenged.

To one like myself who is acquainted with the whole details it is certainly amusing to note that Dr. Castellani should have found a champion in Dr. Nabarro. The latter claims to be in "a unique position" to know the entire history of the proceedings. It so happens that I myself was, I will not say in a unique, but in a much more favourable position even than Dr. Nabarro, who, it must be remembered, knows nothing whatever in regard to the delicate negotiations and consultations which took place during the first few days after the arrival of Sir David Bruce and himself. I would ask Dr. Nabarro whether he does or does not believe the story which has already been published dealing with a conversation between Dr. Castellani and myself which took place a few minutes before the Commission landed from the steamer at Entebbe. If I am, to put it euphemistically, a dreamer of dreams, Dr. Nabarro's views may or may not be correct, but, if my story is a record of facts, it for ever destroys any claim which Dr. Castellani can bring forward to be the discoverer of the relationship which exists between trypanosomiasis and sleeping sickness.

When Dr. Castellani came across the trypanosome he quite overlooked its possible importance. He was at the time obsessed by the idea that he had traced the cause of sleeping sickness to a coccus which he had isolated, and he had already been publicly announced, rather prematurely as it turned out, as the discoverer of the cause of the disease. It is noteworthy also that up to the time of Sir David Bruce's arrival he had made no attempt to follow up the clue presented by the presence of trypanosomes in a few of the cases examined by him. Only a few days before the Commission arrived I myself saw Dr. Castellani much distressed at what he described as the unfair attitude of the Royal Society in refusing to publish his original paper on the coccus.

He bitterly resented the coming of another Commission to confirm his work. His first intention had been to leave Entebbe by the returning steamer the next day, and he told me that he would refuse to give the Commission any information or assistance. After meeting Sir David Bruce he eventually parted with his information as to the trypanosome, which a few days previously had been observed by Dr. Baker in a case of sleeping sickness. When Dr. Castellani saw what importance Bruce attached to the observation his faith in his own coccus began to wane, and he expressed the wish to remain with the Commission, but his refusal to work with his present champion, Dr. Nabarro, placed Bruce in a most awkward position. Personally, knowing all the details, I am of opinion that Sir David Bruce was much too long suffering, for, Dr. Nabarro being a member of the Royal Society's Commission, Dr. Castellani's attitude was, to say the least of it, most unreasonable.

Eventually a *modus vivendi* was arranged, and it was agreed that Dr. Castellani should remain for a short while, and that he should take home the first interim report on the work of the Commission. As regards that report Dr. Nabarro's imputations are unworthy. It was written, as I know, by Bruce, and embodied the results of the investigations, not of Castellani alone, but of the whole Commission, assisted, I may say, by the medical staff at Entebbe. Sir David Bruce most generously acknowledged

the debt he owed to Dr. Castellani for having drawn his attention to the presence of trypanosomes in some cases of sleeping sickness, and that sums up the whole of Castellani's contribution to the elucidation of the subject.—I am, etc.,

R. U. MOFFAT, C.M.G., M.D.,
Late P.M.O. Uganda.

London, W., Oct. 11th.

ONE POOL ONE AGREEMENT.

SIR,—Under the new regulations non-panel practitioners are to be allowed to participate in the present common pool without signing the common agreement which is attached to it. The pool up to now has been dealt with solely on a capitation basis, but these non-panel men are to have a special agreement to enable them to participate in this pool solely upon an attendance basis.

The question arises here whether the pool can be used for this double purpose—that is, allowing for an attendance basis for one class of men and a *per capita plus* attendance basis for another class of men. This question will more forcibly arise when the final lading out of this pool takes place. After all charges for attendance, etc., have been paid out of it the panel doctors will as usual share between them the capitation shortage or depletion from which the non-panel doctors are absolutely exempt. If there is to be a special agreement, surely there should be a special pool created and kept entirely separate from the other pool, in which both panel and non-panel men can participate upon an attendance system of payment by both of them signing the special agreement which attaches to such special pool.

What objection there can be to a special pool created apart from the common pool I cannot see, unless the object is to play off one system of payment against another system and thus to confuse the whole issue to the detriment of panel practitioners. To one common pool there must only be one common agreement.—I am, etc.,

Stalybridge, Oct. 28th.

ADAM FOX.

The Services.

AUXILIARY ROYAL ARMY MEDICAL CORPS FUNDS.

Officers' Benevolent Branch.

THE following donations of £3 3s. and upwards were received for the Officers' Benevolent Branch from July 1st to September 30th, 1917:

	£	s.	d.
Meat and Allied Trades Committee, per Red Cross and Order of St. John	...	5	0 0
R.A.M.C. Charities, Blackpool	...	20	0 0
Lieut.-Colonel C. Mansell Moullin	...	5	5 0
90 Field Ambulance (Officers' donation)	...	52	10 0
Captain M. Dixon, per Major Newton Pitt (1,000 francs)	...	36	4 8
R.A.M.C. Dépôt, Blackpool (Officers' donation)	...	5	15 6
Captain M. Dixon (100 francs)	...	3	12 1
M. H. G. F.	...	100	0 0
Colonel D. Hepburn, C.M.G.	...	20	0 0
		£249	7 3

Relief Branch for Widows and Orphans of N.C.O.'s and Men.

The following grants were received for the Relief Branch during the quarter ending September 30th, 1917:

	£	s.	d.
Half of cheque from No. 2 Division, France	120	10	0
Lieutenant J. Byrne	...	1	1 0
Captain J. C. Neil	...	1	0 0
Regimental Institutes, R.A.M.C. Dépôt, Blackpool	500	0	0
No. 11 General Hospital	...	20	0 0
R.A.M.C. Companies, Egypt	...	3	0 0
No. 11 Field Ambulance, half of cheque to R.A.M.C. Fund	...	3	13 6
R.A.M.C. Charities, Blackpool	...	55	18 3
From R.A.M.C. Fund, half of cheque for 5,456 francs	...	100	0 0
99 Field Ambulance	...	52	10 0
Codford Training Centre, Blackpool	...	5	5 8
43rd General Hospital, Salonica	...	50	0 0
J Corps Rest Station, France, 1916-17, per Colonel White	...	11	18 0
Queen Mary's Military Hospital, Whalley	...	50	0 0
No. 4 Stationary Hospital, part of cheque to R.A.M.C. Fund	...	11	0 0
No. 41 General Hospital, Salonica	...	27	0 0
No. 25 Motor Ambulance Convoy, per Captain Stringer, 1,500 francs	...	54	10 10
		£1,067	7 3

The Secretary of the Funds is Lieut.-Colonel E. M. Wilson, R.A.M.C., 124, Victoria Street, S.W.

EXCHANGE.

DOCTOR under Scottish Command. War Office, wishes to exchange post with doctor under London Command.—Address, No. 3750, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.2.

Obituary.

JOHN GORDON SHARP, M.D. EDIN.,

LEEDS.

DR. GORDON SHARP of Leeds died there in the early morning of October 16th with tragic suddenness; he had been at work on the previous day.

John Gordon Sharp, who was 55 years of age, was a native of Keith, Banffshire, Scotland. He graduated M.B. Edin. in 1891 and M.D. in 1896, and had studied also in Manchester, Paris, and Berlin. He won the Milner-Fothergill Gold Medal in Therapeutics (University of Edinburgh), and was awarded the Hunterian Society's Medal, 1910, for an essay on ergot. He made many important contributions to medical journals on pharmacological and other subjects, medical and non-medical. He was a member and foreign corresponding secretary to the Therapeutical and Pharmacological Section of the Royal Society of Medicine.

Dr. Sharp went to Leeds in 1895 and spent the whole of his medical career in that city. He was an active member and at one time chairman of the Leeds Division of the British Medical Association, and also a research student of the British Medical Association and of Owens College. He had been honorary physician to the Leeds South Dispensary and honorary medical officer to the Beckett Home, Meanwood. Although over military age and not in robust health, Dr. Sharp did twelve months' military service with the R.A.M.C. in South Shields and Clipstone camp, and for the past year and up to the day before his death had done military work at Chapeltown Barracks, Leeds.

Dr. Sharp had decided views on the place of alcohol in therapeutics, and by his writings and lectures did much good work for the cause of temperance; his was the strenuous endeavour of a modest, honest, and conscientious man. For many years he was secretary of the Leeds Branch of the British Medical Temperance Association.

Dr. Sharp leaves a widow and two daughters; a brother, Colonel A. D. Sharp, C.M.G., is now in France on military service.

He was buried at Lawnswood Cemetery on October 19th: the day was a perfect October day. Patients, friends, and men representative of the various activities of the city showed their respect and their appreciation of his civic worth by their presence at the last rites.

Universities and Colleges.

PARLIAMENTARY REPRESENTATION OF UNIVERSITIES.

THE scheme for university representation in Great Britain contained in a schedule to the Reform Bill proposes to increase the number of university representatives in Great Britain from seven to ten, and that three members should be allotted to the Scottish universities voting as a single constituency. The voting would be on the proportional representation system, each elector having one transferable vote. The Business Committee of the General Council of the University of Glasgow has put forward a scheme under which there would be three constituencies, each returning one member—namely, Edinburgh, with 12,654 voters on the register at January 1st, 1915; Glasgow with 9,307, and Aberdeen and St. Andrews with 6,965 (Aberdeen 5,000, St. Andrews 1,965).

UNIVERSITY OF EDINBURGH.

AT a meeting of the University Court on October 22nd it was reported that £2,000 had been received towards the fund of £4,000 offered to the University by some friends of women's education to help to meet the expenses incurred in the introduction of women students to classes in the faculty of medicine.

At the half-yearly meeting of the General Council of the University on October 26th it was reported that 5,000 members of the University were now serving in the forces, and 368 were known to have been killed or died. It was resolved that a Chair in German should be established after the war provided that an endowment sufficient to yield an income of £800 was obtained. The Principal expressed a strong opinion that no professor of any subject in the University should be asked to accept a salary of less than £800 a year. The Finance Committee reported that the number of women students had increased this year as compared with last, and added that it was significant that the increase was in the faculties of science and medicine.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the comitia was held on October 25th, the President, Sir Frederick Taylor, Bt., occupying the chair.

Members.

The following candidates having passed the required examination were admitted as members:

J. J. Conybeare, M.B. Oxon, D. E. Fenwick, M.B. New Zeal., J. G. Greenfield, M.B. Edin., Helen M. M. Mackay, M.D. Lond., L.R.C.P., W. S. Sharpe, M.D. Durh., L.R.C.P., J. C. Tull, M.D. McGill.

Licences.

Licences to practise physic were granted to 89 candidates who had conformed to the by-laws and regulations and passed the required examinations.

The Preliminary Examination.

A report from the committee of management recommending modification of the regulations for the preliminary examination was further considered and adopted. The chief difference between the new regulations and those previously in force is the omission of Latin as a compulsory subject.

Recognition of Schools.

King Edward VII Grammar School, Southampton, and Lancing College were added to the list of institutions recognized by the committee of management in chemistry and physics, and Bootham School, York, was recognized for instruction in biology also.

The Committee of Reference.

The President reported on the proceedings of the Committee of Reference under the Military Service Acts during the past six months.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

FINAL EXAMINATION.—R. Pollok, A. Bissemer, H. Wildeboer, J. B. Minford, F. G. Pailthorpe, G. N. Groves, C. C. Magee, Agnes E. Keen, H. G. Smith, B. M. Lyman, R. Quesada-Jimenez, I. Davies, L. P. Samarasingha, C. V. Samwell, Phoebe Foott, R. D. Howat, D. McK. Black, G. P. de Silva, C. D. Pullan, *Medicine*: J. L. West, Arukatti Patubendigo Frederick Abey-suriya. *Surgery*: A. Parker, W. G. Wilson. *Midwifery*: S. A. Faulkner, Indrarayana Borrah, A. E. W. Sandelson, Arukatti Patubendigo Frederick Abey-suriya, C. R. C. Moon, A. P. McLeod, A. Parker. *Medical Jurisprudence*: H. W. Howatson, Lizzie R. Clark, T. H. J. Douglas, D. A. Walpole, C. E. S. Ruchman, J. Boyd, C. R. C. Moon.

The following have been admitted Diplomates in Public Health: Annie R. McKail, Ella F. Pringle, J. L. Owen.

Medical News.

THE Minister of National Service has appointed Mr. J. Seymour Lloyd, C.M.G., a member of the Parliamentary Bar, to be Director-General of Recruiting and the Rev. J. R. McLean, a minister of the Presbyterian Church, to be Deputy Director-General.

DR. WOODS HUTCHINSON began a course of three public lectures, arranged by the Chadwick trustees, on "The part of hygiene in the European war," on Wednesday last. The remaining lectures will be given on Thursday, November 8th, and Wednesday, November 14th, at 3.30 p.m.

THE demonstrations of specimens of inflammation and gunshot injuries, to be given at the Royal College of Surgeons of England by the Pathological Curator, Professor S. G. Shattock, F.R.S., on Mondays, Nov. 5th, 12th, and 19th, at 5 p.m., will be open to medical students and practitioners; first aid and ambulance students desiring to attend will also be admitted.

THE French public has long been asking why, if the British soldiers in France could have periodically a bath and change, their own could not. After the commanders of units, the engineers whose duty it was to supply huts and pipes and taps, and the commissariat who controlled the water, soap, and linen, had fumbled with the matter for months which ran on into years, somebody had the bright idea that as the medical department was responsible for the health of the troops it would be logical to hand the bath question over to it. Within a very short time each division was provided with a *section d'hygiène corporelle*. Each possesses a movable hut containing three rooms, the first an undressing room, the second a douche room, and the third a dressing room. There is a disinfectant, a drying hut, and three store tents. The staff consists of three non-commissioned officers, three stokers, and ten orderlies, including a hairdresser and pedicurist. When the man reaches the dressing room he finds clean underclothing ready for him and his uniform dried and stoved. The men pass through at the rate of forty in twenty-five minutes.

Letters, Notes, and Answers.

Authors desiring reprints of their articles published in the **BRITISH MEDICAL JOURNAL** are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the **BRITISH MEDICAL ASSOCIATION** and **JOURNAL** are:

1. **EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Aitology, Westrand, London*; telephone, 2631, Gerrard.
 2. **FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
 3. **MEDICAL SECRETARY**, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the **British Medical Association** is 16, South Frederick Street, Dublin.
- The address of the **Central Medical War Committee** for England and Wales is 429, Strand, London, W.C.2; that of the **Reference Committee of the Royal Colleges in London** is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the **Scottish Medical Service Emergency Committee** is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

M.D. desires to find a print of a full-length figure of St. Luke, suitable for the centre light of a painted window.

MR. CHARLES H. GREENWOOD, F.R.C.S. (Ripon), asks for recent experience in the use of metallic colloids in the treatment of cancer.

INCOME TAX.

A TERRITORIAL MEDICAL OFFICER inquires whether he can deduct two-thirds of the rent of his house, which he "used" for the purpose of his profession. It has not been used as such since August 4th, 1914.

"* We fear not. If the house is no longer used for professional purposes the proportion to be deducted as representing the part occupied for the purpose of the profession is apparently nil. The only argument in favour of the allowance that occurs to us is that the house is in fact serving the purpose of keeping our correspondent's name before his former clients, but only a very small proportion of the rent could in any case be attributed to that purpose."

LETTERS, NOTES, ETC.

SALE OF COCAINE ON PRESCRIPTION.

A CASE which, it was stated, the Home Office authorities regarded as being one of considerable public importance came before Mr. Denman, the Marlborough Street magistrate, on October 26th, when Mr. William Cooper, of the firm of Roach, Pope and Son, chemists, of St. James's Street, was summoned for selling cocaine in a manner which contravened the Defence of the Realm regulations.

MR. H. G. MUSKETT, the prosecuting solicitor, read the regulations as consolidated to September 30th of the present year, and said that the material conditions governing the sale of cocaine were (a) that it must be supplied on and in accordance with a written prescription from a duly qualified medical practitioner, and dispensed by a legally authorized person; (b) that the prescription must be dated and signed by the practitioner with his full name, address, and qualifications, must be marked "Not to be repeated," and must specify the total amount to be supplied; (c) that the cocaine must not be supplied more than once on the same prescription, and (d) that the prescription must be marked with the date on which it was dispensed. It was also required that the prescription should be kept upon the premises of the dispenser and be open to inspection by an authorized person. The summonses in this case related to two sets of incidents occurring in June and August last. It was found on visiting the defendant's premises that the records of the sales were kept in a manner which did not fulfil the requirements of the regulations, but the more important matter related to the form of the prescriptions. The first of the two prescriptions failed to comply in every material respect with the regulations just referred to. It was initialed only by the doctor; it did not bear his name, address, or qualifications, nor the words "Not to be repeated." He did not suggest that the prescription, apart from its form, was improper, but a person having only the slightest knowledge of chemistry and of the properties of the drug might have given it. The second case related to a 2 per cent. solution of atropine and cocaine. In this case the record again was faulty, and on inquiring for the prescription the Home Office official was told that there had been no written prescription, but that the drug had been dispensed upon a telephone message from the doctor; subsequently, however, the defendant discovered a written prescription, which was in order in that it bore the name, address, and qualifications of the doctor, but it did not bear the address of the person for whom the drug was prescribed, and it fell short of what was required under the regulations by omitting the date on which it was in fact prescribed, and the words "Not to be repeated" were absent from the face of the document. It was thought right to bring this prosecution with a view to driving home the importance of these regulations.

MR. C. H. KIRBY, for the defence, said that the two main provisions of the regulations were, first, that the cocaine should not be dispensed except upon a doctor's prescription, and, in the second place, that steps should be taken to prevent a person getting the prescription made up oftener than was authorized by the doctor—that is to say, more than once on the same prescription. These regulations had been complied with by the defendant, who did, in fact, supply the preparation in both cases upon a doctor's prescription and himself retained the prescription. It was true that the prescriptions themselves were defective, but—although this did not relieve the chemist of responsibility—the person mainly responsible for that was surely the doctor, and in neither instance was the doctor summoned. In the case of the prescription bearing only the doctor's initials, the doctor was well known to the defendant. The prescription was not marked, "Not to be repeated," but the defendant effectively prevented it from being repeated by retaining it in his possession. The quantity supplied was one fluid drachm only of the oil of cocaine, a preparation containing castor oil. The cocaine was supplied in so small a quantity and in such a form that it was very unlikely that anybody would consume it. In the second case the prescription also was retained by the chemist, so that the omission of the words "Not to be repeated" did not seem to be of more than technical importance. The address of the purchaser was not given but was easily ascertainable from the doctor, whose name and address in this case were on the prescription, and whom the defendant knew well. The defendant had committed technical irregularities, in excuse for which he pleaded pressure owing to shortage of staff. With regard to the incident of the telephone, a doctor would occasionally telephone what he was prescribing, and ask for it to be ready when the patient called; the drugs were not handed out until the prescriptions were received.

The magistrate said that nobody could doubt the importance of the regulations being strictly adhered to, and he for one had had it brought home to him very closely during the last year. In this case there had obviously been negligence and carelessness. Chemists more than any other class of persons should make themselves acquainted with every regulation, because they were placed in a position in which non-compliance might result in grave harm. He fined the defendant £25 on each of the two cases, and costs totalling to £4 10s.

A TOO-PUNGENT MOUTH-WASH.

M.D. LOND. writes: I should like to be allowed to furnish my testimony as to the great efficacy of thymol solution as a mouth and teeth wash. I formerly was much troubled with the formation of tartar and a tendency to pyorrhoea alveolaris. My dentist, a well-qualified man, used many applications, including potassium permanganate, hydrogen peroxide, iodine, etc., without effecting a cure. From the time the first paper on the subject appeared in the **JOURNAL** I have used the thymol solution night and morning, and all trouble has long passed away. It is most simple to use, and quite inexpensive. I simply put about a drachm of the thymol crystals at the bottom of an 8-oz. bottle, and keep filled up with cold water. I take a mouthful and stir it about round the teeth with a soft toothbrush. Some of the original drachm of thymol is still at the bottom of the bottle after three months' use (cost 6d.), showing the extreme dilution of the saturated solution. I have never experienced any burning or unpleasant effects, nor have any of the many persons to whom I have introduced this simple but most effective remedy. All speak in the highest terms of it, including the above-mentioned dentist, who wrote to me a letter of thanks for drawing his attention to it. Probably there may be an impure thymol occasionally on the market, which may have some acrid property. The pure thymol occurs in colourless crystals.

The saving of expense, too, is great. People who had been spending perhaps pounds on mouth-washes and tooth pastes can now with a minimum of trouble accomplish much more effectively their purpose at a purely nominal expense. If introduced among the poor, it would, I think, create a revolution in the condition of the teeth of poor children.

HAEMATEMESIS AND MELÆNA NEONATORUM.

DR. D. OWEN WILLIAMS (Glandyfi) writes: The treatment of the case described by Dr. Marriott reminds me that the late Dr. Dobie of Chester said that he had treated successfully a baby suffering from melæna, soon after birth, by simply giving it a few drops of liquid extract of ergot. The baby has long ago attained manhood.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5
Each additional line	0 8
A whole column	3 10
A page	10 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the **British Medical Association** at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

The Bradshaw Lecture

ON

MISPLACED AND MISSING ORGANS.

DELIVERED BEFORE THE ROYAL COLLEGE OF SURGEONS
OF ENGLAND, NOVEMBER 8th, 1917.

BY

SIR JOHN BLAND-SUTTON, F.R.C.S.,
SURGEON TO THE MIDDLESEX HOSPITAL.

*Thou knowest not . . . how the bones do grow in the womb
of her that is with child.*—Eccles. XI, 5.

THE monotony of order and regularity is impressed on us early in the study of anatomy. The eagerness with which students draw the attention of demonstrators to abnormalities they find, when dissecting, is notorious. Constancy of position is not a virtue of viscera; but it is amazing that in ninety and nine bodies out of a hundred the abdominal organs fall into their proper places during fetal life.

Until the main features of the development of animals were closely investigated, variations in the position of the

detected in radiographs of the spine, and it is often associated with spina bifida. Half-vertebrae have been found in fishes, snakes, calves and rabbits. Embryology has disclosed many secrets concerning missing organs: some parts true to the impress of heredity appear in the embryo and disappear with the gradual perfection of the fetus. Parker, studying the development of the green turtle, noticed that the embryo possessed ten more somatomes than were represented by vertebrae in the adult. Seven were suppressed in the neck and three in the tail. This suggests for turtles ancestors with longer necks and tails than existing forms. There can be no doubt that if turtles were dissected as thoroughly as they are made into soup many examples of supernumerary cervical vertebrae would be found among them, in spite of the specialization that exists in the vertebral elements of the Chelonian neck. The best known example of a missing vertebra occurs in the sea-cow or manatee. As all students of human osteology know, this mammal has six, instead of seven, cervical vertebrae. Kükenthal discovered another curious feature in this weird mammal: the fetal manatee has a thick coating of rudimentary hair, but the skin of the adult animal is, like that of the whale, almost hairless. The abundance of hair on the fetal manatee indicates that manatees had ancestors as furry as seals. Long ago, John Hunter noted that whales and sea-cows, mammals living entirely in the water, could derive no advantage from hair, but they have an immense quantity of subcutaneous fat which is a worse conductor of heat than water. When the ancestors of the manatee took to water they lost their hair but gained fat. Embryology furnishes evidence concerning kinship and descent. Our thoughts may be turned in this direction when we eat

FIG. 1.—Larva of the sole, brill, and flounder.
(J. T. Cunningham.)

FIG. 2.—A calf of 2½ months with its heart in the dewrap.

viscera aroused curiosity, and must have been as ill understood as the reasons for the bilateral symmetry of the body. In the case of bilateral organs, such as the eyes, ears, teeth, kidneys, ovaries, and bones of the limbs, as well as the opposite halves of median organs like the brain, tongue, bladder, and uterus, the symmetry is astounding. Although there are minor variations in bilateral organs, the general likeness in shape is so close that the ability to distinguish between right organs and left organs is an examination test for estimating the diligence of students in practical anatomy. The bone that fascinated me most is the stapes. It is the smallest bone in the skeleton, and thoroughly justifies its name. The right and the left stapes are so like each other that it is difficult to tell one from the other. They are as nearly alike as a pair of stirrups. He who doubts this should examine the unique collection of auditory ossicles in the Museum.

Not the least interesting feature of anatomical research is the detection of additional skeletal elements. It is not uncommon to find an extra vertebra in the lumbar set, or in the coccyx. Excess in number is no disadvantage, but occasionally half a vertebra is missing. When this happens it causes tilting of the spine. A study of available specimens shows that this anomaly may occur in any region of the spinal column. Such deficiency can be

a flat-fish. Sole, plaice, brill, dab, flounder, and halibut when first hatched are symmetrical and transparent; they have an eye on each side and swim in a vertical position. Later the fish flattens, and the facial portion of the skull twists in such a way as to bring the eyes to the upper surface. The hinder part of the skull that contains the brain does not share in the twist. Sometimes a sole is found with an eye on the white or "blind" side. Holt described an example in 1894. The larva of a flat-fish, so transparent when alive, is only rendered visible by the metallic brilliancy of the eyes, which shine through the transparent tissues like metal beads (J. T. Cunningham). The alteration in the position of the eye influences the mode in which the little fish swims. For instance, in the flounder (Fig. 1) the left eye projects above the edge of the head on the left side. The fish in this condition swims on its edge, slightly inclined to the left side. During the whole of the change, from a bilaterally symmetrical to a flat fish, the inclination from the vertical in swimming is proportional to the degree of asymmetry of the eyes.

A CERVICAL HEART.

Many mammalian organs migrate during embryonic and fetal life, and some of the changes in their position are as extraordinary as those of the eye of flat-fishes. Early in

the study of human anatomy this matter comes forcibly to our notice when we study the recurrent course of the inferior laryngeal nerve, and realize that its unusual course is due to the transit of the heart from throat to thorax. There is nothing quite so fascinating as watching the pulsating embryonic heart of a chick lying clear of the body cavity, then to trace its gradual enclosure, translation, and final imprisonment by the completion of the walls of the body cavity. Occasionally the heart fails to reach its normal place, and is detained in the neck, an embryological accident not uncommon in calves. The clinical features of such an anomaly are striking. A calf (Fig. 2) was born near Montrejeau (1902), and its owner sought the advice of Bourdelle on account of a globular pulsating swelling in its dewlap. The swelling, which was as big as a cocoon, became soft and flaccid, then hardened suddenly, and sensibly diminished in volume. These changes happened regularly seventy times per minute synchronously with the pulsation in the arteries. There was no difficulty in recognizing the supposed tumour as the heart. The calf, which did not appear to suffer inconvenience from the anomalous position of its heart, was killed in order that a complete anatomical examination could be made. The details are given with great care in the *Revue Vétérinaire*, 1902. The thoracic cavity was much smaller than usual, partly due to an abnormally forward position of the diaphragm, which was also displaced by an unusually large liver. A cervical heart is a rare anomaly, but I will now describe something rarer.

AN INTRATHORACIC STOMACH.

The diaphragm is a muscle peculiar to mammals, and the long course of the phrenic nerves arouses curiosity.

FIG. 3.—The thoracic surface of the diaphragm, showing the position of the infracardiac bursa in a human fetus. (Broman.)

In the embryo, the thorax and abdomen form a common cavity, as in amphibians and reptiles. This pleuro-peritoneal cavity is divided by the diaphragm into thoracic and abdominal cavities. The precise manner in which the diaphragm arises is not easily appreciable, and this muscular septum is liable to some gross defects. Deficiency of the left half of the diaphragm has often been recorded, and few pathological museums are without an example.

A child with a partial diaphragmatic hernia may survive its birth and attain adult life, but in the majority of patients with diaphragmatic hernia that come under the observation of surgeons the lesion is traumatic. Imperfections of the diaphragm allow the intestines and stomach to intrude into the thoracic cavity, and without the help of x rays it would be difficult to diagnose such a condition with certainty. To-day the stomach requires a section in textbooks of surgery to itself, and anomalies in the position of the stomach are of practical interest. I had an opportunity (1917) of studying an intrathoracic stomach presenting unusual features. A spinster, aged 26, complained of gastric disturbance of such severity as justified an examination with x rays and an opaque meal. The radiographs disclosed the shadow of a body above the diaphragm, displacing the heart to the left. Two radiographers of experience agreed that the intrathoracic shadow represented a stomach lying above the diaphragm. The patient's discomfort justified operation. The parts were exposed by a median supra-umbilical

incision, but no stomach was visible. Then I found a cleft in the diaphragm on the right side of the oesophagus from which small intestine emerged. On introducing my finger I found the stomach lying in a pouch extending into the thorax. I withdrew the stomach; it was of normal size, but had very thick walls, and on being released at once slipped out of sight into the pouch. The limits of the pouch were clearly indicated on the radiographs. The patient recovered from the operation, but suffers occasional discomfort and attacks of vomiting. Her digestive disturbances have not been relieved, nor aggravated by the interference. The pouch occupied by this vagrant stomach has an embryologic history. The region of the abdomen known as the lesser bag of the peritoneum is, for the Swedish anatomist Broman, the omental bursa. In the embryo it extends into the thorax on the right of the oesophagus. In the fetus a small pouch exists in this situation—the infracardiac bursa. In adults it may be detected as a narrow slit (Fig. 3). Man, in common with other members of his class, has two pleural cavities; some monkeys possess a third that lodges the odd or azygous

FIG. 4.—Intestinal tract of a human embryo 6 cm. long. The liver has been removed. (Broman.)

lobe of the right lung; Simpson found one in a man (1807). The infracardiac bursa of the fetus represents the third pleural cavity. It was a cave in my patient and hid the stomach.

THE UNDESCENDED CAECUM.

Under normal conditions the caecum occupies the right iliac fossa, and in many, especially women, it dips into the right half of the pelvis. The changes which take place in the disposition of the intestines, great and small, during fetal life are well known to anatomists. These movements lead to and end in the complicated arrangement of the peritoneal folds that cause despair to the novice in human anatomy.

In a large number of mammals the whole intestinal tract from the middle of the duodenum to the end of the colon is slung on a common mesentery. This is the arrangement found in the human embryo; it occasionally persists in adults, and leads to some remarkable displacements of the caecum that cause a very fatal form of intestinal obstruction. In the early embryo the caecum does not exceed in circumference a contiguous coil of ileum; even at this stage it is defined by the vermiform appendix (Fig. 4) and lies in contact with the under surface of the liver. Gradually enlarging, it descends to the normal position in the right iliac fossa. It is a common condition to find the caecum completely invested with peritoneum, and almost as mobile as a small ovarian cyst. Occasionally the caecum is retained in the fetal position, immediately under the liver.

The alarming frequency of septic disease of the vermiform appendix leads surgeons to study keenly variations in the positions of the caecum and anomalies connected with its descent, for these determine the final situation of the appendix. Experience in the operating theatre teaches surgeons that the vermiform appendix may lie in any position between the under surface of the liver and the floor of the pelvis. I have on several occasions found its tip touching the gall bladder. When the appendix is retrocaecal, it often lies in contact with the kidney. I have carefully studied the retrocaecal appendix, not only on account of the difficulty that sometimes attends the diagnosis of appendicitis when the appendix lies behind the caecum, but also to ascertain the causes which lead to this position. It admits, I think, of the following simple explanation. In many of the cases in which the appendix lies vertically behind the caecum its tip is firmly fixed

FIG. 5.—Pelvic kidney; from a man.

near the liver. Thus it happens, if the tip of the fetal appendix is anchored, it cannot descend with the caecum into the iliac fossa, but the descending caecum gradually lengthens the appendix. This will explain the fact, familiar to surgeons, that a retrocaecal appendix is often abnormally long, straight, and lacks a mesentery. Occasionally I have found the tip of a retrocaecal appendix so firmly fixed to the peritoneum in the loin that the caecum, though it has descended into the iliac fossa, has had its blind end turned upwards to the liver. In such a case the caecum is suspended by the appendix. The mechanism by which the caecum migrates is associated with that determining the descent of the testes and the ovaries. Non-descent of the sexual glands is often associated with an undescended caecum, and those ill understood movements, or readjustments, of the peritoneum that occur at a late period of fetal life.

THE PELVIC KIDNEY.

Some of the changes in the position of abdominal viscera are almost romantic. The extraordinary movements culminating in the descent and extrusion of the

testicles were detected by Haller in 1755; John Hunter described the process thoroughly in 1762, and left little for subsequent anatomists to discover. It is not generally appreciated that the kidneys undergo a marked translation during fetal life. Many years ago, whilst making a *post-mortem* examination of a man, I found one of his kidneys in the hollow of the sacrum (Fig. 5); it received its blood supply from the right and the left common iliac arteries. I have seen a kidney in this situation in a woman; it was regarded before operation as a distended Fallopian tube. When the pelvic organs were exposed in the course of the operation a curious set of anomalies appeared. The uterus was of the unicorn variety and had a right ovary, tube, and broad ligament. The left side was smooth and round, and lacked appendages of every kind, including the round ligament. The right kidney was normal in position and shape. This woman conceived after the operation and was delivered without difficulty, in spite of the kidney in the hollow of the sacrum.

A pelvic kidney may become hydronephrotic, and it has happened that a gynaecologist, unaware of this anomaly, removed such an organ under the impression that it was an ovarian cyst. The retention of a kidney in the hollow of the sacrum admits of an explanation.

FIG. 6.—Diagrams to show the varying relations of the adrenal and kidney in the human embryo. (Broman.)

The position of the kidney in the human embryo is influenced by the size of the adrenal. During intrauterine life the adrenals are large and conspicuous. In the first half of the second month the adrenal is double the size of the kidney and the two organs are widely separated (Fig. 6, A). Then the kidney grows faster than the adrenal. At the end of the second month they are equal in size, and subsequently the kidney becomes the more conspicuous organ. The relationship of the kidney to the iliac arteries (Fig. 6, B) in the embryo explains the occasional occurrence of a pelvic kidney in, or near, the pelvis.

The close proximity of the kidneys in the pelvic region of the embryo helps us to understand the origin of the common anomaly known as horseshoe kidney, in which the two kidneys are more or less intimately joined by their lower poles, and the ureters usually lie in front of the renal isthmus. In one example I have seen both halves of such a kidney hydronephrotic and the isthmus passed across the pelvis below the promontory of the sacrum.

The large size of the adrenal in the human embryo is due to the preponderance of the cortex over the medullary portion (T. R. Elliott), and this is in some subtle way,

correlated with the development of the cerebrum. The hypertrophy of the adrenal cortex in embryonic life is a feature peculiar to human fetuses, and if the cerebrum fails to develop, as in anencephalous human fetuses, the proportions of cortex and medulla are like those of other mammals. It is said that Morgagni (1723) knew of this

FIG. 7.—Head of a mare with a sinus leading to some mastoid teeth. The drooping lip shows palsy of the facial nerve. The teeth are shown below, two in section. (From *Tumours*, 6th ed.)

correlation between the cerebrum and the adrenals, but I have failed to find the statement in his Letters.

Although I have collected half a score examples of pelvic kidneys in men and women I have failed to obtain any evidence of pelvic kidneys in other mammals. This may be used as additional evidence that the caudal displacement of the kidney in the human embryo is due to the predominance of the adrenal cortex.

SPECIFIC ORGAN-FORMING SUBSTANCES.

The correlation between the cortex of the adrenal and the cerebrum leads us to the consideration of what are known as specific organ-forming substances. This may be exemplified by an experiment on the developing eye. The chief features in the formation of the eye of a vertebrate animal are well known. The essential nervous elements of such an eye are furnished by the optic vesicle, an outgrowth from the brain. The lens begins as a circumscribed thickening (or plakode) of the surface epiblast, which is received into the hollow formed by the invagination of the optic vesicle. Lewis, in the course of some remarkable experiments performed on tadpoles, cut off the optic vesicle, and pushed the amputated organ under the skin to a new place; no lens was formed in the normal position, but a lens-like structure developed from the skin situated over the optic vesicle.

This specific organ-forming influence can be studied in the poultry yard. Hens have only one ovary and oviduct

FIG. 8.—Ear of sheep with an accessory ostium and tooth.

—the left. The right ovary and duct are missing. Often the absent oviduct is represented by a vestige attached to the cloaca. In winter the left ovary is small and insignificant, and the oviduct a mere thread. In spring the ovary is the most conspicuous organ in the abdomen, and the oviduct becomes enlarged, convoluted, and resembles intestine in size and appearance. It is reasonable to believe that some specific secretion, formed in the ovary, stimulates growth and tissue formation in the oviduct, and the vestigial condition of the right oviduct of birds is correlated with the absence of the corresponding ovary. The influence of glandular activity on tissue-production is remarkable. No one has seen an eye without an optic nerve, or a gall bladder without a liver, a ureter without a kidney, or a uterus without a sexual gland. I have seen and described a uterus in a boy, but there were testes associated with it. There is a side issue connected with the missing ovary in birds that is worth mention. From very ancient times men and women have believed that the right ovary furnishes boys and the left ovary girls. Many medical men believe it to-day; the tradition is deeply rooted; it has no foundation. As hens have only one ovary, the left, those who believe this tradition must tell us "where the cocks come from" (Blackler).

MASTOID TEETH.

Thirty-five years ago my curiosity was aroused by some strange teeth lodged in the mastoid region of a horse's skull. The specimen is preserved in the museum of the Veterinary College at Alfort, near Paris. The horse was dissected in the college, and the teeth were described by Professor Goubaux in 1849. On the skull is written, "Supernumerary molars in the temporal region of a horse." I re-examined this skull and some other examples of mastoid teeth when I revisited the museum in 1917. From the day that I first examined these misplaced teeth, impacted in the mastoid portion of the temporal bone, my interest in them remained unabated. Teeth in this situation are not novelties. I have examined a score of such specimens. The presence of mastoid teeth is indicated by a sinus at the base of the ear (Fig. 7), from which purulent and mucous fluid issues. This leads to an examination and the detection of the teeth. Sometimes one tooth is present, lodged in the attic of the tympanum, a fact that has given colour to the erroneous impression that the sinus and the misplaced tooth arise from imperfect closure of the branchial pouch from which the tympanum is derived. Occasionally several teeth are present; they are invariably ill-formed, and two or more teeth may be blended, forming a mass resembling an odontome enclosed in a bony capsule embedded in the mastoid region of the skull. Such dental conglomerates contain enamel, dentine, and cementum in a complex jumble. The dental mass sometimes bulges into the cranial cavity, and if the sinus becomes septic the horse dies from meningitis. The facial nerve is sometimes involved in the Fallopian aqueduct, and leads to facial palsy.

Veterinary surgeons remove mastoid teeth in a summary manner. They enlarge the sinus, ascertain the position of the tooth, and remove it either with forceps or a chisel and mallet. The cavity is stuffed with antiseptic gauze and allowed to heal.

In 1890 I obtained some new light on these curious teeth. Dr. John Evans of Aberdare sent me a sheep's

at a meeting of the Pathological Society, London, caused comment and vague speculation. Many years elapsed before I got any clear light on this specimen, and the clue gradually came from a study of double-headed animals.

BICEPHALOUS ANIMALS.

The teratological collection in this museum is the finest in the world. It was founded by John Hunter, who took a keen interest in monsters, not from curiosity, but as part of a great scheme showing the various phases of life. This collection includes monstrous beans, cucumbers, and apples; eels and salmon, carp and shark, crabs and lobsters, lizards and snakes, sparrows and pigeons, chicks and ducklings, kittens and pups, lions and lambs, hares and rabbits, sheep and rams, cows and calves, monkeys and men. Many are so misshapen that we may, with Job, ask who gendered them. The most extraordinary specimen is the skull of a double-headed child obtained from Bengal (Fig. 9). Mr. Shattock regards it as the most wonderful specimen in the museum, and he is a competent judge. The remarkable history of the unfortunate child is given at length in the catalogue.

Hunter noted that some malformations are common in certain genera of animals. Double-headed horses, oxen, and sheep are common. During the last thirty years I have examined a hundred specimens in museums, dissecting rooms, and penny shows.

In 1877 Gurlt published some observations on malformations among domesticated animals and figured the head of a lamb with incisors lodged in a diminutive but unmistakable mandible, and a tongue of corresponding size. The mandible, teeth, and tongue were associated with

FIG. 9.—The skulls of a double-headed child, aged 4 years. (Museum, Royal College of Surgeons.)

FIG. 10.—Head of a cross-bred Devon ox with an accessory head attached to its throat. A cane passed through the accessory mouth entered the normal pharynx.

ear (Fig. 8) with a fistula corresponding in situation with the sinus in the mare. Near the orifice, and associated with it, there is an incisor tooth, in shape indistinguishable from the normal incisor of a lamb. The neck of the tooth is surrounded with mucous membrane (gum), and its root occupies a bony socket; the whole is lodged in a fold of skin beset with black papillae. This fold of skin resembles in every feature the lower lip of a lamb. The rest of the head had been lost, probably eaten. The ear, when shown

FIG. 11.—Calf's skull with an accessory skull attached in the mastoid region. (Museum, Royal College of Surgeons.)

a fistula opening into the normal pharynx of the lamb. When the animal drank, some of the fluid escaped through the fistula. A similar condition is shown in Fig. 10, except that the subject is a cow of the Devon breed. This cow

was exhibited in a travelling show. Attached to the neck is a mandible with teeth and tongue; an orifice associated with the tongue led into the cow's pharynx. A study of this and similar recorded examples leads me to endorse Gurlt's opinion, that these cervical teeth, mandible, and tongue are remnants of an accessory head and the fistula represents the mouth of the rudimentary head. The museum contains some admirable examples of bisphenous skulls of calves. These double skulls are remarkable from the constancy with which they are confined in the mastoid region. A useful specimen shows a well-formed skull, with one less perfectly developed, firmly fused to it in the mastoid region (Fig. 11).

The critical study of a large number of such skulls leaves no escape from the conclusion that mastoid teeth and an auricular sinus in horses, like a cervical ostium and teeth in a sheep or an ox, are remnants of an accessory or parasitic head. *Mastoid teeth are memorials of a lost individual.*

Teeth are conspicuous and easily recognized. They develop and calcify during fetal life into resisting structures and serve as useful signs. This is illustrated by a monstrous pig I dissected and added to the Teratological Gallery in 1888. The pig in external appearance is double in all parts except the head and neck. I made a complete examination of the head and found a pair of fused maxillae impacted between the normal jaws, and felt convinced that an accessory mandible existed somewhere about the pig's head. At last I found a rudimentary parasitic mandible, with teeth hanging like a polypus in the pharynx, and attached by a narrow pedicle to the base of the skull. It is the oddest example of a misplaced organ that has come under my notice.

If Professor Keith accepts my explanation of the origin of mastoid teeth, he will realize that they are misplaced in the Dental Collection. Their proper place in this museum is the Teratological Gallery.

THE MICROSCOPIC EXAMINATION OF THE BRAINS OF TWO MEN DEAD OF COMMOTIO CEREBRI (SHELL SHOCK) WITHOUT VISIBLE EXTERNAL INJURY.*

[WITH SPECIAL PLATE.]

BY

F. W. MOTT, M.D., LL.D., F.R.S., F.R.C.P.,

PATHOLOGIST TO THE LONDON COUNTY COUNCIL ASYLUMS, MAUDSLEY
HOSPITAL, DENMARK HILL.

The examination of the brains of two cases of death from shell shock without visible injury and without punctate haemorrhages indicative of gas poisoning is of interest for several reasons. So far as I know, it is the first description that has been given which serves to explain (1) sudden death in shell shock, and (2) the clinical symptoms which persist for some time after the commotion of the brain in non-fatal cases.

I am indebted to Lieut.-Colonel T. R. Elliott and Professor Arthur Keith for sending me the brains, and to the officers whose names are mentioned for the clinical notes and the notes of the *post-mortem* examination.

CASE I. Clinical Notes.

In this case the man developed, according to a note furnished by Captain J. London, a degree of nervousness on the *Somme* which he never lost, but was able to control for six months. Later he was in an area which was subjected to an intense bombardment, during which, as far as can be ascertained, no gas shells were used. This lasted about four hours (February 22nd, 4 p.m. to 8 p.m.). Although he remarked to another man that he "could not stand it much longer," he did not give way until the following day, twelve hours later, when perhaps six shells came over (February 23rd, 8 a.m.).

He was not buried nor gassed. One shell burst just behind his dug-out—namely, 10 ft. away—in the morning, but many must have been as near the previous day. Early symptoms were tremors and general depression. The later symptoms (February 22nd) were coarse tremors of the limbs, crying (February 23rd), inability to walk or do anything. He would not answer questions—very like the hysterical manifestations of melancholia. The pupils were dilated. Captain London states

that he was rather busy with some wounded at the time, and did not make a detailed examination.

A note by Captain Francis A. Duffield, R.A.M.C. (S.R.), states that the man was admitted to the field ambulance in the evening in a state of acute mania, shouting "Keep them back, keep them back." He was quite uncontrollable and quite impossible to examine. He was quieted with morphine and chloroform, and got better and slept well all night. In a later note Lieut.-Colonel J. F. Crombie, in command of the field ambulance, stated that the patient had at least two hypodermic injections of morphine while in the ambulance. Next morning he woke up apparently well, and suddenly died.

Necropsy.

The following is a report by Captain A. Stokes, R.A.M.C. (Mobile Laboratory), on the *post-mortem* examination, made on the afternoon of the day of death:

There were no marks of external violence on the body other than some small scratches on the anterior chest wall.

Thorax.—The lungs were oedematous, and in the substance of the lower lobe of the left lung there was a considerable haemorrhage. The right lung, except for oedema, was normal.

Heart.—Enlarged, and the right side dilated. The muscle was good, and there was no valvular lesion.

Abdominal Cavity.—Normal. There was no pathological change in the stomach, oesophagus, intestine, or great intestine. The liver was normal in size, and was somewhat congested. The spleen was normal. The kidneys were small, but showed no gross change. The urine contained neither sugar nor albumin.

Skull.—There was a slight bruise on the scalp, in the frontal region. The brain was extremely congested, and on each side of every superficial vessel there was an ecchymosis. Therewere a number of minute punctiform haemorrhages at the terminations of the smallest vessels on the surface of the brain. The whole brain was soft but not markedly oedematous. The cerebro-spinal fluid appeared to be blood-tinged. There was considerable ecchymosis on each side of the great sinuses of the skull. There was no large haemorrhage found, and no small intracerebral petechiae. There was no gross lesion of the viscera, which would have been a cause of death; but though I have never seen a *post-mortem* examination on a man who has died of "shell shock," I consider the condition of the brain is consistent with that diagnosis.

MICROSCOPIC EXAMINATION OF THE BRAIN OF CASE I.

The brain had been preserved in Kaiserling's fluid, and it was not in very good condition, but seeing that it was placed in this fluid less than twelve hours after death, it is probable that the portions examined yielded satisfactory material for microscopic investigation.

The portions of brain selected were prepared for section by the paraffin method of serial sections. The dyes used to stain the sections were as follows: (1) Haematoxylin and eosin, (2) Van Gieson, (3) thionin, (4) polychrome and eosin. The sections were 5 μ in thickness and were mounted, after staining, in Canada balsam.

Cerebrum: Top of Ascending Frontal Convolution—Leg Area.—The veins are congested both in the meninges and in the substance of the grey and white matter. There is subpial haemorrhage here and there owing to rupture of the dilated congested veins. There are no punctate haemorrhages observable. The perivascular spaces of the arterioles, capillaries, and venules are dilated, also the perineuronal spaces are distinctly seen, some being apparently connected with the perivascular spaces. In some of the sections empty collapsed vessels can be discerned in places. The general appearance suggests deficiency of blood in the arteries and capillaries, with engorgement of the venous system. A condition very similar to that observed in experimental anaemia in animals produced by ligation of both carotids and vertebrals. There is some degree of chromatolysis of the cells. The Betz cells are the easiest, on account of their size, to recognize this change, and Fig. 1 shows the early chromatolysis of these psychomotor neurones.

The pole of the first frontal shows marked congestion of the vessels and some subpial haemorrhage from dilated congested veins. Many of the arterioles and capillaries are empty and collapsed, and there is the same appearance of dilatation of the perivascular sheaths and perineuronal spaces. The pyramidal cells also show early chromatolytic changes.

Internal Capsule.—There is general congestion of veins, and the small vessels appear to be either empty and collapsed, or contain less blood than normal. Some of the vessels show haemorrhage into the sheath. (Fig. 3.)

Corpus Callosum.—The small vessels are congested and dilated, some have ruptured into the sheath, other small vessels have ruptured into the tissue. There are no typical punctate haemorrhages such as are seen in gas

* The expenses connected with this investigation were defrayed out of a Government grant of the Board of Control.

poisoning, which are due to hyaline thrombosis of terminal arterioles.

Pons.—There is a marked congestion of veins and some of the smaller veins have ruptured, giving rise to haemorrhage into the sheath; blood corpuscles are also seen extravasated in the adjacent nervous tissue. There are small haemorrhages in the white matter (Fig. 3). There is dilatation of the perivascular sheaths and perineuronal spaces together with collapsed and empty vessels or partially empty vessels. The haemorrhages, here as elsewhere, appear to be of recent occurrence. Nearly all the cells show some degree of early chromatolytic change.

Medulla.—Sections only of the medulla at the point of the calamus scriptorius were made, as the upper part of the medulla was rather damaged. In the anterior median fissure a vessel had ruptured, and there were free corpuscles in the leptomeninges. All the veins on the surface of the medulla were congested. In serial sections the ruptured vessel entering the anterior median fissure and penetrating the median raphe could be followed, and here it was seen to have ruptured into the perivascular space (Fig. 4), and blood corpuscles are seen extravasated into the adjacent tissue. The perivascular and perineuronal spaces are seen dilated both in the medulla and pons (Fig. 7). The cells of the medulla show early chromatolytic changes as a rule. The cells of the vago-accessorius nucleus (Fig. 5) show much more chromatolysis than the adjacent cells of the hypoglossal nucleus (Fig. 6). These nuclei are distant about 2 mm. from the ruptured vessel in the median raphe.

Cerebellum.—Sections stained with thionin and safranin show very unequal staining of the Purkinje cells with the basic dye (Fig. 10). This condition is very similar to that described by Crile in the case of "a soldier who had suffered from hunger, thirst, and loss of sleep; had made the extraordinary forced march of 180 miles from Mons to the Marne; in the midst of that great battle was wounded by a shell; lay for hours waiting for help, and died from exhaustion soon after reaching the ambulance."

Summary of Histological Changes.

There is a generalized early chromatolytic change in the cells of the central nervous system. This change varies in intensity. The cells most affected are the small cells in which the basophil substance has partly or almost disappeared. In the larger cells the Nissl granules are smaller and not packed so closely together as normal. The small cells of the medulla and pons are slightly swollen, and the nucleus is large and clear. This change is present in some of the large cells, but it is less evident. This change indicates a relative degree of exhaustion of the kinetoplasm, assuming that the amount of the basophil substance is an index of biochemical neuropotential. The Nissl granules are not present in the neurone during life, but they disappear altogether in a cell that (prior to death of the whole body) has been so injured as to decay and die. Granted this premiss, then, it may be assumed that the cells of this man are in a state of commencing nervous exhaustion, some nuclei of cells show the changes more markedly than others—for example, the cells of the vago-accessorius nucleus.

The vessels of the pia arachnoid membranes of the brain are congested, and there are scattered subpial haemorrhages of microscopic size almost everywhere.

In the white matter of the corpus callosum, the internal capsule, the pons, and medulla there are seen congested veins and haemorrhage into the sheaths of these vessels, with occasionally extravasation of blood corpuscles into the adjacent tissues.

CASE II.

Clinical Notes.

Captain Duffield reported that information obtained from the medical officer attached to the unit in which the man, a gunner in the Royal Garrison Artillery, was serving, was to the effect that he was sitting in a corrugated iron hut, fifty yards from some boxes of cordite cartridges, when a shell landed and exploded them. The man became unconscious at once; his breathing was stertorous; his body showed no signs of wounds.

On the same day he was removed to a dressing station and thence to a casualty clearing station; in the evening of that day he died. The medical officer there stated that the patient was absolutely unconscious, and could not be roused. His breathing was stertorous and slow; the pupils were equal and reacted to light; knee-jerks were difficult to obtain. He died shortly afterwards, and at the *post-mortem* examination the brain was removed, placed in spirit, and dispatched.

MACROSCOPICAL APPEARANCE OF BRAIN.

On the upper surface of the cerebellum, and upon the temporo-sphenoidal and left orbital lobes there was superficial haemorrhage. On cutting up the pons, oval patches of blood-stained tissue were seen as large as one-sixth by one-quarter inch; whether this is simple staining of haemorrhage cannot be determined until a microscopical examination has been made. Portions of the mesencephalon and pons were taken for microscopical examination; the medulla oblongata was not sent.

MICROSCOPICAL EXAMINATION.

Post-parietal.—Meninges: Marked congestion of all vessels of the surface of the brain with extravasation of blood into the soft membranes. In the grey matter of the cortex the perivascular spaces are dilated throughout, and the vessels, capillaries, veins, and arteries are for the most part empty. In the white matter no punctate haemorrhages are seen; there is marked dilatation of the perivascular spaces; the capillaries, veins, and arteries are empty. In the cortex there is dilatation of the perineuronal spaces, which in many instances may be seen communicating with the perivascular spaces (see Fig. 8).

Ascending Frontal.—Stained with thionin. The large pyramidal cells show pretty marked chromatolysis without swelling of cell; some of the Betz cells show commencing breaking up of the tigroid bodies; smaller pyramidal cells show undoubted swelling of nucleus and loss of pyramidal shape (very similar to that observed in experimental anaemia in animals) with varying degrees of chromatolysis. As a rule, the smaller the cell the more marked is the change (Fig. 9).

Orbital Lobe.—On the under surface there is extensive extravasation of blood into the substance of the brain and on the surface, and there is very marked dilatation of the perivascular spaces everywhere. The cortex is in a measure destroyed in one place; very marked dilatation of perineuronal as well as perivascular spaces, which intercommunicate.

Corpus Callosum.—There is much congestion of vessels, and many have ruptured into the sheath, forming long, irregular branching, haemorrhagic extravasations, but no sign of punctiform haemorrhage. Betz cells seem rather shrunken than swollen in the *ascending frontal*.

Temporal Lobe.—Shows remarkable dilatation of the perivascular spaces, and there is a big globular haemorrhage, and much scattered haemorrhage into the substance of the brain.

OPINIONS OF FRENCH AND GERMAN AUTHORS REGARDING "SHELL SHOCK" BY WINDAGE.

Many discussions have taken place by French and German neurologists regarding the question of organic changes occurring in the central nervous system as a result of *vent du projectile*, or windage. According to Léri, a true commotion appears only to be produced at a proximal distance of some ten metres from great projectiles. The finding of groups of men dead in the last attitude of life, in closed spaces such as the German "pill boxes" and concrete dug-outs, and the proven fact that enormous forces of compression and decompression are generated by the detonation of high explosives in great shells, aerial torpedoes, and mines, has lent support to the view that mere proximity to the explosion is sufficient to cause organic changes in the brain and spinal cord by the compression and decompression of gases the result of the detonation of the explosive and of the atmospheric air; altogether apart from actual concussion caused by violent contact with solid materials, such as sandbags or the earth forming the walls of a dug-out, which may at the same time cause burial or partial burial, unattended by visible evidence of injury of the body sufficient to account for symptoms of cerebral or spinal concussion. The patient is rendered unconscious and his mind is a blank concerning what happened, in a true case of commotio cerebri; consequently he is unable to say whether he had or had not been concussed by the sand or earth. In the two cases under consideration there was no history of burial.

Undoubtedly the vast majority of non-fatal cases of shell shock are more emotional in origin than commotional, and occur especially in subjects of an inborn neurotic or neuropathic temperament; but the two conditions may be associated. Both Léri and Meige emphasize

the fact that commotional symptoms are not influenced by psychotherapy. They also point to the fact that in cases where organic changes have occurred the cerebro-spinal fluid withdrawn by lumbar puncture exhibits macroscopic or microscopic evidence of blood, indicating that haemorrhage had occurred.

In Case I Captain Stokes noted at the *post-mortem* examination that the fluid was blood-stained, and the microscopic findings of ruptured vessels explain this.

Léri states that the subjects of commotion are generally depressed, asthenic, aboulie, and often more or less confused mentally; they present almost constantly, even in light cases, pronounced disturbances of voltaic vertigo. They often suffer with bleeding from the ear, or nasal or vesical haemorrhage. Roussy and l'Hermitte admit that in rare cases "*vent du projectile*" may cause organic changes.

Robert Bing gives a review of the German opinions upon nervous accidents determined by the near explosion of a projectile. He points out that Vogt and Gaupp, who have occupied themselves with "*Granat Kontusion*" (bomb contusion), are far from accepting the exclusive psychogenic rôle in the development of this syndrome. Gaupp insists particularly upon the relations which exist between the initial symptoms presented by these patients and the rapid succession of atmospheric compression and decompression which takes place at the moment of the bursting of the projectile. The existence of labyrinthine lesions, almost regularly in this class of case, is in support of this opinion (Schultze and Meyer).

In Von Sarbo's numerous publications upon the subject there is a tendency to view these cases from a uniform point of view. For him the general mass of observations do not permit the diagnosis of organic changes in the usual sense of the word, nor that of psychoneurosis. He believes micro-structural alterations occur, but which are not equivalent to the molecular changes of Charcot. He includes in the micro-structural changes meningeal oedema, microscopic haemorrhages, transitory paralysis of vessel walls, and contusion of nuclei and centres. In the initial period these lesions may give rise to some discrete symptoms of organic disease; later they are manifested by functional physical and psychological symptoms. Bing remarks that the pseudo-neurasthenia of arterio-sclerosis supports this view. It is interesting to note that the haemorrhages into the perivascular sheaths of vessels observed in Case I resemble in some respects those seen in arterio-sclerosis.

Oppenheim's view of traumatic neuroses had few supporters at the congress at Munich. Clarence Farrar sums up thus the work of a German psychiatrist:

"Aschaffenburg examined soldiers in Flanders who had been exposed to shell fire in the trenches but had escaped unscathed and were apparently well. The examinations took place in most cases within twenty-four hours after leaving the trenches. Of 74 men so examined, 67 showed unmistakable signs of localized organic lesions of the nervous system, although not as a rule of a serious nature. A second examination a week later showed that some, but not all, of these phenomena had disappeared. Here were cases, therefore, in which an organic basis was present but no traumatic neuroses had developed. Aschaffenburg gives the result of his experience in these words:

"In assuming organic changes as one of the consequences of shell explosion I do not thereby agree with Oppenheim that the nervous symptoms are to be attributed to these changes. On

the contrary it is to be noted that the most exaggerated hysterical cases which develop after exposure to shell firing are the ones which exhibit organic symptoms least of all."

Hypotheses regarding the Lesions of "Commotion."

Two hypotheses have been put forward to explain organic lesions by "commotion":

1. Compression of the gas and atmosphere, so that the cranium and spine is struck, as it were, by a solid body and the vibration is transmitted through the bony structures to the cerebro-spinal fluid and thence to the brain and spinal cord, causing a molecular disturbance of the delicate colloidal structures of the neurones, particularly those of the nuclei in the floor of the fourth ventricle, where the fluid is most abundant, and where it acts as a water cushion upon which the vital cardio-respiratory centres rest.

2. Compression is followed by a corresponding decompression, causing the liberation of bubbles of gas in the blood and tissues leading to embolism.

Probably both the forces of compression and decompression act in producing vascular disturbances in the central nervous system, causing arterio-capillary anaemia and venous congestion.

COMMENTARY.

In Case I, of which I have described the histological changes, it may be observed that there was a condition of mania during life; this maniacal excitement may be correlated with the marked venous congestion of the cortex, the microscopic subpial haemorrhages, and a certain degree of scattered arterio-capillary collapse and emptiness. This, however, could not be held responsible for the suddenly fatal termination; the haemorrhage into the sheath of a fair-sized vessel (see Fig. 4) in the median raphe of the medulla and the generalized congestive venous stasis, with a condition of exhaustion of the cells of the vago-accessorius nucleus (as shown by the almost complete disappearance of the Nissl granules (see Fig. 5) as compared with the cells of the adjacent hypoglossal nucleus), coupled with the

condition of the heart found *post mortem*, may explain the sudden death.

The cerebral anaemia, as shown by collapsed and empty arterioles and capillaries with dilated perivascular and perineuronal spaces (see Figs. 7 and 8), is similar to the appearances in sections of brains of animals that have been killed within a few days after ligation of both carotid and vertebral arteries. The veins are congested similarly, but the capillary anaemia and chromatolytic changes would possibly explain many of the symptoms of sufferers with true shell shock—namely, headache, giddiness, amnesia (anterograde as well as retrograde), dizzy feelings, lack of power of attention, and fatigue—stupor, inertia, mental confusion, terrifying dreams—symptoms which are generally met with in recent cases.

There is, in both Cases I and II, a general, though as a rule not marked, chromatolytic change indicative of a lack of kinetoplasm in the neurones of variable degree. This may hypothetically, but with reason, be regarded as an expression of a fall in the general store of neuro-potential of the central nervous system. The cells of Purkinje of the cerebellum show especially a complete or partial loss of the basophil substance.

The vascular changes are microscopic and widespread; there are no punctate haemorrhages of the white matter, such as I have described in gas poisoning, and which are due to a hyaline thrombosis of terminal arterioles. The

DESCRIPTION OF SPECIAL PLATE.

DR. F. W. MOTT.

FIG. 1.—Betz cells of leg area. There is commencing chromatolysis of varying degree. The Nissl granules are not so closely packed together as in normal cells. The nucleus is larger and clearer than normal. Magnification 300.

FIG. 2.—A small vessel cut longitudinally in the internal capsule. The vessel is filled with blood corpuscles; the perivascular sheath is seen dilated and filled with red blood corpuscles. Magnification 193.

FIG. 3.—Haemorrhages into the white matter of the pons. Magnification 82.

FIG. 4.—Haemorrhage into the sheath of a vessel in the median raphe of the medulla. Magnification 136.

FIG. 5.—Cells of the vago-accessorius nucleus at the level of the calamus scriptorius. Observe the marked chromatolysis and eccentric position of the nucleus. Compare the same with Fig. 6. Magnification 343.

FIG. 6.—Cells of the adjacent hypoglossal nucleus, showing early slight chromatolysis. Magnification 343.

FIG. 7.—An arteriole breaking up into capillaries with dilated perivascular space. This space is in communication with the perineuronal space around the nerve cells. Magnification 257.

FIG. 8.—Section of cortex, Case II. Dilated perivascular space around collapsed arterioles and capillaries. Dilated perineuronal spaces. Magnification 322.

haemorrhages are into the dilated perivascular sheaths (see Figs. 2 and 3). In the corpus callosum the networks of capillaries and small vessels show fractures and escape of corpuscles into the tissues. The microscopic changes in the brain confirm in every way the opinion expressed by Captain Stokes when he made the *post-mortem* examination that he was dealing with a case of shell shock.

In Case II the extensive haemorrhage on to the under surface of the orbital lobe without visible external injury is of interest. The force of the explosion must have been enormous. What happened to the man when it occurred we do not know. The cortical, arterial and capillary vessels were empty, the perivascular sheaths were in many places dilated and filled presumably with cerebro-spinal fluid (see Fig. 9). The cortical neurones are swollen up, the nuclei are large and clear; the basophil substance is diminished in amount, a condition very like that observed in the cells of the cortex of an animal in which experimental cerebral anaemia had been effected. Owing to the brief clinical and *post-mortem* notes this case is of much less interest than Case I.

I am unable to find in the literature at my disposal any description of the microscopic changes in the brain of soldiers dying from commotio cerebri without visible external injury.

Mairet and Durante have exposed animals to the compressive and de-compressive forces generated by detonation of high explosives. They found scattered through the brain and spinal cord minute haemorrhages caused by the rupture of small vessels. The blood is found in the lymphatic sheaths. The vessels most commonly ruptured are those which have the least support by solid tissue; in fact the description of their findings closely corresponds with that in the above cases.

PRELIMINARY REPORT ON THE PATHOLOGICAL FINDINGS IN NERVES FOLLOWING WAR INJURIES.

[WITH SPECIAL PLATE.]

BY

CAPTAIN SYDNEY M. CONE, M.O.R.C., U.S.A.

From the Alder Hey Military Orthopaedic Hospital, and the Thompson-Yates Laboratory, University of Liverpool.)

THE incentive to the work I am doing on nerve pathology comes from Colonel Sir Robert Jones, who has placed the extensive material from the Alder Hey Military Orthopaedic Hospital in my hands. The University of Liverpool and Professor Ernest Glynn, Captain R.A.M.C.(T.), have given me every facility and aid in prosecuting my studies, and I am greatly indebted to them.

This is only a preliminary report of work covering three months' service at the hospital, and is produced principally because I feel I can give some material assistance to other workers along these lines by presenting the staining reagent which, after three months' work, I finally found to be most satisfactory. Without a good stain for axis cylinder and medullary sheath one cannot do nerve

work in the laboratory. Many of the stains require unusual experience before they can be used satisfactorily. I tried Stroebe's stain without success. In order to make use of it Kennedy had to use the aniline blue for twenty-four hours. Bielschowsky's axis cylinder stain required several days and did no contrast staining; maybe it had to be done over again. It was most useful early in my work, as was also a modification of Howell and Huber's picric acid haematoxylin method. The stain I have to give workers in nerve pathology is one based on a technique I used in Heidelberg when working on nerve degeneration in Kühne's laboratory in 1895. It brings out the axis cylinders in distinct relief as pink covered by a thin line of purple-black—the medullary sheath "neuro-keratin framework" faintly tinged purple-black—the red blood cells brown, the nuclei pink, muscle deep red, connective tissue unstained, or a very faint pink.

Where the axis cylinders are just formed they always have a purple appearance. Not infrequently fine lines 1 to 2 μ in width are seen among the wider fibrils, the finer ones appearing deeper stained than the wider ones because of the pink centres of the fuller-grown fibres. These forming axis cylinders may be easily picked out in adhesions as purple lines against a very faint pink connective tissue background. There are modifications in the structure of the axis cylinders and nerve fibres in denser connective tissue, but the staining reaction remains unmodified. In one specimen of unusually dense connective tissue formation in the proximal end of an excised nerve the axis cylinders were very irregular, varicose, and of a rough outline by turns,

yet the purple border about the pink central tendril was present. Some of the larger fibres showed a vacuolated appearance, in which case the vacuoles were outlined by a fine blue-black stain. Tinel refers to this in "stump neuromas" as a *gonflement* of myelin.

As a rule, the fully developed nerve shows the axis cylinder "capped" at regular intervals by a pyramidal purple material deeply stained against the axis cylinder, and fading away gradually. Tinel speaks of this appearance as "bearded" or "prickled with thorns," and refers it to deeper silver impregnation at these points—the incisures of Lantermann.

Technique.

The specimens are hardened in 10 per cent. (or, according to some laboratories' computation, 4 per cent.) formalin and then carried through the alcohols to ether and absolute alcohol and celloidin. Although thin sections are preferable, good results are obtained with 20 μ thick sections.

The section is washed in water, placed in carbol-fuchsin fifteen minutes, momentarily in water, 1 per cent. osmic acid five minutes, water two minutes, watery safranin 50 per cent. one minute, acid alcohol 1 per cent. two minutes, 95 per cent. alcohol five minutes. Absolute alcohol and oil of cloves are now used alternately until the section appears deep pink but translucent; it is then placed in xylol for two minutes and mounted in Canada balsam.

Advantages.

The great value of seeing the nerve fibres distinctly outlined against connective tissue, cell proliferation, and blood vessels will be appreciated at once by those who examine tissue from the great number of excised "nerve callus" masses of war surgery.

In our experience we have had so far more than one hundred cases to examine. We have sectioned the excised nerves at proximal end, distal end, middle, and adhesions, including muscle and fat. We have had old operations to go over in some of which Cargile membrane, fascia wrapping, or veins had been used. In one case a rabbit's nerve had been used as a graft. This material was stained in about twenty-five different ways before the above-described method was adopted. The only method that approached satisfaction was that of Bielschowsky.

Method of Examination.

Some of the notable observations in my work have been the irregularity of growth of new fasciculi of nerves in the proximal end of the nerve about the old parallel running fibres, as far as the bulbous enlargement at the wound. There is invariable infiltration of the nerves with blood, new formed capillaries within and about the nerve, and little evidence of round-cell infiltration (most of our nerves were injured over eight months earlier). Connective tissue formation of varying density both within and about the fibres is the rule. The peripheral end always shows a great cellular proliferation with elongated spindle-shaped nuclei, usually arranged in little clumps and interlacing, running in various directions, resembling the arrangement of nerve fibrils in the bulbous enlargements in the stumps we have examined. In some of these we found axis cylinders well stained; in others repeated staining failed to show fully formed nerves.

The method of operating on these old torn nerves has been pretty definitely outlined, and is done in the same way at most of the base hospitals where the paralysed are treated some months after the original wound has healed.

The nerve is exposed with careful regard to all anatomical relations—adhesions relieved by sharp dissection in a line parallel to the fibres. Blunt dissectors are used when adhesions are pretty well localized to the immediate seat of nerve tear or cut, where a bulbous enlargement is usually seen. The work on the denser adhesions about this point is facilitated by raising on the dissecting elevators the freed portion of the nerve at the proximal and distal side of the bulbous mass included in adhesions. When the nerve in its continuity can be raised free of adhesions so much of it is excised as will leave greyish-pink moderately soft nerve ends. Here it is cut through and sutured with chromicized catgut. These sutures, about four in number, pass through the outer sheath. It may be necessary to stretch the ends, transplant the nerve, and use an approximation suture which passes through the entire thickness of the nerve. The limb is placed in a position giving greatest relaxation to the nerve and muscles. Occasionally one meets with a case where relief of adhesions alone is deemed sufficient. There are cases where longitudinal incisions through the swollen injured part have been made. Cargile membrane, fascia, or muscle covering are used to protect the area of suture from future adhesions.

Observations and Results.

The material removed at these operations has been placed at my disposal since June 14th, 1917. I have used formalin as a rule as hardening agent, but picric and osmic acid have also been employed. Material from both ends, mid-portion (this is usually the bulbous part), and adhesions were examined in various ways and by different stains. Glycerin mounts were made of teased specimens, in which case the picric acid hardening and carbol-fuchsin-haematoxylin staining were most satisfactory. Howell and Huber recommended the picric acid-haematoxylin (Boehmer's) method. In fact, I find this haematoxylin most useful in the study of the cell proliferation. We invariably found good old nerve fibres in the proximal end, but very often these were intertwined by a mass of new young tendrils in small fasciculi and many young capillary blood vessels coursing in various directions about them.

In some cases no fibres at all were seen at the bulbous enlargement, but this was very rarely the case. As a rule old connective tissue, sometimes sclerotic in character, was found here, but even in this well-stained axis cylinders, single and in fasciculi, were detected (Tinel).

Wherever young fibrils were found there was a great cell proliferation. The distal end was always quite cellular, the nuclei of the cells, as a rule, were elongated and staff-shaped. In fact, the cellular areas here and in the bulbous portions frequently gave the appearance of a leiomyoma such as we so frequently find in the body of the uterus. Tinel calls such cellular areas gliomas. In a number of our cases we found quite a great many fasciculi of well-formed young nerves with axis cylinders in the distal end.

The adhesions invariably contained cellular young nerves, some with a faint line of myelin covering the axis cylinder,

others grown to adult age and well protected by medullary sheath and sheath of Schwann.

My examinations of nerve bulbs from stumps corroborate Thomson and Kennedy's findings. I find more good fully formed nerves than connective tissue and an unusual proliferation of the cells of the sheath of Schwann, called by Tinel, von Bungner, and others, neuroblasts.

For those who wish to read the best that has been written on the subject of regeneration and degeneration of peripheral nerves, I would refer to the bibliography in articles written by Howell and Huber, von Bungner, Alexis Thomson, Kennedy, Stroebe, and Luciani's *Human Physiology*, vol. iii, translated by Welby.

The very recent book by J. Tinel, *Les Blessures des Nerfs*, published by Masson et Cie., 1916, gives a brief but comprehensive surgical pathology of injured nerves. My findings are in accord with his regarding the contents of the bulbous injured parts. He names the swelling a neuroma when it is made up of regenerated nerve fibres, such being usually found in the proximal (central) end. It is a pseudo-neuroma when it is made up of a thickening of the enveloping tissue by haemorrhage, fibrous tissue and proliferation of the neurological elements. This is usually found on the swelling of the peripheral end. He names these proliferating cells from the sheath of Schwann neuroblasts, with von Bungner, S. Meyer, and Kennedy.

Gluck thinks that there are real large protoplasmic ganglion cells among the sheath of Schwann cells, which are responsible for the formation of the new fibril.

I find great numbers of these neuroblasts in adhesions and at both ends, but particularly in the distal end—so numerous, in fact, that I can well understand why Tinel should use the term glioma for such cellular areas of the "pseudo-neuroma."

Tinel definitely states that the regenerating nerve always proceeds from the central end, using the old sheaths for a pathway and attracted by the "neurotropismus" of the proliferating cells of the sheath of Schwann. This neurotropismus or chemiotropic influence referred to by Langley and Anderson, and admirably worked out experimentally by Forssman, is not an uncommon explanation of the influence and only part played by the distal end.

Some say that the distal end produces good nerves autogenetically, others believe that they grow up to a certain stage and only form well-developed axis cylinders when brought in communication in some way with nerve centres; and here we have another use of the cells as expressed by Tinel, Mott, Halliburton, and Edmunds consider the activity of these neurilemma cells to be nutritional in nerve repair.

I will go quite fully into the various views about new nerve growth, as borne out by my pathological material, in a later, fuller communication.

ADDENDUM.

I wish to add to the above a description of some interesting microscopic findings which are of assistance in interpreting conditions as seen in the stumps of nerves, adhesions, and the nerve callus. In staining the specimens, the safranin used as described above is omitted; it is not an essential part of the staining method.

Ranvier described what he called "renflements biconiques"; Tinel writes of nerves "barbelé" or "hérissée d'épines"; von Bungner, Stroebe, and others have disputed about the incisures of Lantermann. Stroebe even denied that neurokeratin is in the medullary sheath. Arndt, with Kuehne, Kuhn, Joseph, and Tuckett, arrive closer to our pictures when they speak of a neurokeratin sheath and myelin framework, "a sheath-like element stained with acid fuchsin" which surrounds the axis cylinder. Ranvier was not very far away when he wrote of a colloid material about the axis cylinder at the constricting node. However they look upon the axis cylinder in its relationships to the medullary sheath, there is no question but that most histologists have kept them distinctly separate. The above-named physiologists, through the neurokeratin material, worked to varying degrees by the different men into the framework of the medullary sheath and immediate surroundings of the axis cylinder, blended them into a more harmonious connexion.

It is to demonstrate this connexion that my stain is especially adapted. I have referred above to the fine single and double lines of purple (more accurately called

mauve) about even the smallest axis cylinders. This is due to the neurokeratin contents of the youngest fibre.

Two histological points are to be noted even in the youngest fibrils of adults or embryo; one is the cones, barbs, *renflements biconiques*, or whatever they be called, and the other is the so-called vacuoles, *gonflements* of myelin moniliform appearance of the fibrils, due to the neurokeratin framework. They show so clearly with my neurokeratin stain that the photographs I am preparing will speak better than words.

There is one fact that should be noted, however—that is, that stretching or compressing a nerve draws out this neurokeratin support into cone-shaped form, leaving the point finely drawn out along the axis cylinder, which it ensheaths, and the base toward the sheath of Schwann, each cone being from 10 to 40 μ long, depending on the amount of stretch. The base appears more deeply stained—not so; it is merely that, being at the wider attachment, there is a greater amount of it stained at the point viewed; this masses the pigment.

There are a number of interesting points that one can explain, and work is now in progress to put a correct interpretation on many long and acrimoniously discussed questions.

THREE CASES OF MELAENA NEONATORUM SUCCESSFULLY TREATED BY THE INJECTION OF WHOLE BLOOD OR BLOOD SERUM.

By ROBERT HUTCHISON, M.D., F.R.C.P.

THERE is, of course, nothing new in the treatment of the haemorrhagic disease of the newly born by the injection of human blood or blood serum. It was introduced, I believe, by J. E. Welch in the year 1910, and many successful cases have been recorded since, especially in America. In this country, however, it does not appear to be very generally known yet, so it seems worth while to put on record the three cases described below, which occurred consecutively.

CASE I.

A female child, aged 2 days. The day after birth began to pass blood from the bowel; no haematemesis nor bleeding elsewhere.

On admission the child was blanched and profuse melaena was present. The same evening 5 c.cm. of human serum obtained from the blood of a patient with erythraemia was injected *sub cutem*. Next day there was a small attack of epistaxis but no further bleeding from the bowel, and the child was discharged a week later apparently well.

CASE II.

A male child, aged 4 days. Two days after birth several haemorrhages from the bowel took place, the last just before admission. The child was well nourished but pale and slightly icteric. Two hours after admission 5 c.cm. of serum, obtained from the same patient with erythraemia as in the first case, was injected under the skin of the back. Six hours later the

child looked much better and only one further slight attack of bleeding had occurred. Next day the stools were normal and three days later the child was discharged.

CASE III.

A male child, aged 30 hours; a healthy-looking well-developed child of normal colour. Blood was noticed in the first action of the bowels after birth and four tarry stools had been passed since. There had been no haematemesis. The napkins showed typical melaena of considerable amount. On the afternoon of admission 8 c.cm. of whole blood furnished by the ward sister were injected into the subscapular region. In the next twenty-four hours there were four more small tarry stools, after which the haemorrhage ceased, and the child was sent home well three days later.

How the serum acts it is impossible to say with certainty, but it seems probable that it supplies some constituent which is lacking in the infant's blood and which is essential for clotting. I used human blood or blood serum in all the cases described, but normal horse serum or antidiphtheritic serum would probably do as well.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE TECHNIQUE OF NERVE SUTURE.

THE device here described may be strongly recommended for revivifying the neuromatous ends of divided nerves. It is simple, cheap, and effective. The essential point is the use of a safety razor blade, held in a pair of Halsted artery forceps, for division of the nerve. The blade—as supplied for a Gillette or other brand of safety razor—must be gripped quite firmly by the forceps, when it will be found more satisfactory than the sharpest scalpel. This device is used extensively at the orthopaedic centre, Blackrock, by Colonel Wheeler, who now prefers it to any other type of instrument for this purpose. The technique is as follows: The neuromatous end to be freshened is grasped by its fibrous sheath by two artery forceps clipped directly opposite one another, and the end of the nerve is divided by the razor blade until the brush-like ends of the healthy funiculi appear. A catgut suture is then inserted, and the two ends are approximated. The second suture is then inserted, and the first is cut. In like manner the other sutures are inserted, and the nerve ends are brought together accurately, and, if possible, the funiculi themselves are placed in apposition. The advantages of the razor blade are: (1) A sharp edge can always be obtained; (2) the nerve fibres can be cut horizontally with the least bruising of the structures. This device, therefore, seems worthy of bringing to the notice of neurological surgeons in other stations. Incidentally, I might add that the employment of tissue, such as Cargile membrane, etc., has been given up, for, as far as can be judged, it increases rather than diminishes the subsequent fibrosis near the sutured nerve.

J. McCULLAGH, M.D.,

Temporary Captain R.A.M.C.; Assistant Surgeon, Blackrock Centre.

PARAFFIN AND BISMUTH FOR GASTRIC ULCER.

I HAVE found a mixture of bismuth subnitrate and liquid paraffin of use in the treatment of gastric ulcer. The bismuth salt may be rubbed up with ordinary liquid paraffin to form a smooth cream. It is taken thus without producing much nausea, and with increasing tolerance.

The liquid paraffin is a good vehicle for bismuth, undoing its constipating effect. The patient is more comfortable, and less flatulent than when taking bismuth alone.

The action of the combination may be supposed to resemble that of bipp in the treatment of external wounds. The special electrical effects of paraffin on wounds, mentioned in your issue of October 20th, are unfamiliar ground to me. Apart from that, the combination deserves a trial.

Holmes Chapel, Cheshire.

LIONEL JAS. PICTON.

AN official statement has been published denouncing the bad treatment of Italian prisoners by the Austrians. Their food is altogether insufficient for the maintenance of health. The conditions in concentration camps with regard to the accumulation of prisoners and the exhausting labour demanded are extremely bad, and the amount of sickness and the mortality extremely high.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

THE autumn meeting of the Dorset and West Hants Branch was held at Bournemouth on October 17th, when the President, Dr. T. HOWARD, was in the chair.

Neurasthenia and Allied Conditions.

Dr. F. C. FORSTER, in opening a discussion on neurasthenia psychasthenia, shell shock, and allied conditions, said that neurasthenia is a complex of symptoms induced by nerve exhaustion and associated with, if not actually causing, a change in nutrition. It is nearly always due to a combination of mental overwork and worry. It is the mental shock that accompanies a physical injury which gives rise to traumatic neurasthenia or shell shock. The most prominent symptoms common to nearly all cases are: depression, lassitude often combined with restlessness, insomnia, loss of power of concentration, failure of memory, headache, abnormal sensations in different organs, dragging pains, palpitation, and loss of appetite and vitality. The importance of excluding organic disease as a causative factor was pointed out and illustrated by the following case: A gentleman, aged 45, had broken down apparently under the strain of financial and air-raid worries, and had been advised a rest cure. He had all the usual symptoms of neurasthenia, but, in addition, an area of tenderness and rigidity was found in the epigastric and right hypochondriac regions. A skiagram taken after a bismuth meal showed the necessity for exploration, and the case proved to be one of malignant disease of the duodenum. The keynote of the management of these cases is to induce "self-forgetfulness," to do away with the inertia, to improve the *moral* by encouraging independence, and to adjust the patient's life. In acute cases a suitable nursing home is imperative, and the chief essential is to procure sleep. For this gentle massage (effleurage or some of the softer stroking movements) is helpful and a pack and warm bath useful adjuncts. If drugs are necessary, chloralamide is better than paraldehyde or bromides. For the general excitation, monobromated camphor with conium is useful. The acute stage over, a short Weir Mitchell course (two to three weeks), followed by occupation with some interesting hobby, is better than a prolonged rest cure. Interest in life is needed, and at this stage tonics, physical, psychical, and mental, may be of the greatest use. Drugs are better avoided. Suggestion in its various forms is of undoubted value. Static electricity for pure neuroses and high frequency for cases of high tension and deficient metabolism are helpful. Finally, change of air and climate and, more important, change of mental or psychical environment are essential. One of the leading points in the treatment was illustrated by the following case: An officer in the Royal Flying Corps met with shell shock. After some weeks' treatment abroad he was transferred to an officers' hospital in this country. Two months later he was sent to a hospital for nerve disorders, then a month later to a convalescent hospital, and finally, as he was still going steadily downhill, to a nursing home for six weeks' rest cure. Gaining no benefit, he was eventually invalided out of the army. When seen his condition was pitiable. He was wasted, wracked with insomnia alternating with terrifying dreams, hopeless as to any improvement, a prey to vague terrors, afraid to be left alone, and devoid of any confidence in himself or others. Evidently in this case the first thing to do was to restore self-confidence and prove to him that he was capable of some sort of work and so make him increasingly dependent on his own efforts. He was found a suitable occupation and made to depend for the necessities of life on his own work. Under this régime he rapidly improved and was soon able to rejoin the army. The case emphasizes the point that a much earlier return to work will be far more beneficial to many neurasthenics than the prolonged stereotyped rest cures in a nursing home, which engender in the patients a spirit of dependence on others rather than on themselves.

In the discussion which followed, Dr. MACDONALD laid stress on the importance of some suitable occupation instead of a prolonged rest in a nursing home, and spoke

of the danger of sending men back to the front too soon after a nervous breakdown. Dr. JOHNSON SMYTH drew attention to the importance of distinguishing the various forms of the disease. He distinguished (1) the pure neurotic, who may have a raised blood pressure; (2) the neurotic with a neurasthenia engrafted—here we often find a low blood pressure and a subnormal temperature; (3) the neurasthenia following severe illnesses, as fevers, etc.; this is as a rule easily curable by rest, diet, massage, and mental diversion. Dr. FOWLER, speaking of electrical treatment, said he used either static or high frequency. Dr. SIMMONS drew attention to the frequency of neurasthenia after operations and accidents. Dr. E. BOND spoke of the beneficial effect of "war work" on female neurasthenics and of the difficulty there would be after the war in finding suitable occupation for this class of patient. Dr. HUMPHREY DAVY drew attention to the great difficulty of treating neurasthenia in old patients. Dr. LE FLEMING thought it was all-important to increase the weight of these patients. He drew attention to cases in which a neurasthenia was grafted on some gross nerve injury or lesion and the importance of disentangling the symptoms due to the organic and functional trouble in these cases. He emphasized the value of "suggestion" treatment and quoted a very successful case treated in this way.

Certification of Patients for Asylum Treatment.

Dr. HUMPHREY DAVY then read a paper on this subject, drawing special attention to the following points: In many cases of suicide in which the verdict is temporary insanity, pre-existing aberration of mind exists, suicide being the last act of the mental breakdown. Delay in certifying is due to difference of opinion as to the stage at which the patient should be certified. Some doctors look for the existence of delusions or acts of violence as absolutely necessary before certifying. It is important to bear in mind the two great divisions of insanity: (a) Moral; (b) intellectual. Moral insanity may exist with a fair amount of intelligence and freedom from delusions. Delay in certifying may result in a curable case becoming incurable. The following conditions should be noted for guidance in a suspected case: The patient's personal symptoms and family history; record of any special stress; history of alcohol, syphilis, diabetes, malaria, epilepsy, gastro-intestinal disorders, etc. The periods of puberty, climacteric, and senility should be specially watched, and such symptoms inquired into as sleeplessness, frontal headache, inability for mental work, egotism, fear of persecution, loss of weight, failure of memory, or change in the patient's general aspect. Lastly, neurologists would do well to include in their curriculum one year of resident asylum practice.

Reports of Societies.

ANAESTHETICS IN MILITARY HOSPITALS.

At a meeting of the Section of Anaesthetics of the Royal Society of Medicine on November 2nd, the President, Mr. GEORGE ROWELL, being in the chair, Lieut.-Colonel J. F. W. SILK, R.A.M.C., opened a discussion on anaesthetics in home military hospitals.

SELECTION OF ANAESTHETIC AND METHOD.

Chloroform pure and undiluted was, he said, to be avoided when possible. The mortality was high even with skilled anaesthetists. In about 55 per cent. of the deaths reported the anaesthetic given was chloroform. It was of value in many cases, especially when given diluted with ether and by the open method.

For short cases three methods of anaesthesia were suitable: (1) Local anaesthetics, perhaps not used as often as might have been expected before the war; (2) nitrous oxide; (3) ether, which should be given preferably by the open method.

The preliminary injection of morphine and atropine should be almost a matter of routine. Sometimes hyoscine was added to the mixture. If ether was to be administered atropine should always be given, as it dries up the mucous secretion. Instead of the orthodox hour before the operation, he gave the injection half or even a quarter of an hour before, and it should be given in the anaesthetic

room rather than not at all. He advised morphine $\frac{1}{4}$ gr. and atropine $\frac{1}{100}$ gr. For the mask he preferred gauze to lint. When time was no object ether should be used from the beginning, otherwise it was best to begin with a mixture of chloroform and ether. To hasten induction he often began with ethyl chloride dropped on an open mask, or used ether in a Clover inhaler. McCardie's drop bottle had as advantages that the amount could be easily regulated, and the bottle was not easily broken. He now used a nasal tube passed back into the pharynx, which ensured a free airway even if the jaw muscles became stiff, and the tube could not be occluded even if the epiglottis and tongue fell back. Most hospitals were provided with Clover inhalers, and he had suggested McCardie's proportion of one drachm of chloroform to each measure of the inhaler; he preferred the open method. Less chloroform and more ether had been given in home hospitals than in the past year, with increased safety to the patient.

Anaesthetics in Special Cases.

In *shock* he thought too much morphine could not be given, but it should be avoided in septic cases, and in patients with malaria or with heart trouble. In these cases chloroform also should be avoided. As little anaesthetic as possible should be given, and it should be diluted with oxygen which could be bubbled through the ether. Nitrous oxide was valuable, but the apparatus militated against its use and he was not satisfied with the anaesthesia produced. Warm ether was of advantage in these cases. Continuity and regularity were great points in success.

In *intracranial cases* morphine was unnecessary, and here also very little anaesthetic should be given. He preferred chloroform, as it lowered venous congestion.

In *empyema* the mortality was severe. For these cases he preferred intratracheal methods, and thought that the patients should be concentrated in the better equipped hospitals where this apparatus was used. Otherwise he preferred chloroform and oxygen.

In *spinal cases* the patient had to lie on his face, and the chest was consequently compressed so that the anaesthetic had to be pumped into him, and venous congestion was always present. He thought chloroform and oxygen the most desirable anaesthetic.

In *orthopaedic surgery* spinal anaesthesia was not used as much as might have been expected. Nitrous oxide was often used, and acted well when given with ether, but venous congestion should be avoided; warm ether produced this.

In *plastic surgery* of the face and allied conditions the chief difficulties were caused by the blood and mucus which collected in the mouth and pharynx; there was also the difficulty of manipulating the anaesthetic with a fixed or very mobile jaw. In the majority of cases exceptional methods were necessary, and of these he mentioned four: (1) The *intratracheal*, which was not necessary in all or even in the majority. (2) *Intubation* was little known in this country, but had many advantages; it was easy to introduce Kühn's tube, which could be packed with gauze round the pharynx, thus preventing blood from entering. (3) *Rectal oil-ether* method. In this there were two important points: (a) The patient should have morphine and atropine before, and (b) the anaesthetist should himself see that all remnants of oil-ether were washed out of the rectum. (4) *Method of position*. In this the patient sat bolt upright, and anaesthesia was produced by passing oxygen and chloroform or other vapour through a nasal tube. This method had been in use for over a year at one of the principal facial hospitals, and so far no fatality had occurred.

Ether bronchitis used to be put down to exposure, but that explanation would not hold. In some places it appeared endemic, in others epidemic, whilst in others it was absent when it might have been expected to have occurred.

DISCUSSION.

Mr. BELLAMY GARNER said that the nasal air tube afforded an important method of overcoming a difficulty. Apart from the adoption of the mouth prop the only other suggestion was tracheotomy. He thought the mouth prop should always be used.

Dr. J. BLONFIELD said that he had learnt to appreciate the intratracheal method in plastic surgery.

Major H. D. GILLIES said that, by Colonel Silk's advice, he had adopted the sitting position, and also intratracheal methods. In plastic surgery an anaesthetist was needed who could give every known form of anaesthesia. It was often impossible to use the intratracheal method owing to the form of injury. The sitting position had the advantage that the tongue and jaw tended to fall forward. Nitrous oxide and oxygen had given good results. Each case had to be considered from the anaesthetic point of view. The intratracheal was the ideal method if it could be done. Kühn's tube was a good substitute, but the large apparatus in the mouth was a disadvantage. Chloroform and oxygen given through the nasal tube, with the patient in the sitting position, had given good results.

Dr. F. E. SHIRWAY said that he always induced anaesthesia with chloroform and ether on the open mask and then continued with ether. He did not agree with Colonel Silk's opinion that too much morphine could not be given in cases of shock. Morphine was a depressant, reduced temperature, lowered blood pressure, and diminished excitability, thus producing a condition similar to shock. When shock had developed he thought that morphine should not be given in larger doses than one-sixth of a grain, or a quarter of a grain at the outside. In empyema he preferred ether or warm ether. Light anaesthesia was very necessary. In facial cases he preferred intratracheal ether, and in only 6 per cent. was he unable to pass the catheter. The advantage to the patient was the absence of post-operative vomiting. Sickness could not be avoided after chloroform in the sitting position. Oil-ether by the rectum was occasionally a very valuable method, but he doubted if it were free from danger on account of irritation of the lower bowel. Mr. Page had suggested less ether, but Major Gillies found that less than the amount recommended by Gwathmey was not enough.

Captain H. EDMUND G. BOYLE objected to the use of chloroform for the induction; a mixture of ether or gas and ether should always be used. He did not agree that the apparatus militated against the gas and oxygen method. Speaking of plastic surgery, he said that he had anaesthetized twenty-three cases with oil-ether by the rectum and had tried to change the dosage. He now used paraldehyde 1 drachm, olive oil 2 oz., and ether 4 oz. He had had no cases of irritation of the rectum. He thought the mouth prop should always be used, but that there was no need for the nasal tube.

Mr. PERCIVAL P. COLE said that very well-trained anaesthetists were necessary for plastic operations on the face. He thought it was rarely impossible to pass the tube. Kühn's tube was not so good, as the operations usually lasted a long time, and the physical exhaustion produced in the patient by breathing through Kühn's tube was marked. This did not occur with the intratracheal method. Vomiting was rare.

Colonel SILK said, in reply, that the oil-ether method required care. He had never had a case of rectal irritation. In shock he recommended a quarter to half a grain of morphine. He was pleased to find that the meeting was so thoroughly in accord with his condemnation of undiluted chloroform for routine use in military hospitals.

Dr. H. R. PHILLIPS demonstrated an apparatus for administering oxygen with ether and chloroform. The oxygen, contained in two cylinders, was passed through hot water contained in a copper tank, and thence through the chloroform or ether, or through both.

YALE UNIVERSITY has lately received gifts amounting in the aggregate to £72,478. The largest single donation was one of £20,000 from Mrs. E. H. Harriman for the Harriman Fund for Obstetrics in the medical school.

THE mites which infest cheese have been studied by Nellie B. Eales in the zoology department of University College, Reading. There are four species, all of which will attack Cheddar, and three Stilton, but their habits and life-history are very similar. They go through the usual stages of egg larva, nymph, and adult. They can live through the winter in crevices in boards or walls, are not destroyed by ordinary washing, but can be quickly killed by carbon bisulphide. Experiments prove that they may be carried from one cheese to another by flies and moths. The loss caused by them is considerable, being estimated at about 3 per cent. of the total value of the cheeses. Although they chiefly attack the kinds of cheese mentioned, they will attack old samples of other sorts.

Reviews.

THE SECRETION OF URINE.

DURING the last few years the literature on the functions of the kidney has increased to such an extent that even those engaged in research find it difficult to keep in touch with all parts of the subject. It is not surprising, therefore, that Professor CUSHNY has had to read through more than six thousand pages of varied quality before writing his monograph on *The Secretion of Urine*.¹ In this small volume the different views on renal function are presented and discussed, and the facts on which those views are founded are set down apart from the discussion, "so that they at least may remain, whatever theory of kidney activity may survive."

Professor Cushny does not accept the theory that the constituents of the urine are secreted by the vital activity of the epithelium of the capsule and of the tubules. The theory advocated by him, and called by him the modern theory, is that with which his name is associated in the textbooks. He adopts Ludwig's view that the capsule acts as a filter, allowing all the constituents of the plasma to pass through it except the proteins, and that this filtrate is concentrated by reabsorption during its passage along the tubules. He, however, differs from Ludwig as to the way in which reabsorption is effected, for whereas Ludwig explained it as a passive diffusion, Professor Cushny holds that it is an "active absorption" entailing the expenditure of energy by the cells. The constituents of the plasma, according to him, fall into two main groups: (1) Substances, such as urea and sulphates, which are excreted in the urine as long as they are present in the blood; and (2) substances, like dextrose and chlorides, which are excreted only when they reach a certain threshold value in the plasma. The "threshold bodies" of this latter group are capable of absorption by the tubule cells in proportions determined by their normal values in the plasma, while the "no-threshold bodies" are rejected and escape by the ureter.

Briefly, the function of the kidney is defined as "the filtration of the non-colloid constituents (of the plasma) through the capsule, and the absorption of Locke's fluid through the tubule cells."

For the arguments in favour of this theory the reader must be referred to the book, in which all the important facts ascertained about renal activity are discussed in connexion with it.

The book is well arranged and full of information and suggestive ideas. It contains some useful diagrams, and there is a good bibliography. Even those who do not accept Professor Cushny's theory must admit that he has rendered great service by collecting and setting down so ably in this small volume the facts of renal secretion.

TWO GERMANS IN PARIS.

DR. CABANÈS, who is a diligent explorer of historical by-ways, has devoted the greater part of his most recent volume, entitled *Une Allemande à la Cour de France*,² to Elizabeth Charlotte, great granddaughter of James I, and niece of Sophia Duchess of Hanover, the mother of George I. She became the second wife of Monsieur, brother of Louis XIV, whose first wife had been Henrietta, daughter of Charles I. She was the daughter of the Elector Palatine, and in France was commonly called the Princess Palatine. She wrote to her relatives in Germany an immense number of very long letters, many of which have been printed, and it is from these that Dr. Cabanès has constructed his story. In spite of her lofty connexions she was a very gross person. The functions of the large intestine and the accidents that may attend its activities were a source of unflinching interest to her. Nevertheless she resented the frequent purgations and copious clysters

which, like the periodical bleedings, were the medical fashion of the day. Her remedy for most ills was to go for a long walk, and she rode to hounds in her early days. Apparently the King, his family, and his mistresses all had bad teeth, and no doubt pyorrhoea, for their mouths offended the senses of sight and smell. The court ate too much, and some of them drank too much, which may help to account for the purging and bleeding. Table manners were primitive; the fork was being introduced, but the Princess resented the innovation. "I have never," she wrote, "eaten with anything but my knife and my fingers." Fashions change, and it is now considered to be not quite good manners to eat pudding with a spoon, yet Mr. Gladstone once said that in his youth a fork was never used for this purpose; still it must have been a curious sight to see the Princess consume her favourite dish of smoked sausage and sauerkraut with fingers and knife. Was it fingers or knife that went into her mouth? She denounced some other innovations, as, for example, the use of tobacco by women, whether as snuff or in a pipe. Apparently the fashion of using snuff was well established among women in her day, and that of smoking a clay pipe not unknown. One of the many engravings Dr. Cabanès reproduces shows three fine ladies smoking churchwardens in an arbour. The Princess Palatine thought such women disgusting—stinking was her word—but held that women who did not wear corsets were on the road to ruin; which recalls Byron's opinion that a lady who waited could hardly hope to retain her virtue. Dr. Cabanès's essay contains much out of the way information, not a little of it medical, but we will mention only one other matter, though it may be more generally known than we suppose. During the last years of his life Louis XIV, gouty and otherwise crippled, did not care to try to walk; the wheeled chairs made for him became for a time popular with his courtiers, and seem to have been the forerunners of the bath chair.

In another essay Dr. Cabanès gives an account of Dr. Koreff, an enigmatic character, born in Silesia, M.D. of the University of Berlin, and reputed Austrian spy in Paris. He seems to have acquired a practice among fashionable women to which neither his skill, his manners, nor his appearance entitled him, and to have wormed or forced his way into the literary society of the Restoration and the reign of Louis Philippe. He won the confidence of Talleyrand, who said of him that he knew everything, even a little medicine. Talleyrand's daughter looked on him as a charlatan, others declared he was an abortionist, and the courts in 1837 found him an extortioner by awarding to him and one Wolowski 24,000 francs without costs in place of the 400,000 francs they had demanded for attending the Countess of Lincoln. Altogether Koreff, whether a spy or no, was an unsavoury person.

The volume also contains two short essays on Frederick the Great's minor accomplishments in the way of playing the flute and physicking himself and his friends, and on the manner of his death.

NOTES ON BOOKS.

CAPTAIN CHIODI'S practical manual of prophylaxis and disinfection³ for the use of the Italian army is a sound and sensible little book on military sanitation that should be of service to medical officers in the field. Being written in Italian, it is likely to be studied, alas! by but few British readers, and so will not receive an extended notice here.

The second edition of Baillière's *Popular Atlas of the Anatomy and Physiology of the Female Human Body*⁴ is an excellent specimen of British lithographic art. It should prove of great service to nurses, masseuses, and lectures on first aid, home nursing, and the like, to whose attention it may be cordially recommended. The explanatory letterpress leaves nothing to be desired.

¹ *The Secretion of Urine*. By Arthur R. Cushny, M.A., M.D., LL.D., F.R.S. London: Longmans, Green, and Co. 1917. (Med. 8vo, pp. xi + 241; 35 figures. 9s. net.)

² *Une Allemande à la Cour de France. La Princesse Palatine. Les Petits Talents du Grand Frédéric. Un Médecin Prussien, espion dans les Salons Romantiques*. By Dr. Cabanès. Paris: A. Michel. 1916. (Cr. 8vo, pp. 393; 85 gravures. Fr. 3.50.)

³ *Manuale Pratico di Profilassi e Disinfezione*. By Dott. Valfredo Chiodi, Capitano Medico. Milano: Ulrico Hoepli. 1917. (Fcap. 8vo, pp. ix + 196; 32 figures. L.4.50.)

⁴ *Baillière's Popular Atlas of the Anatomy and Physiology of the Female Human Body*. With descriptive text by Hubert E. J. Biss, M.A., M.D. Cantab. Second edition. Plates by Georges M. Dupuy, M.D. London: Baillière, Tindall, and Cox. 1917. (4s. net.)

In the *Prevention of Disease*⁵ Dr. WINSLOW has written a popular treatise on how to keep well and to avoid falling into disease. As is said in the preface, written by Dr. Charles H. Mayo, preventive medicine is in the ascendant nowadays. Much has been done to promote longevity by public health laws; Dr. Winslow's book may be recommended as an exposition of the laws of health for the individual.

⁵ *The Prevention of Disease. A Popular Treatise.* By Kenelm Winslow, B.A.S., M.D., Attending Physician to Seattle City Hospital and King County Hospital, Washington, etc. Philadelphia and London: W. B. Saunders Co. 1916. (Demy 8vo, pp. xv + 348; illustrated. 7s. 6d. net.)

THE PROPOSED MINISTRY OF HEALTH.

At a meeting at the Royal Institute of Public Health, on October 31st, Major the Hon. WALDORF ASTOR, M.P., delivered an address on "Health Problems and a State Ministry of Health."

The chair was taken by the Right Hon. H. A. L. FISHER, M.P., Minister for Education, who said that by degrees a public health conscience was being created in this country, and with the quickening of such a conscience there came the realization of the overlapping and confusion of functions which at present existed in the administrative departments dealing with health subjects. It was necessary to review all the agencies existing for the promotion of public health, and, if possible, to co-ordinate them into a more effective and economical system. The child came into the world under the aegis of the Central Midwives Board and the Lords of the Privy Council; a month or two after birth it received the care of voluntary associations who might or might not be subsidized either by the Board of Education or the Local Government Board; from a tender age up to 14 the child was under the supervision of the school medical service, which in its turn was controlled by the local education authorities and the Board of Education. All this time the Local Government Board had been exercising what constitutional lawyers called a residual sovereignty over the health of the child, and this came into evidence should the child be the victim of infectious disease. At 16 the child passed under the control of the Insurance Commissioners; if at work in a factory he was medically supervised by the Factory Department of the Home Office, unless it was a munition factory, in which case he came under the Ministry of Munitions. If disabled in the war, he was dealt with by the Local Pensions Committees and the Pensions Ministry, and, finally, if a pauper, his health was the solicitude of the Poor Law authorities. Mr. Fisher was not of opinion that a system was necessarily condemned by the fact that it entailed a certain amount of overlapping and confusion of functions. Administration was a very rough business, and no system, however scientifically controlled, was really adequate to meet all the casualties of human life. But there were limits to overlapping, and these in the sphere of public health had been overstepped.

Major ASTOR, in the course of his address, said that if a perfect State scheme were awaited, no beginning would ever be made. A comparatively small step forward in 1917 would be worth more than a profound consideration during the next year or two of ideals and theories unaccompanied by action. The first thing required was a central health department; the second, reform in the local areas. The disentangling of the spheres of labour of the sanitary and local education authorities, the boards of guardians, and the insurance and pensions committees was a problem which would become much easier when the great majority of these bodies could look to one common head. The creation of a new Ministry was theoretically the cleanest course, but he was inclined to accept the view that it was important to build upon the tradition and experience of an existing department. He trusted that the prejudice created by the Poor Law associations of the Local Government Board would not prove an insuperable obstacle, and he suggested that the Board be rechristened Ministry of Public Welfare and Local Government. If once such an amalgamation were established, the disentangling process could go forward, and the health powers of other departments be transferred gradually to the reconstituted ministry; ultimately the non-health functions of the Board could be given over to another department,

or the health section could break away and become independent. An attempt at co-ordination was evidently necessary. Mere consultation between departments was too often a euphemism for a protracted battle, resulting in inaction and disappointment. The existing overlapping at the centre was more responsible for the conditions of preventable disease and mortality than the lack of powers or an unwillingness to use them. He pleaded for such re-organization that existing powers could be exercised to the best advantage, and afterwards it would be possible to discuss at leisure what, if any, new and enlarged responsibilities should be assumed by the State.

In the discussion which followed, Mr. KINGSLEY WOOD, Chairman of the London Insurance Committee, urged the need for establishing a totally new Ministry to consolidate step by step the health functions of the Government, and expressed the belief that the substantial agreement which the Prime Minister had indicated as the condition of acceptance was being approached.

Dr. ALFRED COX said that long ago the medical profession, as represented by the British Medical Association, had endeavoured to get rid of the state of affairs to which the Minister for Education had called attention. The Association had considered the latest proposals for a Ministry of Health very carefully of late, and was taking steps to get in touch with other organizations in the hope of arriving at some understanding. He preferred the title "Ministry of Health" to "Ministry of Welfare" as being more simple and descriptive. Any proposal merely to take the Local Government Board and call it by another name would be looked upon askance by the great majority of the medical profession. Another thing upon which, he thought, the medical profession would lay a good deal of stress was the extension of domiciliary attendance, which, to be adequate, should develop the germ already in the insurance scheme so as to give every man a family doctor and admit him to the best specialist and institutional treatment of all kinds. He hoped also that in any Health Ministry which was set up nothing would be done, such as the starting of a whole-time State service, which would prejudice the large number of medical men at present out of the country.

Dr. J. HOWARTH, M.O.H. for the City of London, defended the Local Government Board, which, he said, had done more for the improvement of the community than any other department, and never had its activities been more pronounced than during the last ten years. It suffered, however, from an innate conservatism and the absence of some driving force. He suggested that it should be a real Board, not, indeed, of whole-time men such as had been appointed on the National Insurance Commission, nor of men elected by societies to promote some particular end, but of men of broad views, who should serve for five years, and should be overseers of the administration, advisers to the Minister, and educators of the public. The risk attaching to the setting up of absolutely new machinery would in that case be removed.

Sir BERTRAND DAWSON said that public opinion was ripe for some change, and professional opinion as well. Personally, he would rather have a Health Ministry, but, after all, it was the thing that mattered, not the form. If the proposal was to be a success it was necessary to unite the medical profession in its support. The Insurance Act appealed to the interests of the profession, but it never satisfied their ideals. He believed that the medical man of the future would be more concerned in promoting health than in curing disease; the treatment of disease in the home was becoming increasingly impracticable. Diagnosis and treatment had become team work, and the teams had to be formed and educated. He looked to an organization of preventive and curative medicine which would be a complete whole, from the big teaching hospitals and institutions at the centre to the village clinic at the periphery.

Dr. H. B. BRACKENBURY said that practically the whole profession distrusted the Local Government Board; the projected Ministry, whether organized on the basis of the present Board or not, should be a Ministry of Health, and that only. Dr. SMITH WHITAKER and Lieutenant-Colonel SPRINGTHORPE (Professor of Hygiene, Melbourne), also spoke, and Major ASTOR, in reply, said that doubtless they all seemed to be going to the same goal, but by different roads; there was some danger, however, lest they should be going on parallel roads and never meet.

British Medical Journal.

SATURDAY, NOVEMBER 10TH, 1917.

FLANDERS WEATHER.

IN recounting the gallant capture of Passchendaele village by the Canadians last Tuesday the correspondent of the *Times* spoke of himself as looking across a wilderness of mud and shell holes, and told how, having seen the signal rocket go up indicating that the village had been entered about 9 a.m., he spent much of the rest of the day in getting home, for, he wrote, "the covering of even a few miles of this shell-hole morass, with intervals of threading duckboards and slushing along the mud-swilled roads, is a matter of some hours." The sentence quoted may serve to remind us of the difficulties the Army Medical Service has had to meet in evacuating the wounded, during the last couple of months especially. Nevertheless we believe it to be correct to say that the field has usually been completely cleared within twelve hours of the beginning of each stage of the offensive, with the possible reservation that wounded men who have crept for shelter into isolated shell holes or dugouts may not be found until later.

The nature of the ground and the broken weather have combined to make the work very trying. The physical conditions, which, as was shown by accounts we published at the time, were very troublesome in the battle of Arras, have been reproduced in an aggravated form during the recent fighting further north. All the war correspondents refer to the difficulties of the Flanders advance owing to the state of the ground, and their accounts have been effectively supplemented by some of the pictures in recent issues of the illustrated weeklies. They give a good idea of the water-logged shell-pitted surface of the western side of the Passchendaele-Messines ridge; but some imagination is needed to realize the depth and stickiness of the mud and the amount of twisting and winding imposed on stretcher-bearer parties by the dangerous depth of many of the pools. But for the use of corduroy tracks and duckboard paths rapid clearance of the field of action would, as things now are in Flanders, be practically impossible, and even with their help, courage, endurance, and a strong sense of duty are necessary to its successful achievement.

In organizing lines of evacuation the permanent roads must be supplemented by temporary tracks. A corduroy road is built up of baulks of timber about 9 in. broad and 4 in. thick, laid side by side and clamped to longitudinal baulks of timber by iron riveting pins. Such roads are among the first signs of extending civilization in Canada, and colonial troops show special skill in laying these tracks rapidly. The duckboards are constructed on the same principle as the wooden gratings often used in sculleries and laundries. They consist of slips of board about 2 in. wide, fixed at intervals of an inch or two on longitudinal laths. They are made in sections, and can easily be shifted. In trench warfare, as was fully explained in illustrated articles published in recent issues of the *JOURNAL*, it may be possible for stretcher-bearers to get the wounded along the trenches—which, as a rule, are floored with duckboard—to the head of the evacuating line, but when there has been an advance the wounded may

have to be got across more or less open country, where there may be no paths, or only very rough tracks. The strain upon the bearers is very severe, and it may be necessary to employ as many as eight bearers to carry a single patient a couple of miles. If the R.A.M.C. officers in such circumstances had none but the ordinary regimental stretcher-bearers and the bearer sections of field ambulances at their disposal, it would be impossible to "clean up" the field of action quickly. But this fact has been more and more recognized by army commanders since Festubert, some two and a half years ago, and extra men are detailed to act as bearers. When the carry is long the distance is divided up and relay posts established, at each of which there is a squad of stretcher-bearers. Each squad having taken its burden to the nearest relay post hands it over to the next squad, and returns to the post whence it started. The first relay posts receive their wounded from a varying number of regimental aid posts with which they are in touch, and the last relay squad takes its stretcher burden to a place at which horse-driven or motor ambulances can be brought up and loaded, or to which light wheeled ambulances, or stretcher carriers running on tramways can be brought; these types of light ambulance have been illustrated in the *JOURNAL* (June 2nd and August 18th). This part of the zone of combat being within the sphere of the field ambulance, the relay posts will usually be in charge of the field ambulance medical officers. Walking cases finding their way to the rear by the corduroy roads or other tracks mentioned, are at certain points deflected to places where they can be picked up by vehicles of various sorts which can be made available for the purpose.

It is obvious that men engaged in transporting the wounded from the regimental aid posts to the head of the evacuating line may have to traverse areas exposed to shell fire and to the attacks of snipers and even of machine-gun parties, and such risks may not be over when the organized evacuating lines have been reached. Apart from the risk, the labour is extremely severe, since a man whose uniform is soaked in mud and water is a heavy burden; duckboard sections are apt to be very slippery and may become displaced, and corduroy roads afford very uncertain footing unless freshly swept clean of mud by heavy rain. This will help to explain why neither the French military authorities nor our own have ever agreed with the popular idea that the rank and file of the medical services can safely be recruited, to more than a small extent, from men who are physical weaklings. The French army regulations for the guidance of recruiting officers, in fact, specifically lay down that men for the *Service de Santé* must be chosen from those deemed fit for general service of all kinds. The exhausting character of the work also explains the practice, in both armies, of withdrawing field ambulances for rest, and replacing them by others at the close of any heavy offensive. In a heavy offensive on a short front it may be necessary to employ several field ambulances or their French equivalents to work together in this advanced part of the zone, but in that case the need for withdrawal is not diminished, but affects a larger number of units.

The way in which the wounded after reaching the advanced dressing stations are taken further to the rear has often been explained, and though it has been improved it has not, we believe, altered in principle. Stretcher cases usually continue their journey in motor ambulances, walking cases either in lorries or in trucks on broad or narrow gauge lines. The

objection to the use of such lines is that ambulance vehicles upon them may be subjected to long delays, and in any case do not usually travel nearly so fast as a motor ambulance on a decent road. The steam tractors used on the narrow gauge lines are protected by steel plating, but they seem rather apt to get off the line, which is, of course, when first put down roughly laid, and this must involve delay. The stretcher-carrying lorries on trench tramway lines and their continuations, which have been illustrated in previous issues, are very useful. The lines are very like those to be seen in the neighbourhood of any quarry in this country, and consist of light steel rails bolted together by small fish-plates.

Given similar terrain, the general principles on which evacuation of the wounded is carried out cannot vary very much, but the details have to be worked out separately for each section. This responsibility falls upon the D.D.M.S. of the army corps, who must consider beforehand what arrangements will best meet the situation that may be expected to result from the operations the divisions of his corps are about to undertake. Among the considerations he has to keep in mind are the general lie of the ground and the state of its surface, the number and condition of the permanent roads, corduroy tracks, or duckboard paths by which it is traversed, the number and availability of the trench tramway lines, and the selection of places where car-loading points or advanced dressing stations can be established, as well as the distance of the objective from the assembly trenches and the jumping-off point. His arrangements may at any time be disturbed by the destruction of a portion of a tramway or the heavy shelling of a section of an evacuating line, or, again, by the occurrence of a large number of casualties at an unexpected point.

The aim of a D.D.M.S., as also of A.D.M.S.'s of divisions and of all medical officers in front of the casualty clearing stations, is to secure rapidity in the removal of casualties, so far as is consistent with the well-being of the patients; and in view of possible interruption or accumulations it becomes the duty of a D.D.M.S. of a corps in action to duplicate his arrangements as far as possible, so that when one line of evacuation fails or becomes encumbered another shall be immediately available. The D.M.S. of the army engaged is not only responsible generally for all these arrangements, but also for the placing and organization of the casualty clearing stations, so that they shall be sufficiently numerous, sufficiently officered, and suitably placed in relation to the evacuating railways. Foresight and a capacity for minute attention to details of organization are necessary to secure success in evacuation work, especially under such conditions as have been prevailing in Flanders recently. Hardly less important is it that the men chosen for such positions as D.M.S., D.D.M.S., and A.D.M.S. shall be capable of winning the ready co-operation of the combatants with whom they are brought into contact, and of maintaining the right spirit among their own subordinates; events up to the present demonstrate that in the task of selecting such men, and of making them feel that boldness of design, coupled with careful attention to detail and energetic action, will always meet with his support, Sir Arthur Sloggett has been singularly successful. Much the same remarks might be made of the work on the lines of communication and at the bases, but with this we are not for the moment particularly concerned. It is practically unaffected by the weather conditions at the front or the nature of the ground on which the recurring actions are fought.

TUBERCULOSIS INSURANCE IN THEORY AND IN PRACTICE.

CRITICISM of English institutions by experts from other parts of the empire is always welcome and often refreshing. Opportunities for study of such institutions from within are rare. An appointment as tuberculosis officer to the borough of Middlesbrough has given such an opportunity to Dr. H. A. Ellis, who, with thirty years' experience of tuberculosis in Australia, is able to approach the subject without any preconceived notions as to the perfection of home methods. His official reports for the last two years have been commented upon from time to time.¹ At the recent annual meeting of the National Association of Insurance Committees he read a paper containing an interesting analytical summary of results achieved in proportion to the amount of money expended. Dealing only with insured cases, he asked how the limited funds provided by the Insurance Acts could be applied so as to achieve the best possible results. It is admitted that the amount at present provided is only sufficient to enable a part of the work to be carried out.

Approaching the subject from a purely business point of view, and ignoring for a time the humanitarian side, he showed that money spent on incurable cases is doubly wasted. The patient receives no lasting benefit, and is of no economic value to the community. The same sum might have enabled a curable case to recover health and economic usefulness. The authorities of Middlesbrough have acted upon these lines with most satisfactory results. Since the introduction of the system of priority for early cases, the percentage of success in the restoration of working capacity has been raised from 26 per cent. in the years 1913-14 to 69 per cent. in 1915-16. By a calculation made from the actual figures it was shown that with a wage-earning capacity of 30s. a week, the wage value during the first two years was £2,730, attained at a sanatorium cost of £1,008, whereas during the latter period, curable cases alone being treated, a wage value of £2,574 was obtained at a cost of £370. Grants for extra nourishment always loom large in tuberculosis accounts. As applied to advanced cases such grants yield no return, but they are of actual economic value when judiciously used to aid real recovery.

Dr. Ellis recorded very gratifying results from domestic treatment. Even in the least satisfactory environment the recuperative power possessed by many incipient consumptives, he said, was remarkable, and in most cases the patients were willing and anxious to carry out directions. The possibility of sanatorium treatment as an alternative doubtless operates in favour of obedience to the rules laid down for home treatment. Dr. Ellis, however, did not lay so much stress upon unsatisfactory environment as upon careless habits of life, and working overtime or under stress of recent illness. Home treatment was mainly directed against these three factors, but especially against overtime. In the vast majority of instances it was found that the natural resistance of the individual, rightly guided, was a sufficient protection against the progress of the disease. Turning to the study of the death-rate from tuberculosis for the borough of Middlesbrough, he emphasized the fact that the great majority of deaths occurred shortly after notification, and that the rate became lower among notified cases with each succeeding year. In the three years since January, 1914, there were 205 deaths of insured persons, and of these no fewer than

¹ BRITISH MEDICAL JOURNAL, October 7th, 1916, and July 14th, 1917.

158 occurred within a year of notification, and 115 of them during the first six months. The acute tuberculous affections of childhood and youth under 16 years of age were not included in these statistics.

It seems clear that far more stringent application of the notification rules is called for, and probably in very many boroughs other than Middlesbrough. Possibly the system which is in vogue in some districts, of diagnosing tuberculosis only after detection of bacilli in the sputum, may be responsible for some of the delay in notification. If so, it calls for prompt alteration, as it effectually lessens the patient's chance of real recovery. Early diagnosis, although it may entail expense and may sometimes prove incorrect, is essential for success in the great majority of cases. Up to the present time there has not been sufficient co-ordination of method, either of treatment or of statistical information. A reform of the present system of notification is needed to render it complete and effective. Under a uniform system of reporting it would be possible to make more practical distinction between home and sanatorium cases, and much more accommodation in sanatoriums would doubtless be available if this were done. Comparison of results also would enable some idea to be formed of the actual return in proportion to expenditure.

Some form of central control is needed not only to check individual extravagance but also to direct available funds into the most useful channels. Dr. Ellis considers that the cumbrous machinery which has been employed up to the present time to deal with tuberculosis, consisting of the Local Government Board, the county councils, the borough councils, and the Insurance Committees, local and central, is not fitted to cope with such a many-sided problem; he advocates the establishment of a permanent committee, consisting of business men as well as experts. His outspoken comments upon the whole subject deserve very careful consideration.

MEDICAL ASSESSORS.

An order has been made which provides generally that the functions of the Army Council in relation to the work of tribunals shall in future be undertaken by the Minister of National Service. Military representatives have now become National Service representatives, and directions will be issued to them that in dealing with cases before tribunals they must have regard to the need of men not only for the army, but also for other urgent national requirements. Special medical boards have ceased to exist. The Local Government Board, which is now responsible for the work of appeal tribunals and medical assessors, has issued two pamphlets¹ containing rules and notes for their guidance. The rules deal with the re-examination and grading of men for military service, and the notes with the functions of appeal tribunals and medical assessors. They provide that any man may apply to the appeal tribunal within a stipulated period of time (five days) against his grading by the National Service Medical Board, or if he has applied to the National Service Medical Board for a re-examination and has been refused, against that refusal. The appeal tribunal, if satisfied that he has made out a sufficient case, may authorize him to be re-examined by their medical assessors. Medical assessors will be appointed at eleven centres in England and Wales by the Local Government Board, and at three centres in Scotland by the Scottish Office. The centres in England and Wales are Newcastle-on-Tyne, Leeds, Sheffield, Manchester, Liverpool, Birmingham, Norwich, London, Bristol, Exeter,

Cardiff. Each appeal tribunal or separate section of an appeal tribunal in England and Wales will be associated with one of the groups of medical assessors. In order to simplify procedure it has been provided that all applications must be made directly to the appeal tribunals. Local tribunals will not have authority to consider applications for medical re-examination or to refer men to medical assessors, but they will have power to adjourn the hearing of a case in order that the man may apply to be re-examined by the National Service Medical Board. It is intended that the medical assessors shall have the use of the premises and clerical staff of the local National Service Medical Board. The premises must afford ready facilities for consultations between the medical assessors, and reasonable privacy for the men examined, as well as a good waiting-room. The Advisory Medical Board for England and Wales, appointed by the Local Government Board in consultation with the Central Medical War Committee and the Minister of National Service, will act for the two departments, which in this way will hope to keep in close touch with the medical profession. The Local Government Board will consult the Advisory Board on all important medical matters, and will refer to it any important medical question raised by medical assessors. The constitution of the similar Board for Scotland is announced elsewhere in this issue. Before a man is finally graded his case must be considered by at least three medical assessors and his grade settled in consultation. One of the medical assessors in each group will be formally appointed as the medical assessor in charge. It is pointed out that a man who has made application for re-examination will usually base his claim on certificates from private medical practitioners, and due regard must be paid to such certificates by the appeal tribunal and the medical assessors. The certificates will assist the assessors by indicating matters to which their examination should be particularly directed, but their value will depend on the extent to which they state matters of fact as distinct from mere expressions of opinion. Before examining a man the medical assessors must obtain from the Assistant Director of Recruiting the medical history sheet of the man prepared by the National Service Medical Board, and when the medical assessors have decided on a man's grading they will record their findings on the medical history sheet, stating their reasons if the grading by the National Service Medical Board is altered. Medical assessors are advised that they will doubtless find it advantageous in some cases to consult, either personally or by letter, the chairman of the National Service Medical Board by which the man was originally graded. In order to prevent personation medical assessors are directed when necessary to require a man to sign his name in their presence, and to compare it with his previous signatures on his grade card and the counterfoil and on his registration certificate, and also to check the height and other identification particulars on his medical history sheet. The executive officer of the medical assessors will be secretary or clerk of the appeal tribunal; under the executive officer there will be a clerk in charge, who will obtain the medical history sheet as soon as he receives the authority from the appeal tribunal for the medical re-examination of a man. There should be no avoidable delay in summoning a man, and notice should be sent to him at least three clear days before the examination. It is expected that twenty will, on the average, be examined at each session, and more should not be summoned.

STATISTICAL WIREPULLING.

Many of our readers have been favoured during the last few days with a pamphlet written by Dr. Walter R. Hadwen and circulated by the British Union, under the title, "Registrar-General's Statistics: some interesting figures showing how and why certain important diseases have increased or decreased during the last fifteen years."

¹(R. 156 and R. 157.) London: His Majesty's Stationery Office. Price 1d. each.

The "British Union" is the British Union for the Abolition of Vivisection, though that fact does not appear on the title page of the pamphlet. With the general method adopted by Dr. Hadwen and his friends our readers are sufficiently familiar. If the death-rate of a disease such as scarlet fever, the bacteriology of which is obscure, has declined, the result is claimed as showing "what sanitation can do when not interfered with by vaccines or serums." If some other disease of similarly obscure causation (such as measles, the death-rate from which was 277 per million in 1901, 275 in 1906, 363 in 1911, and 462 in 1915) has not declined, nothing is said about it. When, on the other hand, the mortality of such a disease as diphtheria has declined, laboured attempts are made to prove that antitoxin can have had nothing to do with the change. With this apology for reasoning, by means of which we could "prove" that the increased circulation of halfpenny newspapers has increased the numbers of deaths from cancer, we need not deal; but we shall refer to two instances which well illustrate Dr. Hadwen's competence to instruct the lay reader in medical statistics and the standard of controversial ethics to which he conforms. On the first page of his pamphlet he gives the absolute numbers of deaths from anthrax for each year from 1901 to 1915. He remarks: "It is thus seen that the number of deaths in 1915 is double that of fifteen years ago. The average number of deaths per annum before the serum was introduced in 1899 was only eight. This speaks for itself." For the period prior to 1899, as Dr. Hadwen does not state how many years have been averaged, we cannot check his figure, but statistically, the point is that the variability of the annual numbers must be large, since the absolute number is small and the incidence of the disease is upon a population of millions; the death-rate is therefore minute. Roughly, the measure of reliability of a rate varies as the square root of the number. Taking the annual average of 16.13, we should quite often expect fluctuations of as much as 5 or 6 either way, and it is an even chance that there will be a fluctuation of 2.7 or more either way. The only large variations from the mean value are in 1905 and 1906 (24 and 26 cases), and again in 1915 (24 cases). Dr. Hadwen deliberately contrasts the latter figure with the 12 cases of 1901. Moreover he does not mention the fact that several recent cases of anthrax have been traced to the importation of infected hair which was the subject of a special inquiry carried out by the Local Government Board. The attempt to convey to the reader the impression that anthrax is steadily increasing, doubling itself in fifteen years, is a lamentable example of statistical incompetence and controversial blindness. On p. 8 of his pamphlet Dr. Hadwen gives the recorded deaths from syphilis, and insinuates that the death-rate has been rising since salvarsan came into use. Unskilled as he may be in statistical methods, he must be aware that the Registrar-General (in the official evidence submitted to the Royal Commission on Venereal Diseases and elsewhere) has frequently warned the reader that the official statistics of deaths from venereal diseases are seriously incomplete, and only to be used with the utmost caution. This does not deter Dr. Hadwen from writing: "National insurance money has actually been used for the purpose of inventing and manufacturing imitations of this dangerous drug (salvarsan), and there is no question that behind all the morbid sensationalism artificially created in regard to the treatment of this disease, at public expense, lies the wire-pulling of commercial interests." The concealment of wires behind morbid sensationalism is a method of rhetorical camouflage which is not easy to comprehend, but that one member of an honourable profession should aim such a taunt as this at those of his professional colleagues who have had the duty of advising the Government upon a serious problem, is a painful instance of the depths to which a controversialist may descend. We do not suppose that any persons of average intelligence

will be disturbed by Dr. Hadwen's utterances, but they have a certain value in the light they throw upon the psychology of the supporters of the British Union for the Abolition of Vivisection.

THE SINKING OF HOSPITAL SHIPS.

BEFORE the war many of those best qualified to judge the stage of culture reached by the German people, and especially the North German people and their rulers, believed that it was essentially behind that attained by the Western peoples. It was believed that though they had learnt to use the methods and machinery of science, they had not assimilated the higher mental and spiritual qualities developed by the civilization of the more advanced nations. This opinion has unfortunately been only too amply confirmed by a large mass of evidence. One of the earliest pieces of evidence was the manifesto of the intellectuals, which perhaps impressed upon the minds of the intellectual classes in other countries the low standard of German culture more than even the atrocities committed by the orders of the military chiefs. The Germans share with the lower races of mankind a certain cunning which is being exhibited at the present time in many directions. One example is their practice of preceding each fresh iniquity by lying statements; they speak, for example, of seaside resorts as ports, and open towns as fortified places before they bombard the one or drop bombs on the other. In pursuance of this policy, before they began torpedoing hospital ships they transmitted through the American Ambassador a memorandum (January 28th, 1917) respecting the misuse of hospital ships, which was a tissue of falsehoods, purporting to be backed up by scraps of hearsay evidence which would not have been accepted in a court of law as evidence against a pickpocket. The memorandum and so-called evidence on which it rests have now been published in a White Paper,¹ together with a detailed reply on each point and a note by the Foreign Secretary dealing both with the original memorandum and with a later memorandum (March 29th) received through the Netherlands Government. A categorical denial was issued by the British Government at the time, and Mr. Balfour expresses the hope that the German Government will, now that the value of the evidence on which it relied has been demonstrated to the meanest capacity, have the sense to withdraw the false charges it has made regarding the misuse of British hospital ships and give unconditional instructions to its naval forces to grant these vessels in the future the immunities due to them under the provisions of international law. British hospital ships have never been used for the carriage of munitions of war or of combatant troops; Red Cross stores and personnel of the Royal Army Medical Corps (who are protected by the Geneva Convention) have been embarked, and it is thought probable that the German Government may have been misled by the fallacious deductions of their witnesses, who apparently were unable to verify their assumption that cases of Red Cross stores were really munitions of war, and bodies of the Royal Army Medical Corps in khaki uniforms detachments of combatant troops. No British hospital ship has ever embarked any persons but invalids and hospital staff. The German Government in its second memorandum tried to make out that though the allegation as to the carriage of troops had been denied, that as to the carriage of munitions had not been denied. This is founded upon the terms of an official denial by the British Government of a particular story of one Albert Messany, a Viennese opera singer, which is shown to be a tissue of falsehoods. The White Paper points out that "the play which the German Government make with this imaginary discrepancy is an illustration of their practice of trying to make capital out of infinitesimal points, a practice which has the appearance of being adopted in order to cover up the weakness of their main position."

CONJOINT BOARD OF SCIENTIFIC STUDIES.

The first annual report of the Conjoint Board of Scientific Studies, established at the instance of the Council of the Royal Society in June, 1916, has been issued. The objects of the Board are to promote the co-operation of those interested in pure or applied science; to supply means by which the scientific opinion of the country on matters relating to science, industry, and education, may find effective expression; to promote the application of science to industries and the service of the nation; and to discuss scientific questions in which international co-operation seems advisable. The Chairman of the Board, which consists of representatives of numerous societies, is the President of the Royal Society. Among the constituent societies are the Royal Anthropological Institute, the Royal Colleges of Physicians and Surgeons in England, the Royal Society of Medicine, the Pharmaceutical Society of Great Britain, the Psychological, Linnean, Zoological, Biochemical, and Psychological Societies, the Institute of Chemistry, the Society of Chemical Industry, the Chemical Society, and the Royal Institute of British Architects. There is a small executive committee, of which Sir Joseph J. Thomson, President of the Royal Society, is chairman, and Dr. W. W. Watts, Professor of Geology in the Imperial College of Science and Technology, secretary; among the other members are Sir Alfred Keogh and Sir Ray Lankester. The board has appointed a number of subcommittees, some of which appear to have got to work during the year, including the International Catalogue Subcommittee, which has obtained information regarding the extent of the use made by scientific men of the present International Catalogue of Scientific Literature; the Watching Subcommittee on Education, of which Sir Ray Lankester is convener, the Metric System Subcommittee, and the Anthropological Survey Subcommittee. The last named consists of Major Leonard Darwin (convener), Professor A. Keith (secretary), Dr. James Galloway, Dr. P. Chalmers Mitchell, and Professors G. Elliot Smith, Karl Pearson, and Arthur Thomson. It has presented a report on the need of a physical survey of the British people, and intends to institute further inquiries before drafting recommendations. On its advice the executive committee asked the Board of Education, the Local Government Board, and the Registrar-General's Office to nominate representatives on the subcommittee, and Sir George Newman, Sir Arthur News-holme, and Dr. T. H. C. Stevenson, have been appointed. The Watching Subcommittee on Education has held a conference with the Council of Humanistic Studies, and has made a report to the Conjoint Board, in the course of which it recommended that both natural science and literary subjects should be taught to all pupils below the age of 16, and that afterwards specialization should be gradual and not complete. It points out that in many schools of the older type more time, which can often be obtained by economy in the time allotted to classics, is needed for instruction in natural science, but that in many schools more time is needed for instruction in languages, history, and geography. The opinion is also expressed that while it is impossible and undesirable to provide instruction in both Latin and Greek in all secondary schools, provision should be made in every area for teaching these subjects. The subcommittee also transmitted to the Government Committee on Science in the Educational System of Great Britain, two recommendations on which it was unanimous; one is that in order to secure teachers able to give inspiring and attractive courses in science adequate salaries should be paid, and the other, that while prime importance must be attached to provision for laboratory work it was essential that there should be instruction also in the romance of scientific discovery and its applications. Every pupil should not only receive training in observational and experimental science, but should be given a view of natural science as a whole, the object being

to evoke interest in science in relation to ordinary life, "rather than to impart facts or data of science presented by an examination syllabus, or even to systematize their rediscovery."

THE LABOUR PARTY AND THE MEDICAL PROFESSION.

AN interesting story is current with regard to the proposal now before the Labour Party to enlarge its borders so as to bring into membership "producers by brain" as well as "producers by hand." This story is that the Labour Party candidates at the next general election will include ten or a dozen medical men pledged to support a scheme for a State medical service. The rumour may be justified by events, but an examination of circumstances shows that at present it can be only a speculation as to what may happen. In the first place, it should be noticed that the proposal of the Labour Party executive for widening the constitution of the party is only a recommendation, and although it will probably be adopted at the conference which will take place at the end of January, the decision has still to be made. Secondly, it depends on this or succeeding conferences to determine what the programme of the Labour Party for the next general election shall be. Consequently, the question whether a State medical service shall be advocated by Labour candidates will in turn depend upon whether such a system shall be approved by the conference as a part of its programme, or, alternatively, upon the latitude to be given to Labour Party candidates who may come forward under a new constitution. There is very little doubt, however, that the reorganization of the party on the broader basis will be determined upon. It is probably on this account that Mr. Arthur Henderson, when he left the War Cabinet, preferred to keep the secretaryship of the party rather than resume its leadership, his wish being to attend to the organization in view of coming developments. He is at present giving all his time to this work in the office in Victoria Street, and in going up and down the country. So far the programme of the party for the next general election rests upon the resolutions passed at the Labour Conference in Manchester last January, and in these there is nothing about a Ministry of Health or State medical service. Meanwhile, of course, various groups are looking ahead; and it would not be surprising to hear that a number of doctors, more especially those who are members of the Fabian Society, should be taking informal action with the object of getting the question of a State medical service brought before the conference, and of suggesting that a certain number of medical men, if the Labour Party constitution is enlarged, should be included in the roll of parliamentary candidates for the next general election. There is talk of three hundred candidates being brought forward by the Labour Party. That, of course, must depend to some extent on ways and means; but with enlargement of constitution the "means" will doubtless enlarge, and the Reform Bill, by reducing expenses, will make candidature easier. But nothing has been settled.

THE REMUNERATION OF RURAL PRACTITIONERS.

THERE are two statements in a letter by "A Country Doctor," published under this heading at p. 633, upon which more light seems to be required. The first is that the fee for attendance on discharged soldiers and sailors and temporary residents is unremunerative. Assuming our correspondent's estimate of his travelling expenses in visiting the particular patient he instances to be correct, there is no doubt that his visits to this patient are unremunerative. If he has any real remuneration for attending such cases it must be that the majority live much nearer to him, so that, on the average, it costs him less in travelling expenses than he receives for attendance. The question whether this is economically a sound basis of remuneration is open to argument, but it certainly

seems to put an undue share of the risk on the shoulders of the medical practitioner, especially the rural practitioner, at the present time. At the conference of Local Medical and Panel Committees on October 18th the position of the rural practitioner was fully debated, and strong objection was taken to the mileage allowances offered for attendance on discharged disabled sailors and soldiers. The Insurance Acts Committee was instructed to press for the same scale of payment as that allowed for attendance on serving soldiers, and we understand that urgent representations to this effect have already been made to the Commissioners by the Committee. With regard to mileage generally under the Insurance Acts, the Insurance Acts Committee was instructed to press for an increased grant to rural practitioners. The other point in our correspondent's letter upon which further light seems to be required is his assertion that though his practice, as a country practice, may be called good, with every economy he could not live if he had not private resources. The general applicability of such a statement must depend, of course, largely upon the standard of living, which varies with each man. We are aware that for many years past some in a position to form a competent opinion have advised that no man should enter the medical profession who has not got some private means, but we did not know that matters had gone so far that a country practitioner could not live upon the receipts of his practice. We are quite aware that it is often a tight fit, particularly when children are growing up; the increased cost of living during the last few years must often have made the adjustment of receipts and expenses more difficult. It is now recognized that a medical practitioner is justified in increasing his fees to private patients, but the private patient of small means is disposed to argue that the same economic changes that are embarrassing the doctor embarrass him also. Moreover, not a few such private patients have become official patients. The profession is in a vicious circle, and we do not profess to be able confidently to point out the way of escape, but that the matter deserves very serious consideration is not doubtful.

A NEW JOURNAL OF NEUROLOGY AND PSYCHIATRY.

A new journal of neurology and psychiatry¹ in three languages—German, French, and Italian—has recently appeared under the direction of that eminent authority, C. Von Monakow, Professor of Neurology in the University of Zurich, with the collaboration of all the well known Swiss neurologists and psychiatrists. The assistant editors in neurology are Dr. Bing (Basel), Dr. Minkowski (Zurich), and Dr. Naville (Geneva); in psychiatry, Professor Dr. Weber (Geneva) and Professor Dr. Maier (Zurich). The second part of the first volume contains several important and interesting communications. Dr. Boissard records his researches on the behaviour of the leucocytes in genuine epilepsy; Dr. Naville publishes two communications upon amaurotic idiocy (Tay-Sachs' disease), and a note also upon an exceptional case of unilateral myopathy. Dr. H. Uemura, who has been working under Professor Monakow's direction, concludes an important paper upon the connecting paths between the stem of the brain and the cerebellum. This part contains also an experimental study of the physiology of the Rolandic and parietal convulsions by Dr. Minkowski, and the volume concludes with a review by Dr. Bing of German opinions upon the nervous accidents determined by the explosion of projectiles without evidence of visible injury. The volume is admirably printed and illustrated, and the matter contained upholds the deservedly high reputation which Swiss neurology has attained. This journal should be read by all neurologists and psychiatrists.

INTERNATIONAL SOCIETY OF SURGERY.

At a meeting of the Société Internationale de Chirurgie in Paris on November 3rd, 1917, which was attended by delegates from Belgium, France, Great Britain, Serbia, and the United States, it was resolved to dissolve the society after the publication of the volume of *Transactions* of the meeting held in New York on April 14th, 1914. It was further resolved that, should there be any assets after the publication of this volume, the money shall be divided *pro rata* amongst the members, so that each member of the Germano-Austrian group shall receive his share, but that the shares belonging to members of other nations shall be retained and applied to some object of scientific reparation in Belgium. The meeting then determined that a new society shall be formed after the war on a basis similar to that of the Société Internationale de Chirurgie. It will be called the Société Interalliée de Chirurgie, but will be open also to such surgeons of neutral countries as may be nominated for election by the general committee.

Medical Notes in Parliament.

Army Medical Services in France.

In the course of the debate on the Consolidated Fund Bill in the House of Commons, on Tuesday, Major David Davies asked whether the report of the Committee appointed to inquire as to the Army Medical Service in France would be presented to the House of Commons or treated as a confidential report to the Secretary for War; also as to the qualifications of the chairman. The gallant officer given this office had apparently retired from the service in 1909, but became Inspector of Infantry from 1914-15, when he again retired from the army, being at that time, it appeared, over 70 years of age. Major Davies further submitted that there could be no permanent improvement in the Royal Army Medical Corps until the Director-General was placed on the Army Council. It was useless to say that Sir Alfred Keogh had access whenever he liked, for all knew that when questions concerning medical matters were being discussed at the Army Council the Director-General of the Medical Service was not necessarily there, and had no right to be there, to give expression to his views. It was true that in 1904 Lord Esher's Committee reported that for financial and other reasons the Director-General of Medical Services should be placed under the Adjutant-General, but Lord Esher in a recent letter subsequently had written: "How much of the suffering undergone by our soldiers was due to the shortsightedness of my committee will never be known."

Mr. Macpherson said that until the report of the Committee of Inquiry had been received and considered by the Army Council he could not say whether or not it would be presented to the House. The Chairman of the Committee had had a distinguished career. It was true he was somewhat old, but in certain cases old age was no crime, and he was sure that the distinguished officer, who was perfectly fit and healthy, was capable, with all his knowledge and experience, of presiding over the Committee. Those who knew the composition of this Committee would realize that it was not a Committee appointed to white-wash anybody. The members of it would not be corrupted even by titles. As to the demand that the Director-General of Army Medical Service should have a position on the Army Council, Mr. Macpherson said that he accepted the report of Lord Esher's Committee, particularly as he knew that if in any given case on any important problem the experience of the Director-General was necessary for the Army Council he was welcomed, and every opportunity was given to him of stating his case.

Sir William Babbie: Army Council's Decision.

In the course of the debate on the Consolidated Fund Bill in the Commons, on Tuesday, Major David Davies followed up some questions he had addressed to the Under Secretary for War by further inquiries as to the circumstances of the reinstatement of Surgeon-General Sir William Babbie as Director of Medical Services at the War Office. Mr. Macpherson had stated earlier that, after the appearance of the Mesopotamia Commission Report, Sir William was given leave pending its consideration. He

was invited to submit an explanation; this was found by the Army Council to be satisfactory, and he was recalled from leave to resume his official duties. Mr. Macpherson had previously intimated that, for reasons for which the parties concerned were not to blame, the explanations of other officers mentioned in the Mesopotamia Report had not yet been available for consideration by the Army Council. Major Davies, recalling these answers, asked Mr. Macpherson if he could say who was responsible for the breakdown in the medical service in the Mesopotamia campaign. Did the reinstatement of Sir William indicate that the responsibility rested with Lord Hardinge or with the other medical officers, or did it concern the officers who held office in the Indian Medical Service before the war?

Mr. Macpherson, in a reply covering also other matters raised in the debate, said it would be remembered that in the Mesopotamia Report there was what lawyers called a saving clause so far as Sir William Babbie was concerned. It was made perfectly plain by the Commission that if it was possible to utilize the services of Sir William Babbie in any high appointment they could have no possible objection to his services being so used. The Army Council had a right by military law to ask of any officer an explanation of his conduct before he was dismissed or if they intended to dismiss him. In this case the Council exercised its right and had before it Sir William Babbie's explanation. It had in mind at the same time the recommendations of the Mesopotamia Commission. After perusing Sir William Babbie's explanation of his conduct the Army Council was unanimously of opinion that it would be a great detriment to the public military service of this country if it were deprived of the continued service of Sir William Babbie. Consequently the Council, as was its right, asked Sir William to come back to carry on the work which he was doing at the War Office, and was doing exceedingly well. Mr. Macpherson added he was certain that any soldier with any knowledge of the work of the Army Medical Service in any of the campaigns with which Sir William Babbie's name had been associated would be of the opinion that the Army Council took right and proper action to continue to use the excellent services of a most distinguished servant of the State. Replying to an interjection by Mr. Hogge, as to why the explanation of Sir William Babbie could not be given to the House, Mr. Macpherson replied that Sir William was content to leave the matter as it stood. The Army Council had never published explanations submitted to it by officers. On a further question by Major Davies as to why the explanations of the other officers were not available, Mr. Macpherson said that having regard to the persistent interruption he would state what was the fact. Sir William Babbie was directly under the Imperial Army. Some of the officers were not, and the question arose whether the Indian Government should take action in the case of two very distinguished Indian officers, Sir John Dixon and Sir Beauchamp Duff, or whether the Army Council should take action. That case was submitted to the Law Officers, who took time to consider the rather difficult and technical point, and that was how the delay arose. These two gallant officers were willing and anxious to have an opportunity at once of sending explanations to the Army Council.

Training of Military Medical Officers.—Major David Davies asked whether medical men who joined the Royal Army Medical Corps were compelled to undergo a course of instruction in drill before they began their clinical duties; if so, what was the period given to this course of instruction; and whether, in view of the shortage of medical men, arrangements would be made to allow these medical officers to proceed to their clinical duties without the delay caused by this instruction. Mr. Macpherson replied: Medical men commissioned as officers in the Royal Army Medical Corps undergo a short course of instruction in their military duties, and much importance is attached to this training, which is not confined to drill, but includes military sanitation, anti-gas protection, and the duties of a medical officer with troops in the field. It is not proposed to abolish this special training, which is considered essential to the efficiency of the officers concerned. In reply to another question, Mr. Macpherson said that the present status of the Director-General of the Army Medical Service did not come within the scope of the inquiry now proceeding as to medical arrangements for the British armies in France.

The Medical Re-examination of Recruits.—The Select Committee on the Medical Re-examination of Recruits resumed its sittings on November 6th, Colonel Grettton presiding in the absence of Mr. E. Shortt, K.C. Dr. Galloway, Chief Medical Commissioner of National Service, gave evidence as to the scheme under which medical examinations for the army and classifications and gradings have been transferred from the War Office to the Ministry of National Service. The features of the new arrangements have already been published. Dr. Galloway also described the new system of classification of recruits.

Civilian Practitioners' Local War Service.—In answer to Mr. Perkins, Mr. Macpherson said that the employment of civilian medical men willing to work as civilian medical practitioners in the neighbourhood of their homes was one for general officers commanding-in-chief of the various commands. So far as the War Office was concerned, such offers were welcomed.

Hospital Physicians and Army Medical Service.—Mr. Alden inquired whether Mr. Macpherson was aware that when hospital physicians and surgeons were asked to join the Royal Army Medical Corps Territorial Force in 1908 they were given a definite official assurance by the then Director-General of the Army Medical Service that, if they did so, their appointment would entail no duties in time of peace, but a liability in time of invasion or national emergency to perform only clinical duties identical with those they performed in civil life in general hospitals; and whether he would explain why a number of hospital physicians and surgeons who were over military age, and who joined the Royal Army Medical Corps Territorial Force on this understanding in 1908, had been compelled to perform duties other than clinical which were wholly foreign to their previous experience. Mr. Macpherson said the answer to the first part of the question was in the affirmative with the qualification that no promise was made that the clinical duties should be identical with those performed in civil life. He was not aware of any case in which these officers were compelled to do duties other than clinical.

Medical Examination of Recruits.—In reply to Sir Hamar Greenwood, Sir A. C. Geddes said that the Ministry of National Service had taken over that part of the function of the Army Medical Service which is concerned with the medical examination of the physical fitness of recruits and potential recruits. Civilian medical practitioners who had been employed on a recruiting medical board would, however, be eligible for re-employment under National Service.

Soldiers Disabled by Rheumatism and Tuberculosis: After-care Colonies.—Mr. Anderson asked the Pensions Minister whether he was considering how to provide gratuitous treatment on scientific lines for all soldiers and sailors suffering from rheumatism and tuberculosis; and whether he would consider the desirability of making grants, in addition to their pension, so that they might reside in health institutions under the care of specialists until every effort towards cure had been made. Sir A. Griffith-Boscawen said that under the instructions of the Ministry Local War Pensions Committees had full power to arrange with any existing institution for the treatment of rheumatism, and those powers had been widely used. Should it be found that existing accommodation was insufficient, the Minister was ready to give assistance towards meeting the need. Treatment for tuberculosis was provided by the National Insurance Commissioners in conjunction with the local authorities. In order that the disabled man might obtain the fullest advantage of these arrangements, grants had been made to assist the funds of Insurance Committees, and, in addition, the Minister had undertaken to provide the whole cost of treatment for advanced cases. Moreover, the Ministry were at present considering the question of providing after-care colonies where treatment and training might be given in cases of this disease in its early stage. Every means possible would be adopted to bring about an effective cure wherever cure was possible.

Military Hospitals for Venereal Disease.—In reply to a question by Mr. Arnold Ward, which contained a suggestion that objection had been raised locally to the establishment of military hospitals for venereal disease in or near urban districts in the Eastern Command, Mr. Macpherson said that the concentration of such patients in special hospitals assured the utmost advantage to health and the speedy return of the men to duty. There had been local opposition not only in the Eastern Command, and the feeling was so strong against the use of buildings that it had become necessary to utilize hutments.

Criminal Law Amendment Bill.—Mr. Ramsay MacDonald asked the Home Secretary whether, in view of the state of public business and the unlikelihood of any progress being made with the Criminal Law Amendment Bill this session, he would consider whether he could use his powers under the Defence of the Realm Act, or otherwise, to provide safeguards against the worst dangers by which soldiers were beset, and the grossest carelessness in communicating disease. Sir G. Cave replied he regretted the opposition to the Criminal Law Amendment Bill, the passage of which would in his opinion reduce the evil referred to in the question. It was for the Army Council to consider whether anything could be effected by a regulation under the Defence of the Realm Act.

THE WAR.

UNITED STATES ARMY MEDICAL SERVICE.

TRANSPORT AND TREATMENT OF WOUNDED.

In continuation of the note on this subject published last week we give the following further particulars drawn from the articles published by Colonel Reno in the *New York Medical Journal*. In the organization of the transport of wounded two zones are recognized—the zone of the advance (or of combat) and the zone of the line of communications, leading to the base. As has been stated, a regiment of infantry has four medical officers, and other divisional units have a proportional number. The regimental medical officers establish a regimental aid station. The next unit is the ambulance company, of which there are four to a division under the collective command of a major; each ambulance company appears to have four medical officers. Its transport may be mechanical or horse. When the division is in action each ambulance company provides a dressing station, to which men of the company transport the wounded from the regimental aid station, usually by hand litter or wheeled litter, but by ambulance if possible, or by any other means of transport. Ambulances ply between the ambulance company dressing station and the field hospital.

The field hospitals, of which there are four to a division, are tented, each providing 216 beds in six "ward tents," 16 ft. by 50 ft.; there are also four "hospital tents," 14 ft. by 16 ft., housing the dispensary, office, operating-room, and stores respectively; a kitchen is placed under a tent fly. When, however, buildings are available, the tentage is not pitched. Such surgical operations are done here as are needed to fit the men for transportation; they are performed under the strictest antiseptic or aseptic precautions, and every effort is made to dress wounds so that they will not require redressing for some time. A field hospital is relieved of its wounded as rapidly as possible. When the number of wounded is great and transport facilities to the rear are bad, or when there are non-transportable wounded, a section or the whole of a field hospital, or even several field hospitals are immobilized, and their administration is then taken over by the line of communications, which provides the division with duplicate equipment. Two of the field hospital companies with a division have motor transport—eleven trucks, each of a capacity of a ton and a half, and two motor cycles or a touring car. Each has six medical officers—a major and five captains or lieutenants of the Medical Corps or Medical Officers' Reserve Corps—three non-commissioned officers, two cooks, one mechanic, and sixty-eight privates, all belonging to the medical department. The transport of an animal-drawn field hospital company consists of seven wagons, with a capacity of one and a half tons each, four draft mules for each wagon and two extra, and twenty-two riding horses. It has the same number of medical officers and non-commissioned officers, but it has a horse-shoer, a saddler, and a farrier in place of three of the privates in the motor hospital.

The next link is the evacuation ambulance company—a transport column which passes the wounded from field hospitals to the evacuation hospital, described as the first hospital in the zone of the line of communications; apparently it corresponds very nearly to the British casualty clearing station.

SCHOOLS OF INSTRUCTION FOR ARMY MEDICAL OFFICERS IN AMERICA.

Training camps for newly appointed medical reserve officers, established by the Surgeon-General of the United States Army, were in full swing last July. There are three main training camps, each with a capacity of a thousand student medical officers, at Fort Riley, Kansas, at Fort Benjamin Harrison, Indiana, and at Fort Oglethorpe, Georgia. At each camp there are four ambulance companies, four field hospitals, one evacuation hospital, and six regimental detachments. There is also a training camp for coloured medical officers at Des Moines, Iowa, where ten regimental detachments of coloured men are to be organized. The course at each camp occupies about eight hours a day for three months. During the first month the instruction

is in the work of the enlisted men of the medical department, so as to fit student officers for duty as instructors; the second month is given to the duties of medical officers proper; and the third to work in the field, such as the conduct of ambulance companies, field hospitals, and so on. The student officers are organized in provisional companies of 150 men each, with officers and non-commissioned officers appointed from their number. At each camp there are ten regular medical officers as instructors and in charge of the administration. The three main training camps have a capacity of producing about 12,000 trained military medical officers annually. Upon completion of the course the more experienced physicians and surgeons are relieved and assigned to other duties. Selected officers are sent for special training to the Rockefeller Institute for instruction in laboratory work, or to other centres, including Cornell Medical College, New York, for instruction in x-ray work.

THE USAACS.

On the outbreak of war steps were taken to enlarge the United States Army Ambulance Corps. We gather from an article published recently in the *New York Medical Journal* that the volunteer American Ambulance Service, established by the Friends of France on the French front, has been taken over, but the main enlargement has been by way of enlistment in America. A training camp has been established at Allentown, Pennsylvania, where there is ample room, a good water supply, and extensive buildings. Dr. Arthur Yale of Philadelphia, now a major in the service, was able to supply 700 men from an organization of Church clubs he had established in Philadelphia, and the Intercollegiate Bureau at Washington undertook to supply the number of men needed to make up the total of 4,100 at first contemplated. The commanding officer of the camp is Colonel E. E. Persons, and the sanitary officer Major Richard Slee, both of the regular army. Each unit comprises three sergeants, a corporal, two mechanics, two cooks, and thirty-seven privates, with a lieutenant in command. Four units constitute a company, under the command of a captain, and five companies a battalion. Each unit has twenty-four automobile ambulances, an officer's car, three trucks, and kitchen trailers.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Wounded.

Surgeon R. G. Morgan, R.N.

Surgeon T. N. McB. Ross, M.C., R.N.

ARMY.

Killed in Action.

LIEUT.-COLONEL C. R. A. PYE, D.S.O., M.B.

Lieut.-Colonel Cecil Robert Arthur Pye, D.S.O., M.B., Ch.B.Syd., was killed on October 4th whilst commanding the 19th Battalion Australian Infantry. He was born at Windsor, N.S.W., on July 7th, 1890, and entered the Sydney University Medical School, and graduated M.B., Ch.B.Syd., after which he studied in England. On his return to Australia the war had commenced, and he at once volunteered, preferring to remain with the infantry, in which he had previously served, and in which he had been promoted captain in 1913. Lieut.-Colonel Pye served at Anzac with the 17th Battalion Australian Infantry. He was a skilful medical man, a gallant soldier, and a most competent commanding officer, and had earned the highest praise from the A.I.F. commander. On May 11th he was awarded the D.S.O. for conspicuous gallantry and initiative when in charge of the whole of the front line held by his battalion. He organized a successful attack, and exhibited great energy and determination when meeting a counter-attack made by the enemy. He set a splendid example to the men under him.

CAPTAIN G. S. ELLIOTT, A.A.M.C.

Captain George Stephenson Elliott, A.A.M.C., whose death in action, on September 26th, at the age of 32, was announced in our issue of October 27th, was the youngest son of the late Mr. Thomas Elliott, of Ballarat, Victoria, and a brother of Brigadier-General H. E. Elliott, D.S.O., C.M.G., commanding the 15th Infantry Brigade. He was

educated at Ballarat College and Melbourne University, graduating M.B., B.S., in March, 1916. For some months he was medical officer at No. 5 Base Hospital, Melbourne. He arrived in England in September, 1916, and soon joined the 56th Battalion as its medical officer, remaining with it until his death. He had been recommended for a decoration for his previous fine work at Bullecourt, and was nominated for the New Year's Honour List. He was very well known in Victoria as an athlete and a playing member of the University League football team. He leaves a widow and infant daughter.

CAPTAIN J. B. RANDALL, R.A.M.C.

Captain John Beaufoy Randall was killed in action in France on October 31st, aged 28. He was the younger son of Mr. Wyndham Randall, surgeon of Bridgend, Glam., and was educated at Bridgend County School and St. Bartholomew's Hospital. He graduated B.Sc.Lond., with honours in physiology, in 1911, and M.B., B.S.Lond., with honours and distinction in medicine, in 1914. He subsequently served for one year as house-physician to St. George's Hospital, joined the R.A.M.C. as temporary lieutenant in January, 1916, and soon proceeded to France. He was promoted to captain after a year's service, and was home on leave in September last.

CAPTAIN J. STRUTHERS, S.A.M.C.

The annual obituary of Edinburgh University, dated October 15th, gives the name of Captain John Struthers, South African Medical Corps, as killed in action, without date. He graduated M.B. and C.M.Edin. in 1894, and before the war was in practice at Neora, Colimvaba, Tembuland, South Africa.

Died of Wounds.

CAPTAIN W. G. MCCONNELL, R.A.M.C.

Captain William Gardiner McConnell, R.A.M.C., was reported as having died of wounds, in the casualty list published on November 2nd, after his name had appeared in the list of wounded a fortnight before. After taking the L.R.C.S.I. and L.R.C.P.I. in 1915, he joined the R.A.M.C. as a temporary lieutenant, and was promoted to captain after a year's service.

CAPTAIN W. MORRISON, M.C., R.A.M.C.

Captain William Morrison, M.C., R.A.M.C., died in hospital of wounds and gas poisoning on October 23rd. He was the younger son of the late Rev. W. Morrison of Mulben, Keith, and was educated at Milne's Institution, Fochabers, and at Edinburgh University, where he graduated M.B. and Ch.B. in 1909, after which he joined the British East Africa Medical Service. He took a temporary commission as lieutenant in the R.A.M.C. on March 17th, 1915, and was promoted to captain after a year's service, receiving the Military Cross on November 25th, 1916. He had served at the front for about two years past, except for a few months in the winter of 1916-17, when he was recovering from shell shock.

CAPTAIN A. Z. PHILIPS, R.A.M.C.

Captain Abraham Zadok Philips, R.A.M.C., died on October 24th of the effects of gas poisoning on the previous day, aged 36. He was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1910, and M.D., with commendation, in 1913, also taking the London D.P.H. in 1914 and the F.R.C.S.Edin. in 1915. He afterwards filled the posts of house-physician at the Royal Southern Hospital, Liverpool, and of house-physician and house-surgeon at the Liverpool Infirmary for Children. After serving, in the first year of the war, as surgeon to the Florence Fienes hospital at Dunkirk, he took a temporary commission as lieutenant in the R.A.M.C. in July, 1915, and was promoted to captain on completion of a year's service.

CAPTAIN D. J. S. STEPHEN, M.C., R.A.M.C.

Captain David James Shires Stephen, M.C., R.A.M.C., died of wounds and of gas poisoning on October 23rd. He was educated at Aberdeen University, where he graduated M.B. and Ch.B. in 1910 and M.D. in 1912, afterwards filling the posts of senior house-surgeon of Lincoln County Hospital and of assistant medical officer of the Lawn Asylum, at Lincoln. He joined the R.A.M.C. as a temporary

lieutenant on October 10th, 1914, and was promoted to captain after a year's service. He gained the Military Cross on July 24th, 1915.

Died on Service.

MAJOR H. E. DALBY, R.A.M.C.(S.R.).

In the obituary notice (published in the *BRITISH MEDICAL JOURNAL* of October 27th) of Major H. E. Dalby, R.A.M.C.(S.R.), who died at Basra on October 14th after an operation for appendicitis and peritonitis, it should have been stated that he served in the R.A.M.C. from 1899 to 1905, when he retired, and joined the Special Reserve, settling in practice at St. Mary Church, Torquay. He rejoined at the outbreak of the war, and served with the 8th Field Ambulance in the retreat from Mons, after which he was invalided home. On recovery he was appointed Principal Medical Officer at Witley Camp, Surrey. In September, 1915, he was put in medical command of the hospital ship *Braemar Castle*, and in May, 1916, transferred to the *Assaye*.

LIEUTENANT W. C. McMILLAN, I.S.M.D.

Lieutenant William Calderwood McMillan, Senior Assistant Surgeon, I.S.M.D., died on active service of pneumonia on October 24th, aged 45. He was born on April 18th, 1872, educated at the Calcutta Medical College, and entered the Indian Subordinate Medical Department on February 21st, 1893, becoming first-class assistant surgeon on February 21st, 1912, and getting his commission during the war. He had been successful in the study of Indian languages, having passed the High Proficiency test in Urdu, and the Higher Standard in Persian, Pushtu, and Panjabi. Before going on service he was stationed in Calcutta.

LIEUTENANT AND QUARTERMASTER H. UNDERWOOD, R.A.M.C.

Lieutenant and Quartermaster Harry Underwood, R.A.M.C., died of dysentery on service in Egypt on October 18th. After serving in the ranks, he attained warrant rank as sergeant-major on October 12th, 1914, and had since received a commission.

SUB-ASSISTANT SURGEON GAURI SHANKAR, I.S.M.D.

First class Senior Sub-Assistant Surgeon Gauri Shankar, I.S.M.D., was reported as having died on service in the casualty list published on November 1st. He was born on May 12th, 1868, entered the I.S.M.D. on March 25th, 1889, and attained his late grade, ranking as subadar, on August 16th, 1914. He had gained the Indian Order of Merit during the war. Before going on service he was serving in the station hospital at Jullundar.

Wounded.

Major W. R. Craig, Australian A.M.C.
Major T. J. Frizell, Australian A.M.C.
Major F. M. Furber, Australian A.M.C.
Captain J. Arthur, R.A.M.C.(T.F.).
Captain C. H. Brennan, R.A.M.C.(S.R.).
Captain J. E. Cable, R.A.M.C. (temporary).
Captain S. R. Glead, R.A.M.C. (temporary).
Captain W. G. Gondie, R.A.M.C. (temporary).
Captain H. B. Graham, R.A.M.C. (temporary).
Captain E. B. Leech, R.A.M.C. (temporary).
Captain R. Mackinnon, R.A.M.C.(S.R.).
Captain R. D. Nasmyth, R.A.M.C. (temporary).
Captain W. J. Nisbet, R.A.M.C. (temporary).
Captain P. S. Parkinson, Australian A.M.C.
Captain D. H. Russell, M.C., R.A.M.C. (temporary).
Captain R. W. Ryan, R.A.M.C. (temporary).
Captain W. Steadman, R.A.M.C. (temporary).
Captain H. C. Watson, R.A.M.C. (temporary).
Lieutenant A. P. Draper, R.A.M.C. (temporary).
Lieutenant E. B. Leech, R.A.M.C. (temporary).
Lieutenant J. N. Morris, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Anderson-Berry, David Douglas Anderson, Captain Royal Scots, the Lothian Regiment, only son of Dr. Anderson-Berry, of Highgate, killed September 26th, aged 27. His first commission was dated May 12th, 1915.

Burnside, Eustace Bruce, Captain the Buffs (East Kent Regiment), only son of Colonel E. A. Burnside, A.D.M.S., Ripon, killed October 12th, aged 22. He was educated at Eton and at Balliol College, Oxford, got a commission in the Buffs at the outbreak of the war, and became lieutenant on December 27th, 1914.

Cunningham, S. Gordon, Second Lieutenant Royal Field Artillery, youngest son of Dr. Cunningham, of Bellevue, Cambellton, killed October 22nd, aged 25.

Edwards, D. W., M.C., Captain Army Service Corps, attached Royal Flying Corps, younger son of Captain C. R. Edwards, R.A.M.C., reported missing April 6th, 1917, now presumed killed on that date.

Holton, Francis Keatley, Lieutenant Middlesex Regiment, only son of Dr. F. W. P. Holton, killed October 27th, aged 20. He was educated at St. Edward's School, Oxford, and destined for the Church, but entered the army through Sandhurst. He got his commission in January, 1916, and went to the front in August, 1916.

Inch, Robert Stuart Mark, M.C., Lieutenant Norfolk Regiment, younger son of Dr. Inch, of Gorebridge, Midlothian, killed October 22nd. He was educated at George Watson's College, Edinburgh, and adopted the profession of accountant, obtaining his commission through Edinburgh University O.T.C. He received the Military Cross twelve months ago, and was wounded in 1916.

Waller, Thomas Henry Whalley, Lieutenant Gloucestershire Regiment, killed in action on October 22nd, aged 21, was the only son of Dr. A. W. Waller, of Stroud, Glos. He was educated at St. Peter's School, Weston-super-Mare, and Malvern College, and had been registered as a medical student. Acting as captain he had led his company "over the top" and gone straight through to the objective, successfully holding the ground gained all day until he was shot by a sniper's bullet and instantly killed.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

FOOD ADMINISTRATION IN MILITARY HOSPITALS.

We have received a copy of a pamphlet on the administration, conservation, and accounting of hospital food supplies,* which has been issued by authority for use in Canadian military hospitals in England. Here are brought together in a handy form the many regulations bearing upon commissariat, both those that are old-established and those contained in recent Army Council instructions or Canadian routine orders. All those who are directly concerned in the diet of invalid Canadian soldiers, from the medical officers in charge of wards and nursing sisters up to the officer commanding, will find in this summary a practical guide to their duties in respect of food and feeding. The pamphlet is interleaved so that any future orders and regulations may be inserted, if necessary. The instructions with regard to the ordering of diets and extras should resolve some of the difficulties encountered by newly appointed medical officers unfamiliar with the mysteries of army diet sheets and summaries; while the section on the conservation and disposal of cook-house refuse should prove of much assistance to administrative officers. It is evident that economy in dealing with hospital kitchen refuse has been reduced to a system which secures the least possible waste with the largest cash return. This standardized method of sorting and selling by-products and disbursing the proceeds shows what can be done when the "dripping fund" of a military hospital is run on business lines. Although the pamphlet is intended only for Canadian hospitals there are many other administrative officers who would probably find it helpful, and we should not be surprised if a compilation on similar lines were soon issued for British military hospitals.

MENTIONED IN DISPATCH.

A dispatch from General Sir Charles Monro, Commander-in-Chief in India, describing military operations on the North-West Frontier, in Persia, and elsewhere, from March 10th, 1916, to March 31st, 1917, was issued as a supplement to the *London Gazette* on October 31st. The following medical officers are included in a list of officers and men brought to notice for gallantry and good services appended to the dispatch: Major C. E. W. S. Fawcett, R.A.M.C.; Captains J. B. Hanafin and M. A. Rahman, I.M.S.; Lieutenant B. S. Dhondy, I.M.S.; Assistant Surgeon J. W. Marshall, I.S.M.D.; First Class Sub-assistant Mirza Mohammed Beg Khan Bahadur, I.S.M.D.; and Third Class Sub-assistant Surgeons Silaram Vishnu Sathe, Sorosbi Ranjan Sen, and Karam Bayeram, I.S.M.D.

HONOURS.

The Emperor of Japan has conferred the Order of the Sacred Treasure (First Class) upon Surgeon-General Sir Arthur W. May, K.C.B., F.R.C.S., K.H.P., late Director-General Medical Department, R.N., for distinguished services rendered during the war.

The Distinguished Service Cross has been awarded to Surgeon-Probationer A. C. Fowler, R.N.V.R., for services in action with enemy submarines.

* *Hospital Food Supplies: Administration, Conservation, and Accounting for Use by Canadian Military Hospitals in England.* Issued by the Director of Medical Services Canadians, London.

Captain (acting Major) K. B. Williamson of the Royal Garrison Artillery, formerly a medical student of Edinburgh University, has been awarded the Military Cross.

The President of the French Republic has conferred the Croix de Guerre upon the following medical officers of the Royal Navy: Staff Surgeon Walter T. Haydon and Surgeons Horace E. R. Stephen, M.B., Ronald G. Lyster, and Horace P. Margetts.

Wales.

COLONIES FOR DISCHARGED TUBERCULOUS SOLDIERS IN WALES.

AN interesting announcement was made at the annual meeting of the Council of the Welsh National Memorial held last week at Llandrindod Wells. Major David Davies, M.P., to whom the movement owes its inception and much of its success, stated, as the result of an interview with the Pensions Minister with reference to the establishment of colonies for discharged tuberculous soldiers from Wales whose return to their pre-war occupations might be injurious to the public health, that the Ministry hoped shortly to be in a position to equip sanatoriums with means for training and for giving instruction in various trades, and that colonies would be provided where such men, after undergoing treatment, might continue their training and be enabled to earn their living. The Council was informed that, if the Pensions Minister's scheme was carried out, Major David Davies was prepared to give, free of cost, two valuable properties for the establishment of such colonies. It is understood that negotiations have already been entered into for realizing the project. At the same meeting the resignation of Dr. Marcus Paterson, who has acted as medical director of the National Memorial Association since its formation, was received with the greatest regret, and high appreciation was expressed of the services which he had rendered. It is understood that the vacancy will not be filled up at present, but that temporary arrangements will be made to carry on Dr. Paterson's work during the continuance of the war.

CARDIFF HOSPITAL.

Colonel Bruce-Vaughan, who has rendered such excellent service to the King Edward VII Hospital at Cardiff, in conjunction with other gentlemen, is putting forward a strong appeal for further funds in order to place the hospital on a sound financial basis. It is stated that additional beds to the number of 180 are urgently required in order to provide to some extent for a waiting list of (at present) a thousand prospective patients. Colonel Bruce-Vaughan, as Chairman of the House Committee, appeals (1) for £8,000 to wipe off the overdraft which it is estimated will stand to the debit of the current account at the end of the year, and (2) for an additional income of £15,000, which will be necessary before the new wards now being built can be opened. In addition to this a large amount is required for furnishing and to meet capital expenditure. The suggestion is that the demand should be met, at least in part, on the basis of weekly subscriptions by wage-earners supplemented by proportional subscriptions from the employers of labour. It is pointed out that in Newcastle last year the workmen's contribution towards a similar object was little short of £30,000, and it is held that there should not be any difficulty in obtaining even a larger sum in Glamorganshire.

Scotland.

THE Privy Council has decided to withhold its assent from the ordinance promoted by the four university courts regarding the preliminary examination until a conference with the Scottish Education Department has taken place.

Miss Agnes M'Alpin, founder of the Glasgow Training Home for Nurses (now the M'Alpin Nursing Home) died on November 3rd at the age of 92. She was pioneer of the movement to train nurses, more especially for nursing in private families. She started on a small scale with the help of her sister, who survives her, but had the gratification of being able to attend the opening in 1908 of the new home, where a tablet commemorates her work.

NATIONAL SERVICE MEDICAL ADVISORY BOARD.

The Minister of National Service has appointed the following to be an Advisory Medical Board for Scotland to advise him on questions relating to the examination of men of military age by the National Service Medical Boards. The Secretary for Scotland has appointed the same gentlemen to advise him on questions relating to the examination of such men by the Medical Assessors who are to be appointed by him:

Sir Donald MacAlister, K.C.B., M.D.
R. C. Buist, Esq., M.D.
J. R. Drever, Esq., M.B., Ch.B.
John Gordon, Esq., M.D.
Professor Harvey Littlejohn, M.B., F.R.C.S.E.
Professor T. E. Monro, M.D., F.R.F.P.S.G.
John Playfair, Esq., M.D., F.R.C.P.E.

TUBED FEEDING-BOTTLES.

We are glad to learn that the Central Midwives Board for Scotland has made a formal representation to the Privy Council, urging that the manufacture, importation, and sale of long tube feeding-bottles should be made illegal. After a short preamble on the infantile death-rate in Scotland, the board draws attention to one item in the causes of infant mortality which it believes to be easily susceptible of amelioration—namely, infantile diarrhoea and diseases of the digestive system. Each year the infant death-rate reaches its highest point in the third quarter—July, August, and September. The excess at this season is mainly attributable to fermentative changes in milk, which are fostered by the use of long tube feeding-bottles. These abominations are universally condemned by medical authorities, but are still very popular with poor mothers. Although theoretically cleansible, they always contain an inner coating of coagulated milk, which, especially in warm weather, teems with fermentative micro-organisms, while their use encourages the swallowing of air. Moreover, the child, with the bottle snugly beside it in the cot, is tempted to suck whenever it chooses, and is in consequence often overfed, with the usual train of digestive disorders. Thus chronic fermentation of the food and chronic overfeeding go on side by side so long as these filthy bottles are allowed. In 1910 France, and in 1912 Germany, passed laws prohibiting the tubed feeding-bottle, and it is high time that we fell into line with our friends and our enemies. The Central Midwives Board for Scotland suggests that a single clause bill would meet the requirements of the case. We are glad to give our warm support to this proposal, which need not wait upon the heels of a Ministry of Health but should be enacted at once.

Ireland.

DR. JOHN LUMSDEN, Director-in-Chief of the Joint V.A.D. in Ireland, was entertained to dinner at the Gresham Hotel, Dublin, on November 3rd, by the officers of the Ambulance and Nursing Divisions of the St. John Ambulance Brigade on the eve of his departure for France.

The Ballina Board of Guardians at their last meeting granted to their five dispensary medical officers increases of salary of £20 a year each, with triennial increments of £7 10s. until a maximum of £200 per year is reached.

Dr. Fitzgerald of Newtownbutler and Dr. Mance of Burnbrae, Lisburn, who have both recently recovered from serious illness, have been presented by their friends and patients with illuminated addresses accompanied by valuable gifts.

TUBERCULOSIS IN BELFAST.

In his report for the past three years, presented to the Belfast Municipal Committee of Management on hospitals and dispensaries, Dr. Trimble, chief tuberculosis officer, reviews the history of the scheme of the corporation for dealing with tuberculosis. It has been described by the Local Government Board for Ireland as the most comprehensive scheme in Ireland and one of the most complete in the United Kingdom, providing as it does institutional, dispensary, and domiciliary treatment, not only for all insured and exempt persons, but also for all residents in the city suffering from tuberculosis. The total number of persons examined during the period under review was

7,365; of these, 82.6 per cent. were tuberculous, and 7.6 per cent. suspects; the remaining 9.8 per cent. were not tuberculous. Among the tuberculous the disease was pulmonary in 82 per cent. The greatest incidence of the disease was from 15 to 20 years of age. In Belfast and Ireland generally females suffer more; in Great Britain the reverse holds. The hardships associated with poor economic conditions tell more heavily on the female, and with better conditions of living the high incidence on the female may be expected to change. The total cost of the scheme for the year ending March 31st was £30,681. Dr. Trimble, in discussing the advantages of the scheme, points out that though statistics do not show any marked falling off, the educative effect is good.

TREATMENT OF VENEREAL DISEASE.

The decision of the Government to extend to Ireland the measures for combating venereal diseases that have already been adopted and put into operation in Great Britain will entail an important reorganization of the various sanitary authorities in Ireland. Regulations made by the Local Government Board under Section 148 of the Public Health (Ireland) Act, 1878, respecting provision to be made by the sanitary authority for the diagnosis, treatment, and prevention of venereal diseases have been issued to the county boroughs, county councils, governing bodies and committees of management of hospitals and infirmaries, and to boards of guardians; all these bodies will be concerned in the organization and execution of the necessary schemes. In connexion with all approved measures the Local Government Board for Ireland will repay 25 per cent. of the expenditure incurred under the regulations, and as the Royal Commission on Venereal Diseases expressed the opinion that "the conditions now existing, and those which must follow on the conclusion of the war, imperatively require that action should be taken without delay," sanitary authorities are requested to act promptly. The Order empowers the sanitary authority to make arrangements (a) for the treatment at and in hospitals and other institutions of persons suffering from venereal disease; (b) for placing at the disposal of medical practitioners such skilled assistance in the treatment of venereal disease as may be required; and (c) for supplying medical practitioners with salvarsan, or its substitutes for the treatment and prevention of venereal disease. It is understood that the existing hospitals and infirmaries will meet the demands for this treatment. Sanitary authorities are expected to prepare and submit for approval a scheme. Hospitals with which arrangements are made may, in many instances, be prepared to undertake further arrangements for enabling medical practitioners to obtain reports on blood and other materials submitted for examination, and for supplying practitioners with the necessary drugs. Such arrangements might be made in other cases with the authorities of university laboratories and reliable pharmacists. All information obtained in regard to any person treated must be regarded as confidential. The widest publicity is to be given to the fact that facilities for treatment are available for any person affected with the disease, and provision is being made for instructional lectures and for the publication of information on questions relating to the disease as may be thought necessary or desirable.

Canada.

THE MILITARY SERVICE ACT.

The total enlistment in Canada up to July 15th, 1917, was 426,622; the population of males in Canada between the ages of 18 and 45, according to the census of 1911, was 1,720,070. Of the various provinces, Ontario has contributed 40,133 more than its proportionate share, while Quebec is 50,176 behind its share. The Maritime Provinces have failed by 5,554 to send their proportionate quota, whereas the Western Provinces have sent more than their share—Manitoba and Saskatchewan by 7,943, Alberta by 5,448, and British Columbia by 2,206. The first class of recruits under the Act will be called up at the beginning of October, and medical boards are being established throughout the country and arrangements have been made for the immediate examination of men

who present themselves so as to avoid congestion and consequent delay when the Act goes into force. Physicians of military age will be divided into three classes according to their physical fitness—Class A, who will go overseas; Class B, who will be posted for duty in England or at one of the Canadian camps; and Class C, who will serve on the staffs of hospitals in this country.

THE CONTROL OF FOOD.

A recent Order in Council restricts the use of beef and bacon, which must not be served in public eating places on Tuesdays or Fridays or at more than one meal a day. In order to conserve the supply of wheat, substitutes for white bread must be placed on the table whenever the latter is served. The use of canned vegetables is discouraged while fresh vegetables are obtainable. The use of wheat is forbidden in the distillation or manufacture of alcohol, unless such alcohol is to be used for commercial or munition purposes, and any person who desires to use wheat for such purpose must first obtain a licence to do so from the Food Controller.

THE RETURNED TUBERCULOUS SOLDIER.

Some interesting points were brought up at a conference in Ottawa of medical officers in charge of sanatoriums under the direction of the Military Hospitals Commission. All members of the Expeditionary Force, whether they have been overseas or not, who are suffering from tuberculosis, are admitted to these institutions. The discussions centred largely round questions of discipline. It has been found inadvisable to send officers and men to the same institution for treatment, and it was recommended that in future they should be treated in separate sanatoriums. It was also thought advisable that a separate institution should be established for chronic cases, which filled beds in the sanatoriums that should be used for men with a chance of recovery. Incurrigibles, it was thought, should be sent to a detention sanatorium, where discipline could be rigidly enforced.

The opinion was expressed that men on their return to Canada should be allowed to visit their families before entering a sanatorium, as otherwise they might be discontented and perhaps refuse treatment, thereby becoming a menace to the community. Cases had occurred in which men had refused to be treated, and had signed forms releasing the Government of all responsibility towards them, but later had returned and asked to be admitted into the sanatorium. Such men, it was thought, should be treated leniently and allowed to retest, thus receiving pay and allowances. At holiday times, such as Christmas, patients should not be allowed to go home, as experience had shown that at such times they would eat and drink too much and probably suffer a relapse on their return to the sanatorium; leave might, however, be given a little before the festive season, and if the reason for this were carefully explained to the men there would be no difficulty in most cases. It was unanimously resolved that it ought to be made a penal offence for any one to give intoxicating drink to a tuberculous soldier.

It has been the custom of the Medical Board at Quebec to recommend a man for six months' treatment. This has been found to be a mistake, as, at the end of the time stated, the man expects to be cured, and it has been difficult sometimes to keep him in the sanatorium longer than that. It was considered that no definite time should be mentioned. Emphasis was laid upon the great value of occupation both as an aid to discipline and a promoter of health. It took the minds of the patients off their own troubles and even bed cases could do fancy work. The interest they would take in their own work and in getting up little exhibitions was notable.

It was thought that no doctor should be expected to treat more than fifty men, and that an additional medical officer should be provided for every additional forty patients or less. A medical man should not be burdened with any duties beyond the medical treatment of his patients.

SOME time ago it was announced that the medical department of Columbia University, New York, had opened its doors to women students. Eight have entered for the current session. Harvard, which also proposed to admit women to its medical school, has, it is stated, withdrawn its offer, only one woman who was regarded as a desirable student having presented herself.

Correspondence.

BACTERIOPHORIA (CARRIAGE OF BACTERIA BY "CARRIERS").

SIR,—There are diseases the bacteria of which may be present in persons who do not themselves exhibit the symptoms of any disease; such a person may have recovered from the disease of which he has the bacteria or may never have shown any symptom of it. Yet such a person is or may be capable of conveying the bacteria present in himself to other persons, who may thus become infected with, and suffer from, the disease producible by the bacteria conveyed. These persons are commonly called *carriers*. The word *carrier*, unaccompanied by any reference to the thing carried, is insignificant; *germ-carrier* or *germifer* may be suggested in substitution; but for reasons which in the pages of this JOURNAL I need not set forth, neither can be regarded as scientific. I propose that the conveying persons above described should be called *bacteriophorous*. If this name be accepted, the state will be called *bacteriophoria* and the conditions *bacteriophoric*. It will be convenient to explain the manner in which the names have been arrived at.

The use of *phoros* in compounds, to signify bearing or carrying, is well established by such words as *δορυφόρος* (spear bearing or carrying) and *ὄπλοφόρος* (bearing, carrying, or wearing arms), most of which are used also as substantives. By uniting it with *βακτήριον* (bacterium, regarded as the singular of bacteria) we get the word *βακτηριοφόρος*. And as the Greek termination *os*, represented in Latin by *us*, becomes in English *ous* (*ἄμορφος*, for example, becoming *amorphous*, and the Latin *garrulus* becoming *garrulous*), the English equivalent must be *bacteriophorous*. Then, from the coined word *βακτηριοφόρος* can be formed, to describe the state, process, or involuntary act of carrying bacteria, the word *βακτηριοφωρία* (*bacteriophoria*), by analogy to the formation of such words as *θυρσοφωρία* (a carrying of the thyrsus or Bacchic wand, from *θυρσοφόρος*). And, again, by analogy to the formation of such words as *φιλικός* (of or for a friend, belonging or suitable to friendship, from *φίλος*, *φιλία*), can be formed, to describe the conditions or circumstances, the word *βακτηριοφορικός* (*bacteriophoric*).

I may add that *bacteriophorous* persons can be called the *bacteriophorous*, just as *scrofulous* persons are called the *scrofulous*, or perhaps the substantive, *bacteriophore*, might be admitted.

Finally, I may be allowed to say that I have written this letter merely on account of the objections which I entertain to the use of the word "carriers," which, besides being strictly meaningless, is in truth little better than slang, and in the hope that it may become disused.—I am, etc.,

October 29th.

M. G. D.

THE REMUNERATION OF RURAL PRACTITIONERS.

SIR,—Recently some letters have appeared with regard to the remuneration of rural practitioners. A big change has taken place in my particular district, the population of which has decreased about 500 in the last ten years, and during that period the number of doctors has fallen from twelve to six, and of these six, two have gone to the war. The district is purely agricultural, with the exception of one small area. There must be some reason for these remarkable figures, and I think that is to be found in the finances of country practice.

The advertisements in the JOURNAL of practices for sale seem to show that the average receipts of purely agricultural practices are quite half those of the town. Yet the expenses are certainly more in the country, as a motor car or other means of conveyance is a necessity and not a convenience as it is in a town. Under the National Insurance Act town and country patients are paid for at the same rate, and, although there is less sickness in the country, there is more work and more highly-skilled work. It is quite probable some of the town practitioners will be inclined to dispute these points, but I have gone into the first with my town friends, and I find that although the number of consultations are more in the town, the visits are much more in the country. The

reason for this is obvious when one considers the number of chronic cases in which a walk along a well-paved foot-path of a quarter of a mile is possible, but in which two or three miles of bad, possibly hilly, roads would be out of the question. Moreover, many patients whose health has hopelessly broken down leave the towns and retire to the country, and require medical attendance for the rest of their lives. This applies with especial force to consumptives. As to the second point, that more skilled work is demanded, the absence of hospitals in the country means that nearly every case which in the towns would go to the hospitals has to be treated by the local man single-handed, with the possible help of a neighbour. A cottage hospital may lessen the amount of travelling, but does not usually affect the responsibility. "Rus in Urbe," in your issue of October 20th, points out that discharged soldiers and sailors and temporary residents are paid for at the same rate in the town and country, and mentions the observation of a "leader" of our profession that a good many attendances at even a small fee will amount to a considerable sum. I am attending now a discharged soldier living three miles away. It costs me at least 5d. a mile to run my car in this hilly country; I shall be paid 2s. 6d. each visit, or to speak more accurately some indefinite sum less than 2s. 6d., and I cannot see how a good many attendances will leave me better off. This particular case was a private patient before the war and always paid a reasonable fee.

I am well aware that country practice has its charm; the fact that we are seldom able to throw the responsibility of our serious cases upon the broad shoulders of a consultant or hospital is in itself a strong incentive to the constant study of our profession. But we ought to be paid a living wage for the work we do for the Government. It is our private patients that enable us to live, and it is only because we are afraid of losing these that we take insurance work. Even with our private practice, something more is often required. My practice, as a country practice, would be called a good one, but with every economy I could not live without my private income.—I am, etc.,

October 31st.

A COUNTRY DOCTOR.

THE CURE OF INGUINAL HERNIA.

SIR,—In his paper in the BRITISH MEDICAL JOURNAL of October 27th Lieut.-Colonel A. J. Hull, F.R.C.S., has described a form of herniotomy which he apparently considers quite original, but as a matter of fact it resembles in all its essential features the procedure which I have performed in a large proportion of my cases during the past fifteen years. As this operation is fully described in my work on operative surgery (p. 205 et seq.) I need not allude to it more fully. Like Lieut.-Colonel Hull, I sometimes operate with local anaesthesia, but as a rule I prefer a general anaesthetic.—I am, etc.,

EDWARD H. TAYLOR, F.R.C.S.I.,

Regius Professor of Surgery, University of Dublin.

Dublin, Oct. 31st.

SCOTTISH NON-PANEL DOCTORS AND A MINISTRY OF HEALTH.

SIR,—There appeared in the BRITISH MEDICAL JOURNAL of November 3rd, p. 602, a report of the annual meeting of the Medical Guild, in which the statement occurred that it is "an organization of non-panel practitioners for the purpose of opposing the National Insurance Act." I shall be obliged if you will allow me to say that this statement is inaccurate. The policy of the Guild is not, and never has been, to oppose the National Insurance Act, but the Medical Benefits Section of that Act as at present administered. The following is the policy of the Guild on this question:

1. To maintain the freedom of the profession in its professional and personal relations with the public.
2. To encourage the public to maintain a corresponding freedom.
3. To oppose the method of administration of the medical benefits under the National Insurance Act in so far as it interferes with such freedom.

These are also incorporated in the policy of the National Medical Union, of which the Guild is a federated body.—I am, etc.,

FREDERICK PORTER,
Hon. Sec. the Medical Guild.

Edinburgh, Nov. 6th.

PANEL DOCTORS' REMUNERATION.

SIR,—In your issue of the JOURNAL for October 27th, under the heading of "Panel doctors' remuneration," it is stated that Sir E. Cornwall said, in reply to a question by Mr. Snowden, M.P.:

In the great majority of cases the final payments for the year 1916 had been made, and in those areas where some balance was outstanding the amount would only be small, as the sums which had been advanced monthly or quarterly during the year would have approximated closely to the total sums which would be found to be due on the final settlement.

This surely does not apply to the Pembrokeshire area, since the panel practitioners only received, for 1916, 5s., instead of 7s.—namely, 1s. 3d. per quarter instead of 1s. 9d. The balance due cannot be considered a small one.—I am, etc.,

CHAS. A. BRIGSTOCKE,

Honorary Secretary Pembrokeshire Local Medical and Panel Committees.

October 31st.

Obituary.

SIR DAVID C. McVAIL,

CONSULTING PHYSICIAN, ROYAL INFIRMARY, GLASGOW.

We regret to announce the death, on November 4th, of Sir D. C. McVail, at his residence in Glasgow. Though in his 73rd year, the war had brought him back to active hospital work, and he was attached to two war hospitals. He rejoiced in being able to do such work, but it was a severe strain upon his strength. He continued to work while suffering from a cold, which was followed by pneumonia, to which cause his death was due.

David Caldwell McVail was born at Kilmarnock in 1845, and received his early education from William Gunnyon, an erudite classical scholar, and afterwards under Donald Ferguson, one of the foremost teachers of Kilmarnock Academy. He began his medical studies by becoming apprenticed to a local druggist. He received his medical education in Glasgow, first at the Andersonian College, and afterwards in the University. He took the diploma of L.R.C.P. Edin. in 1866, and subsequently held the office of house-surgeon to the Alnwick Infirmary down to 1871. In 1876 he graduated M.B. Glasg., and in 1877 was elected Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow. He succeeded Dr. Eben Watson as professor of physiology in the Andersonian College, but in 1880 co-operated with Dr. Knox and Dr. Reid in founding the Western Medical School, in which he held the lectureship in the practice of medicine and was at the same time dispensary physician to the Western Infirmary. At this period he engaged in original research, the results of which were published in a course of lectures on the mechanism of respiration in normal and abnormal conditions, which was honoured by a Faculty honorarium of fifty guineas. In St. Mungo's College, of which in 1889 Dr. McVail was one of the founders, he became professor of clinical medicine, and at that time was appointed physician to the Royal Infirmary, continuing to hold both posts until 1906.

By his accomplishments as a physician he gained a large practice, and by the interest he showed throughout his life in university affairs and in medical reform in many directions he became an acknowledged leader of the profession in Glasgow. He was a member of the Glasgow University Court for nearly a quarter of a century, and took a leading part in its business. Before this he had been largely instrumental in obtaining the Act of 1889, embodying a scheme for university reform which revolutionized the university life of Scotland; it resulted in raising the standard of teaching and in the establishment of several new chairs and many lectureships. He was appointed a Crown representative for Scotland on the General Medical Council in 1892, and when he retired after twenty years' service was succeeded by his brother, Dr. J. C. McVail, vice-chairman of the National Insurance Commissioners in Scotland. Both on the General Council of the University and on the General Medical Council Sir David McVail was a frequent and effective speaker; his influence was due, as he himself said, mainly to the fact that he never took up any subject without having mastered every detail and circumstance bearing upon it. He was no respecter of persons or precedents, but subjected every proposal to the test of common

sense, and the keen critical spirit with which he was so amply endowed.

He received the honour of knighthood in recognition of his public work in 1910. He is survived by Lady McVail, by a son, who is a member of the medical profession, and a daughter.

T. T. WHIPHAM, M.D., F.R.C.P.,

CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL, LONDON.

Dr. THOMAS TILLYER WHIPHAM died on November 3rd at the age of 78, at Hatherleigh, a Devonshire village to which he had retired some years ago. He was the son of Mr. T. H. Whipham of Lincoln's Inn, and was educated at Rugby, and Oriel College, Oxford. He graduated M.B. Oxford in 1866 and proceeded M.D. in 1888. During his whole professional life he was associated with St. George's Hospital, holding in succession the appointments of demonstrator in anatomy, curator of the museum, and lecturer on botany, pathology, and medicine. He was first assistant physician and afterwards physician to the hospital, and on his retirement was appointed consulting physician. He became a member of the Royal College of Physicians in 1866 and a Fellow in 1873; he was censor in 1894 and senior censor in 1901. He had been physician to the Atkinson Morley Convalescent Hospital and examiner in medicine to the University of Oxford and to the Conjoint Board of the Royal Colleges in England. Dr. Whipham was for many years an active worker, especially in the *post-mortem* room, and frequently took an effective part in the proceedings of the Pathological Society, the fortnightly meetings of which used to be so largely attended. After his retirement he was seldom seen in London, and devoted himself to country pursuits. He was a J.P. for the county of Devon.

THE death occurred at Eton, on November 1st, of Lieut.-Colonel WILLIAM AUGUSTINE ELLISON, Surgeon Apothecary to His Majesty's Household at Windsor Castle, and Consulting Physician to King Edward VII Hospital, Windsor. He was born in 1855, and was the eldest son of the late Dr. James Ellison of Windsor. He was educated at Eton, University College, Oxford, and St. George's Hospital. After taking the diploma of M.R.C.S. Eng. in 1882 he graduated M.B. Oxon. in 1884, and proceeded M.D. in 1895. Dr. Ellison was a remarkable athlete in his younger days. Besides winning distinction as a footballer and gymnast he rowed twice in the Eton eight, was thrice in the head of the river crew at Oxford, rowed against Cambridge in 1878, and won many rowing and sculling prizes at Oxford and at Henley. His career as an oarsman culminated in 1880, when he stroked the Leander eight for the Grand Challenge Cup. After serving as assistant medical registrar at St. George's Hospital he was appointed surgeon apothecary to Queen Victoria's household at Windsor Castle in 1888, and was reappointed by King Edward and by King George. In the Nineties he was acting resident physician to Queen Victoria at Balmoral. He was a member of the Eton College Medical Board, vice-president of the Medical Officers of Schools Association, and vice-president and member of council of the National League for Physical Education. For many years he was associated with the volunteers, and commanded the first volunteer battalion of the Royal Berkshire Regiment, later known as the 4th battalion (3rd line) Royal Berkshire Regiment, Territorial Force. The funeral took place at Eton Cemetery on November 5th, when Canon Sheppard, Subdean of the Chapels Royal, officiated, assisted by the Vicar of Eton.

Universities and Colleges.

UNIVERSITY OF LEEDS.

THE University of Leeds has received with great regret the resignation by Professor A. S. Leyton of the Chair of Pathology and Bacteriology in the University. In accepting this resignation, the University Council has taken the opportunity of recording its high appreciation of the valuable services which Professor Leyton rendered to the university during his tenure of the chair. The question of the appointment of a successor is at present occupying the attention of the university authorities.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual meeting of the Fellows and Members is summoned to meet at the College on Thursday next at 3 p.m., when the annual report will be presented. We mentioned on October 20th that the Society of Members had suggested that, in view of the present great pressure on the time and money of medical men at home and the absence of so many members abroad on His Majesty's Service, the meeting should not be held. The Council of the College decided otherwise, but at the annual meeting of the society on October 30th the action of its council was confirmed. Consequently no resolution will be submitted on behalf of the society at the meeting and no attempt made to attend or obtain a quorum.

CONJOINT BOARD IN ENGLAND.

REVISED REGULATIONS FOR THE PRELIMINARY EXAMINATION.

THE revised regulations of the Royal Colleges of Physicians and Surgeons in England relating to the Preliminary Examination required for the diplomas of the Royal Colleges come into force at once. Latin is now an optional subject, and a larger range of optional subjects has been adopted. A candidate must pass in: (a) English; (b) mathematics; (c) one of the following languages: Latin, French, Russian, German, Italian, or Spanish; (d) a second language selected from the foregoing list or one of the following subjects: higher mathematics, experimental mechanics, chemistry, physical geography, physics, botany, biology, geology.

The Services.

EXCHANGE.

CAPTAIN R.A.M.C., who has served a year in France at a base hospital, desires an exchange for the winter months with a medical officer in England.—Address, No. 3600, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.2.

Medical News.

MR. O. F. N. TREADWELL, F.R.C.S., assistant medical inspector of prisons, has been appointed one of the Commissioners under the Prison Act, 1877.

PROFESSOR S. D. ADSEAD, F.R.I.B.A., will lecture at University College, London, on November 15th, at 5.30 p.m., on "Some general aspects of town-planning after the war," under the presidency of Sir William Collins, M.D., M.P., chairman of the Chadwick Trustees.

THROUGH the generosity of Miss Chalmers, a block for incurables has been opened in the beautiful grounds of the Christchurch Hospital, New Zealand. The block consists of three stories, and from its roof there is a magnificent view of the plains and surrounding mountains.

DR. CHRISTOPHER ADDISON, M.P., Minister of Reconstruction, will give an address on "Health problems and reconstruction" at a meeting which the Faculty of Insurance has arranged at the Central Hall, Westminster, on Saturday, November 24th, at noon. Mr. Kingsley Wood, L.C.C., will preside.

A SERVICE was held on November 2nd, in the chapel of the National Hospital for the Paralysed and Epileptic, Queen Square, Bloomsbury, in commemoration of founders' day. The service was conducted by Canon Edgar Sheppard, and among those attending were Lord Beauchamp, president of the hospital, Sir Frederick Macmillan, Dr. James Taylor, and Sir James Crichton-Browne.

THE following are among those recommended for election into the Council of the Royal Society on November 30th: Dr. Hugh Kerr Anderson (Cambridge); Professor G. C. Bourne, Linacre Professor of Comparative Anatomy, Oxford; Dr. A. R. Cushny, Professor of Pharmacology, University College, London; Dr. W. H. Lang, Barker Professor of Cryptogamic Botany, University of Manchester; Dr. W. H. R. Rivers (Cambridge), and Professor C. S. Sherrington (Oxford).

THE American Red Cross in France has arranged to publish a small monthly journal, the *Medical Bulletin*, containing abstracts of articles appearing in British, French, and American periodicals. This journal will be distributed free to American medical officers, and to officers of other armies on request. The arrangements are in the hands of Dr. Kenneth Taylor, director of the Robert Walton Goelet Research Fund, 6, Rue Piccini, Paris.

RECENTLY published official statistics show that in 1911 the number of deaf-mutes in Italy was 27,608, and of blind

persons 28,357. As regards the regional distribution of deaf-mutism, Lombardy headed the list with 5,363. Piedmont coming next with 3,496. The largest number of blind persons was in Sicily, where the number was 3,462, Tuscany coming next with 2,705.

A SERIES of seven drawings of the London Hospital, by Mr. Hanslip Fletcher, have been reproduced in gravure by Messrs. W. H. Benyon and Co., Cheltenham. They include sketches of the characteristic heavy main front of the hospital, a view from the garden, and a view of the medical college. There are four drawings of interiors—the great hall of the out-patients' department, the receiving room, the lupus light room, and the library of the medical college. The drawings are excellent examples of Mr. Fletcher's skill in interpreting architectural features, and will appeal strongly to old students of the hospital. The subscription price for artist's signed proofs on India paper, with plate paper mounts, is 42s. the set (portfolio 5s. 6d. extra). In this form they can be sent abroad. The publishers will supply them in this country in oak frames at an extra charge of 31s. 6d. the set.

DR. T. BRAILSFORD ROBERTSON, professor of biochemistry and pharmacology in the University of California, has executed a deed, giving to the university all his patent rights in tethelin. This substance, extracted from the anterior lobe of the pituitary body, is reported, as was noted in the *JOURNAL* of September 29th, p. 430, to have a remarkable influence in accelerating the growth of granulation tissue. It is stated to be of value in curing wounds and in causing old-standing wounds to heal promptly. The profits resulting from the sale of tethelin are to constitute an endowment, vested in the regents of the University of California, who will apply the income to medical research. The researches will be supervised by a board of directors. The University of California believes that the establishment of this foundation may serve as a pattern of procedure by which others may dedicate the results of their scientific discoveries to the benefit of mankind as a whole.

A MEETING of the West London Medico-Chirurgical Society was held under the presidency of Dr. A. J. Rice-Oxley at the West London Hospital on November 2nd, when several cases of interest were shown. Major McAdam Eccles demonstrated by means of photographs and microscopic slides an unusual case of hermaphroditism. The subject had the external sexual characteristics of a female, but testes in a low state of development were present and a uterus was absent. Drs. Grainger Stewart and Reginald Morton showed a case of oesophageal diverticulum, in which some of the symptoms in this condition, usually regarded as cardinal, were absent. The pouch was excellently seen in the skiagram. Dr. Morton also showed a skiagram of a stomach distended with a large hair ball, in which the diagnosis was made by means of x-rays and afterwards confirmed at operation. Mr. Aslett Baldwin showed a man who had been operated on for the removal of calculi in both kidneys and the left ureter and now had hernial protrusions from all three operation wounds; he had, moreover, quite recently submitted to operation for radical cure of left inguinal hernia. Drs. A. E. Saunders, Souttar, Owen, Pernet, and Quesada exhibited other cases, or skiagrams of cases, the latter in conjunction with Dr. Morton. Discussion followed.

AN annotation in the current number of the *British Journal of Ophthalmology* makes out a strong case for reform in the regulations for eyesight tests laid down by various departments of State. It is stated that while visual acuity, for instance, is gauged by Snellen's test types, nothing is done to ensure that the conditions under which the tests are applied shall be comparable to the standards. No official regulations of any department state the illumination of the standard. This is unfair to the candidates for Civil Service appointments. If an appeal from the decision of the ordinary examiners is allowed the candidate may have to pay a fee for the further examination, yet the conditions under which such appeal examinations are carried out often, it is stated, leave much to be desired. The remedy proposed by our contemporary is that the many regulations relating to eyesight now in force should be revised by a committee of experts appointed by the Government after consultation with the Ophthalmological Society and the Ophthalmological Section of the Royal Society of Medicine, and that this committee should act as a standing committee of reference which all departments should be required to consult. It is proposed also that one central properly equipped examination hall, provided with dark rooms, laboratories, and so forth, should be available for the use of all departments.

Letters, Notes, and Answers.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and *JOURNAL* are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

A CORONER ON THE DUTIES OF MEDICAL MEN.

AN inquest was held on October 20th, at Nuneaton, on a boy aged 9, who died from convulsions due to acute gastritis set up by eating raw apples. The father's evidence was that on October 16th the boy was indisposed, and during the night vomited pieces of raw apple. Next morning the boy was no better, but witness did not think it necessary to fetch a doctor, and, although the vomiting continued during the next day, he still did not think a doctor was needed. The following night the boy had a fit, and witness went for a doctor, who said that he did not go out at night, but suggested that the child could be brought to him wrapped in a blanket, or that another doctor should be called in. The next morning the medical man was sent for again, but when he arrived at midday the boy was dead. The medical man, in reply to a question from the foreman of the jury, said that he had been working very hard the previous day until the early morning. The coroner then observed that there was an erroneous idea abroad that a doctor was bound to attend a patient as soon as called. He pointed out that a doctor must have some rest. In this case the medical man had quite exonerated himself by telling the father to call another doctor, or bring the lad to him. The coroner's remarks seem to have had a steadying effect upon the jury, who brought in a verdict in accordance with the medical evidence, and expressed the opinion that the father would have acted more wisely if he had called in other advice.

GLYCERIN IN THE TREATMENT OF WOUNDS.

MAJOR C. W. DUGGAN, R.A.M.C., O.C. Military Hospital, Lincoln, writes: In 1916 I used liquid paraffin as a substitute for glycerin in the treatment of gunshot wounds, but I found that healing was delayed by its not proving a satisfactory application for osmotic action. The various pastes recommended have the same drawback. Provided necrosis, foreign bodies, etc., are removed from a wound, and one of the many much advertised antiseptics is used, suppuration occupies a very limited period in the healing of a large gunshot wound. It is in the second stage that glycerin with an antiseptic is so useful, and for it there is in my opinion no substitute. Most observers omit all reference to osmosis in the healing of wounds.

GERMAN "SCIENTIFIC" WARFARE.

SOME time ago Dr. Georg Friedrich Nicolai, formerly physician to the Imperial family of Germany and Professor of Physiology in the University of Berlin, was condemned to reduction in military rank, detention in a fortress, and confiscation of his property by way of punishment for the publication of a book on the biology of war. In it he described the degradation of the German military character caused by the war. In illustration he stated that a military officer of the highest rank had asked him whether it would be possible to throw behind the enemy's lines bombs containing cholera germs or plague bacilli. On the professor's reply that such a procedure would be inhuman, the officer contemptuously replied: "In this war humanity has no place and it is lawful for Germany to do everything that may be to her advantage." Nicolai adds that millions of Germans are of the same way of thinking. A doctor on the General Staff asked him whether it would not be possible to inoculate Russians with bacteria, adding, "With such cattle, everything is lawful."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive posts, restant letters addressed either in initials or numbers.

The FitzPatrick Lectures ON MEDICINE IN ENGLAND DURING THE REIGN OF GEORGE III.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON.

By ARNOLD CHAPLIN, M.D., F.R.C.P.,

PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

I. GENERAL CONDITIONS—MEDICAL EDUCATION.

THE sixty years of the reign of George III witnessed vast intellectual changes which closed for ever the long period of feudalism. They saw the practical application of methods of thought which had been taking definite shape for the previous hundred years. They heard the death knell of principles which had enthralled and fettered Europe for centuries, and they saw the foundations laid of those conceptions of civil and intellectual liberty which have since governed the world. It was an age in which the principle was firmly established that free inquiry was the only sure road to the advancement of knowledge, toleration of opinion, and liberty of action.

But although this spirit of free inquiry was abroad in the land, and although its cause was championed by some of the mightiest intellects of that or any other age, yet for a considerable time its victory hung in the balance. Its full fruition was postponed for a number of years, for, in the course of its advance, the spirit of free inquiry met with a most powerful and determined opposition in a reactionary spirit which stood sullenly at bay, and during the last thirty years of the eighteenth century nearly succeeded in wrecking the whole movement.

This age is, perhaps, better known to us than any other in the annals of our history, and its close proximity to our own will surely elicit a measure of our interest and sympathy. The opulence of its literature has made us familiar with its customs, its manners, its great men, and its great women. The lives led by the people of that time, their formal old-world courtesy, their robustness of character, even their foibles, all appeal to us, and occupy a share of our affections. Then, again, the age of George III is adorned by some of the greatest names this country has ever produced. It is hallowed by the memory of Burke the first of political philosophers, of Fox the foremost champion of civil and religious liberty, of the stately Gibbon, of the endearingly simple Goldsmith, of the quartette of great Scotsmen, Hunter, Hume, Adam Smith, and Robertson, and of the commanding and representative personality of Johnson, better known, and dearer to us, perhaps, than any other.

If the foregoing be admitted as a true interpretation of the spirit of the age of George III; if it be granted that this age witnessed great general changes in thought and action, great advances in human progress, and the germs of that social and intellectual state under which we at present live, then it will surely follow that the same processes were in operation in the particular realm of medicine, and produced most important changes therein. It becomes, therefore, a matter of interest and profit to trace these changes; for I venture to think we shall find evidences, in such a study, of the inception of many customs, methods, and theories which have become accepted facts at the present time.

In order to accomplish this purpose it is proposed to attempt a description of the state of medicine during this period.

The proper appreciation of the particular quality of medical thought during the reign of George III involves a consideration of all thought and literature at that time. The last half of the eighteenth century was an age of transition, in which the human intelligence refused to be satisfied with mere speculations, in which it objected to accept ideas as true on the *ipse dixit* of so-called authority, and in which it evinced an overmastering craving for proof. In the second half of this century doctrines which had withstood the assaults of ages were seen to crumble and wither when subjected to the unrelenting process of investigation founded on a secure scientific basis. The same scientific method carried the thoughts of men to heights hitherto unscathed, and opened up vistas of knowledge never

before conceived. The honour of having wrought this change in thought belongs to the French school, of which the chief exponents were Voltaire, Montesquieu, and Rousseau. These men nurtured and brought to fruition the spirit of free inquiry and toleration, and although they borrowed the idea from Locke, Hobbes, and others in this country, they are nevertheless entitled to praise for having clothed it with their genius and imagination.

The first evidence of a change came in the domain of historical writing. Owing to the influence and incessant labours of Voltaire, history for the first time came to be written from a rational standpoint. In his *Le Siècle de Louis XIV* for the first time it was no longer a narration of the trivial acts and peculiarities of kings and captains, but an exhaustive inquiry into the manners, customs, and economic conditions governing the destinies of peoples. After this almost every branch of literature and thought was involved in the same change, until in the closing years of the eighteenth century was witnessed the final emancipation of the human intellect, the last struggles of feudalistic principles, and the dawn of civil, intellectual, and religious freedom. This beneficent stream of unfettered thought was at first without channels, and, with the flood-gates wide open, it bid fair to swamp the very things it was intended to conserve and foster. But as time went on it became more and more directed, until early in the nineteenth century it was so controlled that its full benefits became manifest in every department of life and thought. In a word, the spirit of scientific inquiry became universal, and the days of mere speculation were numbered.

When we come to consider the evolution of medical thought during this epoch, little difficulty is experienced in instituting a parallel with the change that had taken place in intellectual Europe. Until the end of the eighteenth century the spirit of scientific inquiry and the desire to appeal to facts ascertained by experiment did not influence medical thought to any great extent. Harvey, the glory of this College, was so in advance of his time that he was doomed to wait a century for that suitable soil on which his seed could come to fruition. Indeed, we are forced to the conclusion that medical thought during the first half of the eighteenth century accomplished scarcely anything that has withstood the test of time. The theories of medical science then promulgated were often the results of metaphysical speculations, and little or no attempt was made to submit them to the supreme tests of scientific proof. For this reason the systems, raised up with so much labour, and at the expense of such great philosophical ability, were soon swept away when tested by the experimental method.

After giving due attention to these various systems, it must be confessed that one rises from the task with a feeling of sadness—sadness that such powerful intellects wasted their abilities on work calculated so little to contribute to the real advancement of medical knowledge. Indeed, to express shortly our view of the effects produced upon medicine by the systems, we might, with slight substitution of words, adopt a passage from Lord Morley's *Voltaire*, and say, "For all the systems we see only dismal tracts of medical darkness, we hear only the humming of the doctors, as they serve forth to men thirsting after knowledge, the draft of a medical superstition."

The comparative absence of medical advancement during the first half of the eighteenth century can scarcely cause astonishment if the particular education and environment of physicians at that time be taken into account. Those who championed the new scientific method of inquiry were never weary of pointing out that much of the inability of thinkers to advance, and many of the misconceptions that had arisen concerning the fundamental principles of life, were largely due to the influence of the particular teaching then in vogue. They pointed out that a system of teaching which directed mental activities to the fixed and the past, was not conducive to an intellectual training for the purpose of advancing on new, and therefore untrodden, paths of thought. If this be true, there can be no doubt that physicians, during the early years of the reign of George III, lacked, as a rule, that particular kind of training, for they were largely under the influence of this special form of teaching. In many of them erudition in classical attainments far outweighed their eminence in medicine, and was, indeed, their chief claim to distinction. Their special mental training encouraged them to place more reliance upon speculative theorizing concerning

disease than upon the meaning of facts and conditions observed at the bedside and on the *post-mortem* table.

But a change for the better was close at hand. Early in the reign of George III the work of Morgagni began to produce an effect upon medical thought in England, and soon many physicians were engaged in obtaining a real knowledge of disease from the study of morbid conditions found after death. The logical consequence of the work of Morgagni found expression in the labours of Baillie and Bichat, both of whom carried the subject forward. These prominent men were the real fathers of modern pathology and medicine. They occupied positions similar to those of Voltaire and Montesquieu in thought, Burke in politics, and Newton in natural philosophy. They were bold innovators, who swept away an ancient order of things which had long cumbered the ground and defied advance. They established on lines never since departed from, the only rational study of disease. Our debt to them can scarcely be expressed in words.

II. THE CONDITION OF THE MEDICAL PROFESSION IN THE EIGHTEENTH CENTURY.

Having thus summarized the general state of medical thought as it existed at the beginning of the reign of George III, it now becomes necessary to study the more intimate conditions found in the medical profession at that time.

During this reign the medical profession was divided into three grades—physicians, surgeons, and apothecaries. In London, and for seven miles around, these three divisions were governed respectively by the College of Physicians, the Corporation of Surgeons, and the Society of Apothecaries. But beyond this area none of these bodies exercised any very effective control over its members and its privileges. It therefore came to pass that many practitioners resided in the provinces who owned no allegiance to those bodies, and often possessed no legal title to practise either medicine or surgery.

The Ratio of Practitioners to Population.

It is difficult to arrive at any correct estimate of the numbers of practitioners in England at this time, for although the registers of the three licensing bodies can be consulted, they contain a small proportion only of the total. There is, however, one important source of information from which a fairly accurate estimate of the numbers engaged in practice can be obtained. In 1779 Dr. Samuel Foart Simmons, physician to St. Luke's Hospital, published the *Medical Register*. This was the first attempt to gather into one volume particulars of the medical profession and its activities. Unfortunately, only three issues were made, but in the last, which appeared in 1783, data are found from which an estimate of the numerical strength of practitioners resident in England may be made. From an investigation of this invaluable book, only three copies of which are known to exist in London, it is ascertained that in 1782 4,459 medical men were resident in England and Wales, to serve a population estimated at 7,814,327 souls, or one medical man for every 1,752 people. Of this number, 774 doctors were resident in London, with an estimated population of 650,845, or one medical man to every 840 inhabitants. The subject of overcrowding in the medical profession has been ventilated frequently of late years, but when the ratios just given are compared with those obtaining at the present day, no very marked difference will be found. At the present time about 25,000 practitioners in England and Wales serve a population of about 36,000,000, or one to every 1,440 people, while in London about 6,500 doctors attend about 4,500,000 people, or one to every 705 inhabitants. The author of *A Picture of the College of Physicians* estimated that in 1817, London, with a population of 1,100,000 had in residence 1,098 doctors, or one to every 1,000 people. Nor can it be said that the scale of remuneration for medical services rendered has altered to any considerable extent. Physicians in those days charged a guinea, at a time when the purchasing power of the sovereign was far greater than it is now. Indeed, it may be safely stated that a relatively larger number of physicians secured a handsome competence from the practice of their profession in the reign of George III than is the case at the present day, while some, such as Lettsom, Warren, Simmons, and Battie, realized large fortunes.

According to the *Medical Register* for 1783, London contained 149 physicians, 274 surgeons, and 351 apothecaries. This return takes no account of many who, owing to the laxness of supervision, sold drugs and practised surreptitiously without any proper authorization, and the same remark applies with greater force to the provinces. The College, jointly with the Master and Wardens of the Society of Apothecaries, had the power of supervision over drugs sold by apothecaries, but towards the latter part of the eighteenth century a new order had arisen, which, as we shall see, made it necessary to recast the laws and regulations governing the apothecaries. This new order was the druggists, and over these neither the College of Physicians nor the Society of Apothecaries had any jurisdiction.

An investigation of the composition of the College of Physicians, and of the parts of London favoured by those belonging to it during this reign, is of considerable interest. In 1746 the College was composed of 54 Fellows and 24 Licentiates. Of these, 47 resided in the City and 14 in the west end. In 1782 there were 43 Fellows and 74 Licentiates, of whom 35 lived in the City and 42 in the west. The migration from the City to the west had now begun to be marked, and in 1817 out of 89 Fellows and 224 Licentiates, 32 only lived in the City, while 105 practised in the west. From this time the exodus from the city progressed steadily, until at the present day two Fellows only remain to uphold the honour of the College in the heart of the greatest city in the world.

An examination of the number of Fellows and Licentiates admitted is also instructive. From 1760 to 1820 inclusive, 128 Fellows were created, or an average of 2.1 per annum, and during the same period 416 Licentiates were admitted, or an average of 6.9 per annum. During the last thirty years of George III's reign the influx of Licentiates became pronounced, and at the end of the reign they outnumbered the Fellows in a proportion of nearly three to one. The preceding account will, I trust, give a sufficient description of the numerical state of the profession, and will indicate the relatively small numbers of which it was composed.

Medical Laws and Regulations.

I now proceed to a consideration of the laws and regulations under which the medical profession worked at this period. No central authority possessing powers under parliamentary Acts existed, but the three corporate bodies of the College of Physicians, the Corporation of Surgeons, and the Society of Apothecaries respectively exercised jurisdiction over the physicians, the surgeons, and the apothecaries. But even then the power to assert authority by these bodies was limited and often exhibited in a lax manner. As might be supposed, their charters, granted in a bygone age, were ill adapted to new and constantly changing conditions. They referred rather to the profession resident in London, and contained no strict provisions for the governance of those of their members who resided in the provinces. The College of Physicians had ample authority over all physicians engaged in practice in London, and no physician could pursue his vocation in the metropolis and seven miles around without a licence from the College after having been duly examined. Also, by the first statute (14 and 15 Henry VIII. c. 5), which confirmed the charter, the College was given power to examine and grant a licence to all physicians in England, with the important exceptions of graduates in medicine of Oxford and Cambridge. Over them it had no jurisdiction so long as they practised in the provinces. Previous to the granting of the first charter of the College, the right had been conceded to the Bishop of London and the Dean of St. Paul's, with the assistance of physicians and surgeons, to examine and grant licences to those wishing to practise. The same right was also given to a bishop or his vicar-general in the provinces. Even so late as 1687 some bishops continued to exercise this right, and the practice was not discontinued until the College issued a warning on the subject to each bishop. In addition to its other powers, the College was possessed of the right of entering apothecaries' shops in order to inspect the drugs sold.

In much the same way the Corporation of Surgeons and the Society of Apothecaries exercised jurisdiction over members of their bodies, but the control was far less efficient than that of the College. In London it was fairly effective, but in the provinces it left much to be desired.

This failure of control, especially so far as regarded the Society of Apothecaries, was due to the fact that it had no authority over those who were not members of the society. Consequently a large body of practitioners came into existence, and soon caused considerable alarm. These men were not members of any legally constituted body; they held no diploma entitling them to practise medicine and surgery; but, nevertheless, they carried on their business without let or hindrance. Soon they formed the majority of the medical profession, but no power existed by which they could be brought under control. In London these buccaneers of the profession could be dealt with efficiently, but not so in the provinces. According to John Mason Good, these men were merely druggists who, in addition to selling drugs, compounded and dispensed medicines, and practised medicine and surgery. They sold pure drugs to the apothecary, but reserved the impure drugs for their own use. They were unversed in Latin, and could not, therefore, read prescriptions. They first made their appearance at about the end of the seventeenth century, and towards the end of the eighteenth century they had become so numerous that it was felt on all sides that something should be done to bring them under some sort of control.

The Apothecaries Act, 1815.

The result of this incursion of unqualified and ignorant men into the medical profession was the passing of the Apothecaries Act in 1815, but before that could be done public opinion had to be roused concerning the danger. In this agitation for a better state of things the names of John Mason Good and George Man Burrows stand out prominently, and it was owing almost entirely to their powerful advocacy that the reform was brought about. The former founded the "Pharmaceutic Association" in 1794, while the latter was responsible for the "Association of Surgeon-Apothecaries," both being devoted to the improvement of the position of that branch of the profession. If they received no encouragement, at least they met with no active opposition from the Colleges of Physicians and Surgeons, and soon the labours of the two associations bore fruit. On August 1st, 1815, the Apothecaries Act became law, and for the first time in the history of medicine in this country cognizance was taken of the principle that all those who practised must first be properly qualified.

By the provisions of the Apothecaries Act all those who kept an apothecary's shop were required to pass an examination before examiners appointed by the Society of Apothecaries, and all candidates for the examination had to give proof of having served five years as apprentices. The Master and Wardens were given power to enter any apothecary's shop in England and Wales and to impose fines if impure drugs were found. Finally, no apothecary could recover debts in a court of law unless he possessed a licence to practise.

There can be no doubt that the passing of this Act marked an immense advance in the regulations for the control of the profession, and it was the forerunner of all subsequent Acts. It had, however, its defects, and it would have been well had the two Colleges inquired more closely regarding the consequences of this Act. What was the effect of this Act? At a stroke the education of three-fourths of those who contemplated entering the medical profession was placed under the entire control of the Society of Apothecaries through legal powers granted by Parliament. The Colleges had no voice in the matter of determining the scope of medical education, and could deal only with those belonging to their own bodies. It must be admitted that their policy was somewhat short-sighted, for it would have been a comparatively easy matter to adjust their relations with the Society of Apothecaries in such a manner that a share of the control conferred by Parliament would have fallen to their lot. As it was, the Colleges were shut out from all participation in the control of the greater number of the profession, and many years had to elapse before they regained their power.

III. MEDICAL EDUCATION.

I now come to a consideration of the facilities existing for the acquirement of medical knowledge during this period, and to inquire concerning the standard deemed necessary. At this time the three capitals of the British

Isles were the only centres at which medical education could be obtained, and with regard to the number of students, London and Edinburgh were much ahead of Dublin. In London seven general hospitals were established where a knowledge of medicine could be obtained. At Guy's, St. Thomas's, and the London Hospitals systematic courses of lectures in the theory of medicine, materia medica, chemistry, and clinical medicine were given, but in most of the other hospitals the teaching was sadly neglected. Too often the members of the medical and surgical staffs considered it to be no part of their duty to give instruction except to a few favoured pupils from whom they took a premium for the privilege.

As a rule, the subjects of medicine, materia medica, anatomy, and chemistry were taught at schools and lectures supported by private enterprise, of which there were many in the metropolis at the time. In the *Medical Register* for 1783 a page is devoted to a list of lectures, and of the nineteen given there, all were supported by private enterprise, with the exceptions of those at the London, St. Thomas's, and Guy's Hospitals. Indeed, it appears that Dr. George Fordyce of St. Thomas's, Dr. William Saunders of Guy's, and Dr. Maddocks of the London were the only physicians who gave systematic courses of lectures at the institutions to which they were attached. In the same manner midwifery was taught by means of private lectures given by Denman, Osborne, John Clarke, and David Davis. Prominent among these private lecturers was Dr. George Fordyce, who lectured for thirty years on physis, materia medica, and chemistry at his house in Essex Street, Strand. He was assiduous and unremitting in his work; beginning at seven in the morning, he delivered three lectures, each lasting an hour, on six days in the week, and probably nearly all students coming to London at this period passed through his hands. The teaching of anatomy was carried on chiefly at the school in Windmill Street, where the brilliant abilities of the two Hunters, Hewson, Cruickshanks, Wilson, and Baillie made it deservedly famous. Mr. John Shelden and Dr. R. Maclaurin at their respective houses also taught anatomy with considerable success.

After a student had attended lectures and the practice of a hospital for a sufficient length of time, which varied at different periods, he was free to present himself for examination at the Corporation of Surgeons, or the Society of Apothecaries, and if he satisfied the examiners he was granted a diploma. Often however, he did not follow this course, but after studying medicine and surgery, betook himself to the provinces and began practice as an apothecary without any diploma. He was quite secure, and no law could reach him so long as he kept away from London.

When, however, a student decided to practise as a physician, the course to be pursued was different and far more exacting. It was necessary for him to obtain a degree in medicine in some university and in due time to submit himself to the examination for Licentiates at the College of Physicians. This course was obligatory for all physicians except those who chose to practise in the provinces, in which case the possession of the M.D. of either Oxford or Cambridge exempted them by statute from being obliged to become Licentiates. From all accounts the examination for the Licence of the College, which was conducted in Latin, was thorough and searching. It not only established the fact that a successful candidate was learned in medicine, but it proved also that he was a man of considerable erudition and culture. The examination for the candidate for the Fellowship was precisely the same as that for the Licentiate, and the College could justly claim that the members of their body were men of far higher mental attainments than those of the Corporation of Surgeons and the Society of Apothecaries.

At the universities of Oxford and Cambridge the professors of physis and anatomy gave courses of lectures, and so also did the professors or readers of anatomy, botany, and chemistry, but the reading of these lectures appears to have been of a somewhat perfunctory nature, and no practical instruction seems to have been given. Those who intended, therefore, to become physicians settled at centres in this country and on the Continent where the serious study of medicine could be prosecuted, and, except for the purpose of fulfilling the requirements of the universities in the matter of a medical degree, were hardly ever in residence.

The regulations relating to medical degrees differed at the sister universities, and are difficult to follow with any exactness. According to the author of *An Address to the College*, the method of procedure in granting medical degrees at Oxford was as follows: No person could be admitted to the honour of a doctor's degree in medicine until he had been a member of the university for fourteen years, and had complied with all the exercises required. In other words, he was expected to become a Bachelor of Arts in four years, a Master in seven years, a Bachelor of Medicine in ten years, and a Doctor in fourteen years. The principle, therefore, of a degree in Arts before proceeding to one in medicine was established. For the B.A. degree candidates were required to defend questions in logic, grammar, rhetoric, and moral philosophy; to be examined in the same, and all the examinations and exercises were conducted in Latin. For the M.A. degree the candidate was again required to defend questions in the subjects for the B.A., and, in addition, questions in natural philosophy. He was expected, also, to defend three other questions of any kind, and to read six lectures, in the Latin tongue, in natural and moral philosophy. Lastly, he had to pass an examination in geometry, metaphysics, optics, physics, history, geography, chronology, Latin, and Greek. The exercises for the same degrees at Cambridge appear to have been similar, but perhaps more latitude was allowed to candidates in specializing in particular subjects. Now, whatever may have been the way in which these exercises were kept in the letter—and many asserted that they were a mere farce—there can be no doubt that in the spirit they contained the framework of a comprehensive intellectual training. Indeed, those who relied on the system at the two universities as the best preliminary course for physicians, could point with truth to the regulations in force to prove their argument. For the M.B. degree the candidate was required to defend two subjects in physic for two hours, and to oppose two others for a like period. In 1760, according to Dr. Wells, the Act for the M.B. degree consisted of reading the *Aphorisms* of Hippocrates. However that may be, the candidate was obliged to go through a course of anatomy before proceeding to keep the Act. For the M.D. degree the candidate was required to explain a whole book of Galen in six extempore, or three written, lectures.

At Cambridge, perhaps, a more pronounced attempt was made to impart medical knowledge by means of lectures, and the professors appear to have performed their functions with some show of energy. The degree of Bachelor of Medicine could be taken six years after admission, provided that the candidate had kept nine terms at the university. Two public disputes had to be maintained in Latin by the candidate. One question was chosen by the candidate, and the other by the professor. The candidate then read a thesis on his own question, and defended it and the professor's question against the arguments of the professor and other doctors present. Finally, the professor read his "determination" in Latin. This proceeding was conducted in public, and, as a rule, many spectators were present. The degree of M.D. could be taken five years after the M.B., and the exercises required were on the same lines as those for the M.B. Dr. Wells states that originally the candidate was obliged to oppose another candidate, but that this regulation was abrogated on the payment of a fine of twenty shillings. He also asserted that the professor's question could be obtained by the candidate at any time, however long, before the Act was kept. At Cambridge and Oxford a doctor's degree in medicine was sometimes given by royal mandate, and apparently it was not always obligatory to proceed in Arts before taking the M.B. degree, although this course was generally pursued. The foregoing, then, is a picture of the course of education followed by many of those who desired to become physicians. The tendency of that education was in the direction of general culture, and accounts for the high order of mental attainments which was such a prominent feature of the College of those days. In other universities the same spirit prevailed, but the insistence on general knowledge was far less pronounced, and more attention was paid to the special subjects connected with medicine. An education acquired at a university in the days of George III gave a man a more marked distinction from his fellows than it does in our day.

IV. THE ESTABLISHMENT OF DISPENSARIES.

In close association with the facilities for acquiring medical knowledge was the rise and development of the dispensaries in London, one of the most remarkable features in the medical history of the reign. So far back as 1696 an attempt had been made by this College to establish a dispensary for the benefit of those who were too poor to purchase pure drugs, but after a time the project fell into abeyance. With that single exception, no dispensary existed in the metropolis until 1770, when the General Dispensary in Aldersgate Street was founded. This was followed in 1774 by the Westminster General Dispensary, and between that date and 1820 no less than twenty-four similar institutions came into being, of which fifteen remain in active work at the present day.

The need for increased facilities for the medical treatment of the poor of growing London, and the wider conceptions in vogue concerning the duties of the rich towards the poor, no doubt, were largely responsible for the foundation of the dispensaries. Many of these institutions, however, owed their origin to the insistent demands of energetic physicians who, supported by their influential friends, desired a field for clinical work. At that time physicians of great ability were beginning to flock to London; the possibilities of obtaining positions where they could found professional reputations as teachers were limited, and the staffs of the hospitals were small. In this difficulty the more enterprising spirits threw themselves with ardour into the project, and so it came about that the dispensaries were staffed by some of the ablest and most enlightened physicians in the town. The names of Lettsom, James Sims, Hulme, Simmons, Willan, Wells, and Cooke are prominently associated with this movement, and some of the dispensaries, such as the "General," the "Westminster," and the "Public" soon became centres for teaching, and the excellence of the clinical instruction attracted many students. A particular interest attaches to the Public Dispensary in Carey Street, for it was there that Robert Willan and his pupil Thomas Bateman prosecuted their researches in dermatology and gave to the world the first attempt to classify skin diseases from an anatomical standpoint.

Many special hospitals and institutions also began their activities in this reign, or a few years before its commencement. Thus, between the years 1749 and 1820, seven lying-in hospitals and dispensaries, three institutions for venereal disease, three vaccine establishments, one fever hospital, and one lunatic asylum were founded in London; surely a worthy testimonial to the medical progress of the age and the energy of the physicians.

V. MEDICAL SOCIETIES.

Further evidence of the medical activity of this reign is found in the rise of the numerous societies devoted to the advancement of medicine. Probably the earliest society of this kind of which we have any record was one founded by Glisson about 1650, and mentioned in his work on rickets. The next was the Society of Naval Surgeons, which began its career in 1746. This society engaged Mr. Sharp to deliver lectures on surgical operations, and met at a house in Covent Garden. Sharp was soon succeeded by William Hunter, who continued the course for several years. In 1752 a medical society was formed, chiefly owing to the energy of William Hunter, and met at the Mitre Tavern. The next to be founded was the "Medical Society of Physicians," in 1764, by John Fothergill, and one of its presidents was William Hunter. Licentiates of the College only were eligible for election, and the meetings were held at Old Slaughter's Coffee House, but once a quarter the members dined at the Crown and Anchor. In 1767, at the instigation of Dr. Heberden, the "Meetings of the College of Physicians" were begun, and between that date and 1820 six volumes of transactions were issued. The year 1771 saw the establishment of the "Guy's Physical Society" by Dr. William Saunders, and the same year witnessed the foundation of the "Physico-Medical Society." In 1773 the "Medical Society" was founded, and in the following year the "Middlesex Hospital Society" began its career. Mr. Shelden formed a medical society in 1779, which met at his house in Great Queen Street, and in 1782, owing to the efforts of Dr. Simmons, Dr. Fordyce, and John Hunter, the "Society for the Improvement of Medical Knowledge"

was formed, the meetings being held at Old Slaughter's Coffee House. Fordyce was also responsible for the foundation of the "Lyceum Medicis Londinense" in 1785. Finally, the "Abernethian Society" was established in 1795, the "Medico-Chirurgical" in 1805, and the "Hunterian" in 1819. A society of Physicians to Dispensaries met in the Borough about 1780, but the exact date of its foundation is uncertain.

It will thus be seen that twelve medical societies were formed during the reign of George III, and three only before that period. Many of them came to an end after a few years of usefulness, but six remain, and are flourishing at the present time. Among those who did so much to encourage the formation of these societies, the names of Simmonds, Fordyce, William Hunter, Fothergill, and Lettsom must for ever be honoured. They toiled, not unsuccessfully, for the advancement of medicine and for a wider medical polity where men holding diverse opinions could meet and exchange their views.

(To be continued.)

THE RELATIVE GERMICIDAL EFFICIENCY OF ANTISEPTICS OF THE CHLORINE GROUP AND ACRIFLAVINE AND OTHER DYES,

WITH OBSERVATIONS OF THE RATIONAL TESTING OF ANTISEPTICS.

BY

H. D. DAKIN, D.Sc., AND E. K. DUNHAM, F.R.S. M.D.

(Report to the Medical Research Committee.)

The object of the following paper is to point out certain common errors in the testing of antiseptics of the chlorine group which lead to totally inaccurate inferences as to their germicidal potency; secondly, to compare the results obtained by methods eliminating these errors with those furnished by other antiseptics; thirdly, to examine the claims made by Browning and his colleagues¹ for the alleged vastly superior germicidal potency of acriflavine and certain other dyes; and, lastly, to indicate how important the matter of the velocity of disinfection is in forming a judgement of the utility of antiseptics in surgical practice, and also the methods suitable for their successful employment.

The Testing of Antiseptics of the Chlorine Group for Germicidal Action.

The instability and reactivity of the hypochlorites and other antiseptics of the chlorine group has long been known. Their ability to react with proteins, peptones, and amino acids to furnish products some of which still possess germicidal properties (chloramines), and others which are entirely inert (chlorides and compounds containing chlorine united to carbon), has been definitely determined. When a relatively large excess of protein acts on minimal quantities of hypochlorite, no chloramine derivatives persist, and the whole of the chlorine is converted into germicidally inactive forms. Notwithstanding these well established facts current literature contains countless examples of experiments in which workers have taken protein-rich media, then added minute quantities of the chlorine antiseptic; subsequently, after an unstated interval, when all or most of the antiseptic has been decomposed, the mixture is inoculated with organisms, and surprise is expressed at their ability to grow unchecked. Under such circumstances the observed results depend much more on the rate of reaction between the antiseptic and the protein medium than upon germicidal action.

In making tests of the germicidal efficiency of any antiseptic there seems to be no good reason for not following the order of mixing the materials indicated by the conditions of their practical use—namely, to add the antiseptic last to the inoculated medium. Under these conditions very different results are obtained with unstable antiseptics, compared with those observed when the organisms are added last. Perhaps the most naive alleged demonstration of the inutility of hypochlorites as antiseptics was that offered by Delbet, who took egg albumen, added a little hypochlorite of undetermined strength, next heated

the mixture for a considerable time, so that all the antiseptic would be decomposed with certainty, and then found, to his evident satisfaction, that streptococci could grow in the residue. Equally enlightening experiments have led various workers into statements as to the excellence of hypochlorite solutions as culture media for *B. capsulatus* and *B. pyocyaneus*, but these entertaining speculations need not be seriously considered.

More recently, however, Browning and his colleagues have published a series of experiments in which the germicidal potency of various antiseptics of the chlorine group is compared with various dyestuffs, with results which apparently indicate an enormous superiority for the latter. Numerical ratios for the relative antiseptic potency of the various substances are given, in which the lethal concentration of chloramine-T tested against staphylococci in serum is taken as unity. The lethal concentration of chloramine-T in serum is stated to be 1:250 without reference to much lower concentrations already published by others. The discrepancy is due, in the main, to the fact that the antiseptic was added first to the medium and the organisms last. No indication is given by Browning of the all-important interval of time elapsing between the two additions. From what has been already stated, it is clear that by this method of procedure irregular results are inevitable.

In the following table, a few new experiments are given, showing the results of the action of chloramine-T when tested against *Staphylococcus aureus* in blood serum and in 0.7 per cent. Witte's peptone, the antiseptic being added last as in actual practice.

In these experiments the medium (2 c.cm.) was inoculated with a suspension in saline of an agar slant growth of *Staphylococcus aureus*. The chloramine-T solution (1 c.cm.) in varying concentration was added last, and at regular time intervals the number of surviving bacteria was estimated by plating. In every case any unchanged antiseptic was destroyed before plating by the addition of sterile sodium thiosulphate solution.

TABLE I.—Chloramine-T.

* 1 drop = $\frac{1}{10}$ c.cm.

From these results it is clear that under the above conditions the lethal concentration of chloramine-T in blood serum is slightly under 1:2,000, and in 0.7 per cent. Witte's peptone between 1:5,000 and 1:6,000. These figures contrast with 1:250 and 1:2,000 respectively given by Browning and his colleagues. The use by Browning of the figure 1:250 for the lethal concentration of chloramine-T against *Staphylococcus aureus* as a standard for calculating the relative antiseptic potency of other substances is clearly misleading.

The fundamental error in Browning's figures for the antiseptic potency of chloramine-T is again encountered in

the case of the still more reactive hypochlorite preparations. A later section of this paper contains experimental results illustrating germicidal action of these and other substances acting in a blood serum-muscle extract medium, and also in defibrinated blood.

Some Factors concerning the Rational Testing of Antiseptics.

It is generally recognized that the testing of substances for their antiseptic or germicidal properties is fraught with innumerable pitfalls, and that by varying the conditions of testing almost any kind of result may be obtained. In the case of disinfectants intended for hygienic purposes, the Walker-Rideal method in one or other of its forms gives a reasonably satisfactory basis for comparison, but with substances intended for wound disinfection, no such standard methods exist. Experiment for the determination of the lethal concentration of the germicide acting on various organisms in water, blood serum, blood, or pus usually are regarded as sufficient, and but little attention is paid to such important factors as the time of action, temperature, and number of organisms present.

A great advantage in the use of serum as a medium for the determination of the germicidal properties of an antiseptic intended for surgical use is the fact that it presents a homogeneous medium of fairly constant composition, but it is important to bear in mind that many organisms are very susceptible to the action of blood serum, even though previously heated to 58-60°. To avoid this complication, large numbers of the organism should be used, and fairly resistant types, such as *Staphylococcus aureus*, should be chosen. The use of blood as a standard medium for the testing of the germicidal properties of antiseptics has been suggested by Emery, and this would seem to be a rational procedure in the case of substances intended for intravenous use. Great difficulties are encountered in securing uniform laboratory experiments on the germicidal action of substances upon pus, largely owing to extreme variations in its composition and physical condition, and whether the infecting organisms are free or ingested in the leucocytes. As a substitute for pus, the use of blood as a test medium is of practical value in throwing light on the action of antiseptics in the presence of cellular elements, though the results will be particularly unfavourable to those substances, such as hypochlorites, which are readily decomposed by haemoglobin.

Usually the lethal concentration for germicidal substances tested under various conditions against different organisms is alone considered. But it is becoming constantly clearer that much more than this is needed to form a judgement of the possible value of an antiseptic for wound treatment. A higher concentration of an otherwise inoffensive germicide may easily prove more useful practically than a lower concentration of a more active compound. The fundamental work of Miss Chick,² following that of Paul and Krönig and Madsen and Nyman, has clearly shown that the act of disinfection resembles in many fundamental respects an ordinary chemical reaction in which the two reacting components are represented by bacterial protoplasm and disinfectant. The rate of disinfection varies enormously with different germicides. The mass of antiseptic and that of the bacteria and other reacting substances, as well as the temperature and intimacy of contact between the reacting substances, all influence the result. A knowledge of the speed of disinfection is important in judging of the most suitable manner in which to employ different antiseptics in actual practice. Thus, as will be seen later, the hypochlorites, chloramine-T, and similar substances in concentrations such as are used in practice act with extraordinary speed, completing in a few minutes or even seconds an amount of disinfection which dyes, such as acriflavine, require six hours or more to effect. But in actual use the hypochlorites and chloramine-T are chemically unstable and need frequent renewal unless disinfection has been completed, while frequent renewal of the dyestuffs would add but little to their effect, and actually they are found to be most useful employed as wet dressings, and not for irrigating. This point has been convincingly discussed by Parry Morgan.³

In order to obtain information as to the relative speed of disinfection exerted by various antiseptics, we have determined the progressive change in the number of bacteria in

suited mixtures after varying lengths of time of action. We have made use of two media—one a mixture of horse blood serum (1 c.cm.) with muscle extract (1 c.cm.), obtained by soaking fresh veal with an equal weight of 0.7 per cent. salt solution and straining through gauze, but not filtering. The other medium was sterile fresh defibrinated rabbit's blood (2 c.cm.). These mixtures were heavily inoculated with a *Staphylococcus aureus* emulsion obtained by shaking a twenty-four-hour agar slant growth with 8 c.cm. of salt solution. After determining the total number of organisms in the mixture by plating an aliquot part, 1 c.cm. of the antiseptic solution was usually added and samples withdrawn from time to time and the surviving bacteria estimated. In most cases the antiseptic was added at about the concentration commonly used for wound treatment, though in the case of some of the more active substances lower concentrations were also employed and occasionally higher ones with the less active substances.

In the case of antiseptics of the chlorine group, their further action in the sample withdrawn for plating was at once checked by addition of an excess of sterile sodium thiosulphate solution, while potassium sulphide was used as antidote with the salts of the heavy metals. No antidote was used in the case of the dyes, and in some cases evidence of inhibition of growth on the plates was noted, due to the mechanical carrying over of some of the dye. The use of the blood serum-muscle extract medium was chosen as bearing some similarity to that in which the antiseptics would be used in wound treatment. It has the further advantage of being easily reproduced in fairly uniform quality. For many antiseptics the addition of muscle extract makes the tests more severe than when blood serum is used alone. The experiments were all carried out at 32-35° C., and the results are all expressed as the number of bacteria present in one standard drop of the mixtures = $\frac{1}{20}$ c.c.u. For convenience, the antiseptics are grouped in three classes—namely, those of the chlorine group, dyes, and metallic salts.

¹ Active chlorine present. ² Active chlorine absent. ³ Mixed with platinum wire. ⁴ Not mixed, left to diffuse.

The results contained in Table II indicate clearly the extraordinarily rapid action of the antiseptics of the chlorine group. All of the solutions of strengths used in wound treatment affected sterilization in the course of five minutes or less. The experiments in which insufficient quantities of sodium hypochlorite or caustol were used (II and IV) show that when their immediate action is over, and no undecomposed antiseptic remains, growth of the surviving organisms readily takes place. The efficiency of chloramine-T added to the extent of 1:600 in the mixture illustrates its more potent action than roughly equivalent quantities of chlorine in the form of hypochlorite or caustol. This is, no doubt, largely due to its slower rate of decomposition in the medium.

* 1 drop = $\frac{1}{10}$ c.cm.

The results of experiments with metallic salts, phenol, and hydrogen peroxide, are recorded in Table III. Mercuric chloride, added as a 1:1,000 solution, is seen to be distinctly more rapid and complete in its action than silver nitrate or zinc chloride, and, though the latter were used in much higher concentration, they did not effect sterilization in twenty-four hours. Argyrol was used in very high

concentration (1:20), and, while it eventually sterilized completely, its action was by no means rapid, and only slightly superior to phenol (1:50). The experiment with hydrogen peroxide illustrates its rapid but very transitory effect, which reached its maximum in a few minutes, with subsequent unrestricted growth.

* 1 drop = $\frac{1}{10}$ c.cm.

The action of the dyes on staphylococci in the blood serum-muscle extract was, on the whole, disappointing. Malachite green and brilliant green, even when added at 1:333 concentration, so that 1:1,000 was present in the

mixture, failed to effect sterilization in twenty-four hours, and by the end of that time the organisms were growing freely. Similar mixtures on exposure at 37° readily underwent thorough putrefaction, so that it is clear that unchanged persistence of colouring matter cannot be regarded as evidence of continuing germicidal action. The experiments with acriflavine indicate a relatively slow action, and even in the higher concentrations a fair number of viable organisms were present after six hours' action. The lower concentration (1:3,333 as added) failed to sterilize in twenty-four hours, and permitted growth so that the final number of organisms had risen above that present at the start.

Browning gives the following lethal concentrations for dyes acting in serum on *Staphylococcus aureus*: Malachite green, 1:40,000; brilliant green oxalate, 1:100,000; acriflavine, 1:200,000. Under the conditions of our experiments the lethal concentration for malachite green and brilliant green is greater than 1:1,000, and for acriflavine between 1:3,000 and 1:10,000.

The relative inefficiency of sodium hypochlorite and eusol acting in defibrinated blood is shown in Table V. This is apparently due to the ease with which sodium hypochlorite is decomposed by haemoglobin. The fact that an equal volume of the ordinary hypochlorite solutions added to blood infected with streptococci is insufficient to effect sterilization has already been noted by Emery. The superior efficiency of chloramine-T compared with equivalent amounts of hypochlorite acting in blood is very marked, and is doubtless due to its slower rate of decomposition already noted.

* 1 drop = $\frac{1}{10}$ c.cm.

† The blood and antiseptic were mixed, incubated twenty-four hours and then the suspension of staphylococci added. In these experiments, therefore, the precipitate occasioned by the dye was produced before inoculation. Comparison of X and XI indicates the probability that many organisms are carried down by the relatively slow formation of a flocculent precipitate. The rapid falling off of the cocci found in the fluid was probably due to this cause, and not to the germicidal action of the dye.

The germicidal action of the dyes in defibrinated blood is in most cases distinctly superior to that shown in the blood serum-muscle extract medium. Malachite green is seen to be distinctly inferior to brilliant green, acriflavine, or proflavine. Neither brilliant green nor malachite green when present in 1:3,000 concentration failed to prevent multiplication of the organisms. Acriflavine and proflavine present in 1:3,000 concentration failed to sterilize in six hours, but usually did so in twenty-four hours, while when present in 1:10,000 concentration the mixture was not quite sterile in twenty-four hours.

DISCUSSION AND CONCLUSIONS.

The main facts disclosed by the preceding series of experiments are as follows: (a) The rapid and complete disinfection brought about by solutions (one volume) of members of the chlorine group of antiseptics of the strength commonly used in the treatment of wounds, when added to heavily infected blood serum-muscle extract mixture (two volumes). (b) Under similar circumstances, solutions of acriflavine, proflavine, brilliant green, and malachite green failed to sterilize in six hours mixtures which the chlorine antiseptics sterilized completely in five minutes or less.

Browning concludes from his experiments that acriflavine is 800 times more powerful against staphylococci in serum than chloramine-T. A comparison of our Experiment VI, Table II, and Experiment IV, Table IV, shows that a 1:600 solution of chloramine-T can sterilize in six hours an infected blood serum-muscle extract which was not sterilized in six hours by 1:1,000 acriflavine. The difference in results is striking and deserves comment. One source of error in Browning's experiments has already been indicated, namely, the addition of the chlorine antiseptics to the blood serum before adding the organisms. We believe another source of discrepancy is due to the fact that Browning and his associates used extraordinarily few bacteria in their tests, namely, 0.1 c.cm. of a 1:20,000 dilution in saline of a twenty-four-hour peptone water culture. A loopful of this mixture plated on agar yielded "twenty or more colonies." It appears to us that the use of such small numbers of organisms is unsuited for the determination of the germicidal value of substances, for, in the first place, such a low concentration of organisms in the secretion of a wound of long standing borders on "surgical

sterility"; hence the experimental conditions are not comparable with those in acute septic wounds. Secondly, if 5 per cent. of the organisms in Browning's tests survived they would have a good chance of being entirely overlooked, and sterility might thus be inferred when viable organisms were actually present. Lastly, the bactericidal properties of the serum medium becomes a significant factor when few organisms are used in the presence of native germicidal substances.

Another cause of the marked difference between our own and Browning's results is the fact that he allowed the antiseptics to act for twenty-four to forty-eight hours before testing, whereas in our own experiments subcultures were taken at frequent intervals, which brought under observation the progress of disinfection. The longer period naturally fosters a favourable judgement of the slowly acting dyes, while shorter periods are adverse to them.

We conclude, therefore, that the statements of Browning and his colleagues as to the relative germicidal efficiency of chloramine-T and other antiseptics of the chlorine group compared with brilliant green, malachite green, and acriflavine, are incorrect, and that their mode of testing the germicidal action of the substances studied by them leads to results which are radically misleading.

DETECTION AND TREATMENT WITH EMETINE BISMUTH IODIDE OF AMOEBIC DYSENTERY CARRIERS AMONG CASES OF IRRITABLE HEART.*

BY

MARGARET W. JEPPI,

BATHURST STUDENT, NEWNHAM COLLEGE, CAMBRIDGE,

AND

J. C. MEAKINS, MAJOR C.A.M.C.

(Report to the Medical Research Committee.)

AMOEBIc dysentery as a direct or aggravating cause of irritable heart was found amongst soldiers returned from the Mediterranean Force.¹ It was therefore considered important, in dealing with this condition, to determine the number of cases of carriers, and to attempt to cure them. From October, 1916, to February, 1917, we examined the stools of all cases from the Mediterranean Force admitted to the Hampstead Military Hospital suffering from irritable heart. No selection of the men was made in so far as the presence or absence of a history of dysentery was concerned. In all sixty-five cases have been examined, of which twenty-five had a definite history of dysentery.

Infections.

The microscopic examinations of the stools were made in the usual way, and we aimed at six careful examinations† at least of each man before discharging him as uninfected. How far we were able to carry this out the following figures will show:

6 or more examinations	51 cases
5 examinations only	1 case
4	8 cases
3	3 ..
2	1 case
1	1 ..
			65

The following infections were detected:

<i>Entamoeba histolytica</i> ...	24 cases = 36.9 % total cases.
<i>Entamoeba coli</i> ...	32 .. = 49.2 ..
<i>Lamblia intestinalis</i> ...	20 .. = 30.8 ..
<i>Chilomastix mesnili</i> ...	3 .. = 4.6 ..
<i>Trichomonas hominis</i> ...	1 case.

Entamoeba nana (Wenyon and O'Connor) was found as the active free amoeba in one case, and its cysts were found in others. Their occurrence was not always recorded, however, so that no indication of the frequency of this infection can be given. The so-called "iodine cysts"

This work was done at the Hampstead Military Hospital. The treatments were carried out by one of us (J. C. M.), and the examinations made by the other (M. W. J.).

* This was done at the suggestion of Mr. Clifford Dobell.

of Wenyon were found in six cases,⁸ and the eggs of *Trichuris trichiura* (= *Trichocephalus dispar*) in two.

The percentages are, of course, of little absolute significance in so small a number of cases. It was to be expected that they would be higher than some of the corresponding figures obtained elsewhere by a smaller number of examinations per case.² That the larger number of examinations accounts, in part at least, for the exceptionally high proportion of infected cases may be seen in the following tables, where the examinations are shown at which infections were detected.

TABLE I.—Infections with *E. histolytica*, *E. coli*, and *Lambliæ*.

Examination at which detected.	<i>E. histolytica</i> .		<i>E. coli</i> .		<i>Lambliæ</i> .	
	No. of cases.	Per-centage of cases.	No. of cases.	Per-centage of cases.	No. of cases.	Per-centage of cases.

2nd ...	3	4.5	5	7.8	1	1.6
3rd ...	4	6.3	5	7.8	3	4.7
4th ...	1	1.7	1	1.7	1	1.7
5th ...	2	3.8	2	3.8	1	1.9
6th ...	2	3.9	1	2.0	2	3.9
Totals ...	23	—	28	—	17	—
8th ...	—	—	1	—	—	—
9th ...	—	—	1	—	—	—
10th ...	1	—	—	—	—	—
14th ...	—	—	1	—	1	—
28th ...	—	—	1	—	—	—
32nd ...	—	—	—	—	1	—
47th ...	—	—	—	—	1	—
Totals ...	24	—	32	—	20	—

The percentages for each examination are worked out on the number of cases which had at least that number of examinations. Table II shows the total number of infections found after each of the first six examinations among the fifty-one cases which had at least six examinations each.

TABLE II.—Infections Found after the Six First Examinations.

No. of Examinations.	<i>E. histolytica</i> .		<i>E. coli</i> .		<i>Lambliæ</i> .	
	No. of cases.	Percentage total cases.	No. of cases.	Percentage total cases.	No. of cases.	Percentage total cases.
1	9	17.6	12	23.5	8	15.7
2	11	21.6	14	27.4	8	15.7
3	15	29.4	18	35.3	10	19.6
4	16	30.4	19	37.3	11	21.6
5	18	35.3	21	41.2	12	23.5
6	20	39.2	22	43.1	14	27.4

It is clear that infections were detected on every examination, including the sixth and last. That even this does not represent the actual total number of infections is demonstrated by the few figures given for still later examinations in the lower half of Table I, which gives the results of twenty-three extra examinations made on twelve negative cases, and of the examinations made during and after treatment on some of the positive cases. These are given merely as further examples of infections not detected in a small number of examinations.

Carriers of *E. histolytica*.

It is of interest to note that among this series of twenty-four carriers in no fewer than twelve no *E. histolytica* cysts measuring over 10μ in diameter were ever observed. These small cysts, measuring $6-10\mu$ in diameter, have been described by several authors,⁴ but rather as an abnormal form of rare occurrence. Such infections may be exceedingly difficult to detect, even when specially looked for, and it has often been necessary to fix and stain films before

a certain diagnosis could be made. The cysts are very easily overlooked when present in the stool in small numbers, particularly if many other small bodies, such as *Chilomastix* cysts, some of the yeasts, pus cells, etc., be present at the same time. For example, Case No. 13 was not found positive until the tenth examination (Table I), although very careful search was made for *E. histolytica*, as large quantities of pus with blood and mucus were usually present in the stool, and the bacteriological report was negative. The cysts were extremely rare and measured about 7μ in diameter. They disappeared after treatment (vide infra), and the clinical condition of the patient improved. The twelve infections in which only small cysts were found were detected as under:

Examinations.	No. of Cases Detected.
1st ... Nos. 23, 24	2
2nd ... Nos. 9, 19, 22	3
3rd ... No. 10	1
4th ... No. 7	1
5th ... Nos. 8, 21	2
6th ... Nos. 18, 20	2
10th ... No. 13	1
	12

These figures, on comparison with Table I, show that in this series it happened that no infection of *E. histolytica*, where typical large cysts were found, was detected after the third examination. This is probably due to chance, and not to the fact that all such infections can be detected in three examinations only. There is naturally a decrease in the number of infections detected at each succeeding examination, and little evidence, if any, that *E. histolytica* differs in this respect from *E. coli* and *Lambliæ*, both of which were sometimes discovered at the sixth and later examinations.²

In one other case (No. 11) the diameter of the *E. histolytica* cysts varied from 7 to 15μ , all intermediate sizes being observed.⁴

Treatment.

Emetine bismuth iodide when given in a powder generally causes nausea and vomiting. In order to overcome these conditions three preparations of the drug were tried. These were experimental preparations made by three different firms, and were submitted to us for trial. They were all in tablet or pill form, and were either mixed or coated with some material supposedly insoluble in the stomach. In all twenty-three courses of treatment were given with these preparations. In no case was nausea or vomiting produced, but in eight cases (35 per cent.) severe diarrhoea and abdominal cramps occurred. Some looseness of the bowels was observed in all cases where the drug appeared to have any action. The results obtained with these preparations are shown below. In these tables "relapsed" signifies that *E. histolytica* was again detected in the stools, and "unaffected" that no negative period was observed during or after treatment.

* Case No. 12 was often negative for a few days while untreated.

Different measures of success were, it will be seen, obtained with these different preparations. With the first preparation there were eight cures out of twelve cases treated, or 66 per cent. With the second there were no cures, while with the third there was only one cured out of four cases treated, or 25 per cent. Of the three preparations, the first was the only one which gave sufficiently good results to justify its use in preference to the drug given in powder (see below). But even the proportion of cures with this preparation is not sufficiently high to warrant its general use.

The objection to the use of emetine bismuth iodide in powder, given in a cachet or capsule, has been the occurrence of nausea and vomiting. We have treated eleven cases with cachets, and these symptoms occurred in all of them. The drug was given with a hot drink at 9 p.m., after the patient was in bed. The time of the vomiting after the drug was taken varied in different individuals, as is shown in Table VI.

TABLE VI.—Occurrence of Nausea and Vomiting.
No. of cases, 11.

Nausea and vomiting occurred during the				
First hour in	0
Second hour in	3
Third hour in	6
Fourth hour in	2

It is evident from this table that the nausea and vomiting occurs most frequently after the stomach is presumably empty. These symptoms fortunately did not persist during the whole course of treatment. The toxic symptoms disappeared after a time as if a tolerance had developed.^{5,6}

Third day in	1
Fourth day in	2
Fifth day in	3
Sixth day in	4
Seventh day in	0
Eighth day in	0
Ninth day in	1

Eleven cases were treated with emetine bismuth iodide in cachets of 3 gr. each. Ten cases (91 per cent.) were cured after twelve daily doses (Table VIII).

* We are indebted to Dr. G. C. Low for facilities for making the last four examinations of this patient, after he had been transferred to another hospital.

The one case which was not cured had previously resisted three courses with the first preparation described above. The results obtained with the drug administered by this method are much more encouraging than those obtained with any of the other preparations.

* Three separate courses.

† See Table V.

All the patients treated were suffering from symptoms of irritable heart. Any possible effects of the removal of the *E. histolytica* infection on the symptoms of this condition were carefully looked for. Of the twenty cases which were cured, eleven (55 per cent.) showed a conspicuous improvement, while nine (45 per cent.) showed little or none. The degree of improvement was determined by their increased ability to perform graduated exercises without untoward symptoms.¹ Cases which, before treatment, showed severe symptoms after performing mild exercises could afterwards accomplish the more

advanced exercises with comparative ease. This confirms the previous conclusion that the removal of a coexisting infection may lead to the alleviation of symptoms of irritable heart.¹

Treatment with Methyl-Psychotrine.

In addition to these treatments with emetine bismuth iodide we tested a new alkaloid, methyl-psychotrine, prepared from ipecacuanha by Dr. F. L. Pyman, and sent to us for trial by Dr. H. H. Dale, F.R.S. Two cases were treated with this drug, the results being shown in the following table:

TABLE X.—Methyl-Psychotrine.

Case No.	Treatment.		Total Amount Given.	Result.
	Began.	Ended.		
11	Nov. 17, 1916	Dec. 6, 1916	108 gr.	Unaffected.
12	Nov. 26, 1916	Dec. 4, 1916	54 gr.	"

As will be seen from the table, the drug appears to have had no effect whatever upon the *E. histolytica* infections in spite of the large amounts administered. Case No. 11 had daily doses of the drug increasing from 2 gr. to 9 gr. Case No. 12, daily doses from 3 gr. to 9 gr. In both cases the drug appeared to be quite non-toxic to the patients. Both were subsequently treated with emetine bismuth iodide, and apparently cured of their infections, as shown in Table VIII. Case No. 11 also had a heavy infection of *Lambli*a, which was not affected by the methyl-psychotrine.

Differential Blood Counts.

Mrs. Briscoe, M.D., B.S.Lond., has very kindly given us the results of some differential counts which she made on some of our carriers. These are shown in Table XI. Mrs. Briscoe says: "They all show the high lymphocyte counts (relative and absolute) so frequently found in cases of 'irritable heart,' and they do not show any marked increase either in the eosinophils or large mononuclears. In fact, there is nothing in the counts to distinguish these men from other men suffering from 'irritable heart.'" This is in agreement with Dr. G. C. Low's findings in cases infected with intestinal protozoa.^{7, 8}

* The classification used was that given by Cabot in Osler and McCrae's *System of Medicine*, 1915 (see *Lancet*, June 2nd, 1917).

Acknowledgements.

We take this opportunity of recording our indebtedness to Dr. H. H. Dale of the biochemical department of the Medical Research Committee, and to Mr. Clifford Dobell, for very many helpful suggestions and for the practical interest which they have always taken in our work. Dr. Dale arranged for the supply to us of the various forms of emetine bismuth iodide. The methyl-psychotrine used in the treatments here described was kindly furnished, through Dr. Dale, by Dr. F. L. Pyman, Director of the Wellcome Chemical Research Laboratories; while Mr. Dobell has given invaluable assistance with the protozoological examinations, especially by his confirmation of the occurrence of small cysts of *E. histolytica* in the large proportion of carriers mentioned above. The opportunity is very gladly taken of expressing our sincere gratitude to him for his extremely kind and constant interest.

We are indebted to Lieut.-Colonel J. More-Reid, R.A.M.C., Officer Commanding Hampstead Military (Mount Vernon) Hospital, for permission to publish this account of cases in his hospital.

CONCLUSIONS.

1. Additional infections with intestinal protozoa may be detected at the sixth and later examinations.
2. Infections of *E. histolytica* in which no cysts measuring over 10 μ in diameter are found in the stools are far from uncommon.
3. The use of emetine bismuth iodide has cured a large proportion (95 per cent.) of our amoebic dysentery carriers.
4. The best method of administration of this drug is in the form of the loose powder in cachets in daily doses of 3 grains. At least 36 grains should be given in all.
5. Symptoms of irritable heart in amoebic dysentery carriers are reduced in a large number of those patients who have been cured of the amoebic infection.
6. Infection with intestinal protozoa has no marked effect on the differential leucocyte count.

SPONTANEOUS EVACUATION OF A SHRAPNEL BULLET IN THE LUNG BY EXPECTORATION.

BY

R. MURRAY LESLIE, M.A., B.Sc., M.D.,

PHYSICIAN PRINCE OF WALES'S GENERAL HOSPITAL AND ROYAL HOSPITAL FOR DISEASES OF THE CHEST, LONDON; MEDICAL OFFICER BERMONDSEY MILITARY HOSPITAL.

THE main interest of the following case lies in the fact that the bullet was spontaneously expectorated four and a half months after the occurrence of the gunshot wound.

On April 6th, 1916, Pte. P. D., aged 33, while on military service in Mesopotamia, sustained a gunshot wound from a Turkish shrapnel shell. The bullet entered just above the middle of the right clavicle, and there was no exit wound. He stated that he lay unconscious for hours, and that it was ten hours after being wounded before he was picked up. There was no haemoptysis. He was transferred to the base hospital at Basra, where, except for some stiffness and bruising in the region of the right shoulder, he felt fairly comfortable. There was practically no cough nor expectoration. In ten days he was transferred from Basra to Bombay, where he made excellent progress, and the entrance wound, which for a time discharged fairly freely, gradually healed up.

After fourteen days, when the wound was nearly healed, he was shipped to a hospital in Alexandria, where he remained until June 20th, 1916. Three days after landing he developed left-sided pneumonia with pyrexia, cough, and expectoration, pain in the left side of the chest, but no haemoptysis. During convalescence he had a second attack of pneumonia, from which he recovered. He was then sent home to England, and on July 4th, 1916, was admitted to the Bermondsey Military Hospital under my care.

On admission the scar of the entrance wound was visible just above the middle of the right clavicle. His general condition was fairly good, and there was no pyrexia. There was slight cough, with frothy, muco-purulent expectoration, and some pain over the left chest in front, particularly in the third left interspace and through to the back. There was also some dyspnoea on exertion. The pain was not continuous, and was sometimes referred to the left shoulder blade. At the base of the left lung there was marked dullness, with loss of vocal fremitus and breath sounds, due no doubt to thickening of the pleura. At the right base there was also some impairment of percussion.

For the first few weeks the patient was kept in bed, and was then allowed to get up and walk about. His general health improved, the pain in the chest becoming much less severe although some cough and muco-purulent expectoration persisted. In order to assist the expansion of the lungs Woolf's

FIG. 1.—Radiogram taken by Dr. Herbert Rhodes at Lewisham Military Hospital on August 1st, 1916, showing the shrapnel bullet *in situ*, lying behind the left auricle. The broadening of the bullet shadow is no doubt due to the effect of the movement of the heart.

bottles were ordered, and the third day after using these (July 28th, 5.30 p.m.) he had haemoptysis (about 5 oz.), which lasted for two hours. The Woolf's bottles were accordingly discontinued.

On July 29th, the day after the haemoptysis, râles were audible, just below the root of the spine of the left scapula, and persisted for a few days. The patient still complained of slight pain in front over the third left cartilage and also at the root of the spine. The chest was x-rayed on August 1st by Dr. Herbert Rhodes, the radiographer to Lewisham Military Hospital, and the antero-posterior view of the thorax revealed (Fig. 1) the shadow of an object, probably a bullet, in the region of the shadow of the left auricle. A stereoscopic examination showed this to be at a depth of 4½ in. from the level of the skin of the front of the chest. The bullet must thus have traversed the chest obliquely from the root of the neck on the right side, crossing to the left side, and ultimately lodging behind the left auricle. The patient's condition slightly improved, but he still had an occasional cough which aggravated the pain in the left side of the chest. There was still some shortness of breath, aggravated by any exertion. As the condition seemed to remain unchanged he was brought before a medical board and discharged from the hospital on August 16th as unfit for further military service.

As he lived in the north of London he was asked to report at the Prince of Wales's Hospital should occasion arise. On August 21st (five days after leaving the Military Hospital) he presented himself at the hospital with the bullet in his hand. It appears that on August 20th he had had a second haemoptysis followed by a restless night and severe pain between the shoulders, which prevented him from lying on his back, and the cough became unusually troublesome. The following morning (August 21st), on getting out of bed, he was seized with a violent fit of coughing and brought up a piece of lead irregular in shape a little over 1 inch in length, and weighing 140 grains (Fig. 2). He was admitted as an in-patient for further observation, and a second x-ray examination was made on August 25th by Dr. James Metcalfe, when the bullet shadow was found to have disappeared (Fig. 3).

Numerous moist râles were now heard over the posterior aspect of the left chest and axilla, a few râles being also audible over the right base. These râles cleared up in about a fortnight and the patient was discharged comparatively well. He is now enjoying fairly good health with the exception of slight shortness of breath on exertion.

The x-ray examination appeared to show that the bullet lay behind the left auricle in the posterior mediastinum close to the root of the left lung; it no doubt impinged on the left bronchus or one of its main branches, through which it must have ulcerated, and so found its way into

FIG. 3.—Radiogram taken by Dr. Metcalfe at Prince of Wales's General Hospital on August 25th, 1916, with no trace of the bullet shown in Fig. 1.

the lumen of the bronchus, to be ultimately expectorated as above described.

It is open to conjecture whether the blowing into the Woolf's bottles which initiated the first haemoptysis on July 28th may not have partially dislodged the bullet, which was expectorated on August 21st, twenty-four days later, after a second haemoptysis. It is remarkable that the bullet did not lodge for some time in the upper air passages, or was not again sucked by inspiration into the bronchial tubes during the paroxysm of coughing. It is possible that during the night of August 20th the bullet may have lain partially projecting through the torn bronchus during the twelve or more hours' clapping between the haemoptysis at 5.30 p.m. on the 20th and the expectoration of the bullet as the patient was getting up on the morning of the 21st. The troublesome cough, the restlessness, and the severe pain in the chest during the night suggest the probability of such being the case, and the final expulsion was no doubt due to the severity of the paroxysm of coughing. Had the bullet lodged permanently in the upper air passages, it would

FIG. 2.—Representation of dislodged bullet or piece of lead from Turkish shrapnel shell coughed up by patient on August 21st, 1916. (Actual size.)

have been necessary to have had it extracted by aid of the bronchoscope. The sharp edges and the elongated form of the piece of shrapnel no doubt contributed to the bronchial perforation and consequent evacuation of the bullet. I know of no similar case of spontaneous evacuation of an ordinary smooth conical rifle bullet.

A BED has been endowed in the Leicester Royal Infirmary by a gift of £1,000 in memory of Mr. John Platts, of the firm of Southall Brothers and Barclay, wholesale chemists, Birmingham.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

BRONCHIAL ASTHMA.

More than forty years ago, in conjunction with my father, I treated asthma amongst the miners of the county of Durham. It was common in those days when the ventilation of the mines was much worse than the conditions now prevailing.

Having had the privilege of acting as a deputy physician to out-patients at the City of London Hospital for Diseases of the Chest, Victoria Park, E., for the last eighteen months, I have been brought into contact with asthma as witnessed amongst those who work with furs, or follow dusty occupations, or more probably live in small, badly-ventilated rooms.

From notes of 94 cases, I find that in 25 per cent. the condition is hereditary; that it afflicts all ages, from 6 or 8 years of age to 60; that certain seasons aggravate the complaint, whether this be due to the humidity of the atmosphere or a fall in the barometer. Dry frosty weather agrees best with most asthmatics. Any indiscretion in diet is certain to be followed by a night of asthma; and here we notice the analogy between asthma and epilepsy. In each case it is a madness of the nerves; in bronchial asthma it is the pneumogastric nerve that is at fault. In each complaint an error in diet aggravates the trouble. Sometimes premonitory symptoms or warnings are recorded in epilepsy and asthma. With asthma there may be a tickling or stuffiness of the nose just previous to the attack.

An asthmatic patient feels well for three or four weeks and then may be laid low for a whole week; this resembles the story given by the epileptic. Most asthmatics have constipation, and the same condition aggravates the lot of the epileptic. Bromides relieve the epileptics, whilst iodides do much good to the asthmatics. As described by many authors, the asthmatic has not only his struggle to breathe, but he has a violent cough which continues until he can bring up a pellet of mucus, and then he finds relief and may get some sleep. For the severe attacks of asthma a preparation "Grindelene" does good. It contains *grindelia*, potassium iodide, liq. trinitrin., and tincture of *Euphorbia piliifera* (Oppenheim). For chronic conditions of asthma which generally came before me, when the patient is seldom free from the wheezing and contraction of the chest, nothing does so much good as a combination of potassium iodide and magnesium sulphate, 5 grains of the former and 1 drachm of the latter, in an ounce of water, taken three times a day, two hours after a meal. The preparation of this combination requires consideration; it is necessary first to dissolve the magnesium sulphate in hot water before adding the potassium iodide. If the two salts are mixed without this precaution a solid mass will result. I prescribed the preparation for all the cases which came under my care. If a toxin exists in asthma, as some assert, then the iodide will destroy that toxin. It will cause also a flux or flow of watery mucus from the bronchial tubes, much to the relief of the patient. The magnesium sulphate removes any constipation that may exist, and, acting upon the first part of the intestinal tract, washes away any effete matters which may offend. In addition to the drug treatment I always gave strict injunctions as to diet, and generally provided a printed form for the guidance of the patient.

Ruislip, Middlesex.

EDWARD JEPSON, M.D.

BASOPHILIA IN THE DIAGNOSIS OF LEAD POISONING.

SOME years ago I convinced myself that the presence of punctate basophilia was a valuable help in the diagnosis of lead poisoning, as several writers had insisted. By treating eight suitable cases—diarrhoea, haemorrhage, etc.—with lead acetate, after the manner of an older generation, I found that in seven punctate basophilia appeared on the third to the seventh day of treatment. In a case of uterine haemorrhage it did not appear during a fortnight's treatment. Recently I was consulted in the case of a painter who believed himself to be suffering from lead colic. The result of a careful examination was negative, but my view was not accepted. Later I was consulted again. I had examined the patient's blood without finding basophilia.

I was aware that this did not exclude lead, but it occurred to me that, if I carefully examined the blood again without finding a trace, I might quite safely give him a few doses of lead and watch the result. On the fourth day punctate basophilia was distinctly observed, and the medicine immediately stopped without any bad result whatever. The inference appears to me to be quite legitimate that the man's blood reacted in a normal manner to lead, and that the previous absence of basophilia might be accepted as evidence against lead poisoning.

Ealing.

ROBERT CRAIK.

Reports of Societies.

VALUE AND LIMITATIONS OF SANATORIUM TREATMENT FOR TUBERCULOSIS.

At a meeting of the Medical Society of London on November 12th, the President, Sir ST. CLAIR THOMSON, being in the chair, a discussion was opened on this subject, and adjourned to Monday next.

INTRODUCTION.

Dr. T. D. LISTER said that according to the annual report for 1916-17 of the medical officer of the Local Government Board, the deaths from pulmonary tuberculosis had increased 12 per cent. since 1913, the mortality depending on environment rather than on infection. Since 1911 the number of beds available for the treatment of tuberculosis had doubled, and tuberculosis dispensaries had increased over twelve-fold. He disagreed with the statement made in the report that measures for the treatment and prevention of tuberculosis were, to a large extent, identical. He had seen better results from sanatorium treatment in certain bad cases when they had come from the industrial group than in certain good cases coming from a higher social class. The industrial patient sometimes got a better chance because he got a bigger change. Sanatorium treatment could not be carried out in the majority of homes. Too much might sometimes be claimed as the result of the institutional training, and the lessons learnt were, more often than not, largely forgotten after leaving. He thought that efficient treatment at home was more expensive than that at a sanatorium. The after-history depended largely upon opportunity. Few patients would or could change their environment afterwards. He asked whether the value of the sanatorium method was increased by using any of the derivatives of the tubercle bacillus, and if so, what were its uses in the many cases of mixed infection and the relatively few cases in which a pure infection could reasonably be inferred? The association with tuberculin of vaccines for mixed infection was difficult, costly, and complicated. Such methods were better carried out in sanatoriums under full control, but were only adapted for a very small proportion of the total mass of cases in institutions, so that the value of sanatorium treatment could be little affected by them. The carefully planned scale of diet of the sanatorium, with general attention to digestion, rest and exercise adjusted to meal times, might in some proportion of patients be sufficient to turn the scale in the right direction, but there were some in whom improved nutrition and consequent formation of immunizing bodies was impossible because of an original fault in their biochemistry. The manner in which a family resisted or succumbed to tuberculosis was of great importance in prognosis; diet was often a matter of family tradition, and a type of biochemistry was readily inherited. The results attained by those who gave much or little medicine by mouth or in other ways did not seem to differ greatly. Creosote was still variously used. Nascent iodine treatment did not seem to give all the results hoped for, and latent syphilis should be excluded before ascribing any improvement to the effect of this method on tubercle. The gradual fall of the total death-rate was, he thought, due to the creation of a race resistant to tuberculosis by the ruthless methods of nature, and if nature was to be assisted there was perhaps more to be said for prophylactic inoculation than for increased institutional treatment. The real value of the sanatorium was that it demonstrated how resistance was regained, and inferentially, therefore,

how it was previously lost. What was needed was better domiciliary treatment, and a larger number of skilled supervisors.

THE WELL-TO-DO.

Dr. DAVID LAWSON said that the well-to-do patient usually came under treatment while the disease was in its early phase; he was free to absent himself from home for whatever length of time was necessary, and he was free from anxiety on account of those whom he had left at home; it was therefore reasonable to expect that the results of sanatorium treatment of this type of patient would be more favourable than those obtained where the cardinal element of prolonged treatment had not been available. Sanatorium treatment, as it was now understood and administered, secured for the patient, under special climatic surroundings and under conditions specially favourable for detailed supervision, all the resources of modern medicine. He gave records of 1,000 cases of pulmonary tuberculosis which had passed through his hands in recent years, these including a small number of cases of pleurisy presumed to be tuberculous. The patient's condition was considered as it appeared to be on the point of leaving the sanatorium. He divided them into three categories: (1) Those whose state had *depreciated*—that is, (a) those who had died in the sanatorium, and (b) those designated "worse," in whom the disease appeared to be inexorably advancing; (2) those who were *improving*; (3) the *appreciated* class, including cases of arrest or complete recovery. Under complete recovery were included those patients whose expectoration had either disappeared or contained no tubercle bacilli, and in whose chests no evidence of moisture could be detected; by arrest was meant a similar condition, except that (a) there might still be a little expectoration from time to time containing tubercle bacilli, and (b) a little moisture in the lung might still be recognizable.

TABLE I.—Analysis of 1,000 Cases of Pulmonary Tuberculosis treated under Sanatorium Conditions.

TABLE VI.—Senile Phthisis.

(Occurring after 50 years of age.)

Depreciated, 22=38.6%.		Improving, 17=29.8%.	Appreciated, 18=31.6%.	
Worse, 15=26.3%.	Died, 7=12.3%.		Arrest, 7=12.3%.	Complete recovery, 11=19.3%.

Sex incidence: Male, 49; Female, 8.

Age incidence: Under 60 years, 47; 60 years and over, 10.

Regarding the bearing of a parental history of pulmonary tuberculosis on the results of treatment, he said that in 112 instances one parent had suffered from pulmonary tuberculosis. In only 10 instances had both parents been tuberculous. This fact seemed strangely at variance with the popular impression that heredity exerted a determining factor upon the incidence of pulmonary phthisis.

He then considered to what extent the patient's own clinical history of certain maladies tended to limit or affect the result of treatment.

Syphilis occurred in 8 cases, and did not appear to be necessarily a serious element in regard to prognosis.

Malaria occurred in 33 cases, of whom 8 died, 9 occupied an intermediate position and improved, and of the remaining 16, all of whom did well, 9 made complete recoveries, and in 7 the disease became arrested. These figures would appear to indicate that this disease should be more seriously regarded in endeavouring to form a prognosis than had usually been the case with many in the past.

Appendectomy had been performed previously on 51 patients, or over 5 per cent. of the total number. Of these, 11.21 per cent. depreciated, 6.11 improved, and 66.6 per cent. appreciated.

Pleurisy occurred as an antecedent in 114 cases, and in a large majority had been present at the base upon the same side as that on which the apical disease appeared at a later date. That it was the commonest of all precursors of pulmonary tuberculosis suggested the desirability of prolonged after-treatment where the disease appeared in youth.

He then spoke of the extent to which certain complications limited the effect of sanatorium treatment.

Glycosuria.—Five cases have been observed, of which one died, one made a complete recovery, and three appeared to be improving when they left the sanatorium.

Ischio-rectal abscess had not proved to be a common complication, and in the series now under review occurred in only 2.3 per cent.

Meningitis.—The great rarity and extreme gravity of this complication of pulmonary tuberculosis in the adult was evidenced by the fact that it occurred in only four cases, but in all proved rapidly fatal.

Laryngeal disease was a grave complication. The number treated was 47, or 4.7 per cent. of the whole, and of these 48.8 per cent. did badly, 25.5 per cent. improved, and 27.6 per cent. appreciated, of whom 6.12 completely recovered. Except as a palliative recourse undertaken to alleviate suffering he had not been favourably impressed by the results which had followed surgical interference. Partial or complete rest of the organ continued to be the most effectual weapon in combating this complication.

Senile Phthisis.—There were 57 cases of senile phthisis—that is, occurring in patients over 50 years of age. In only 10 instances was the onset of the disease delayed beyond the sixtieth year. Depreciation took place in the condition of 22 patients, of whom 7 died; appreciation occurred in 18, of whom 11 made complete recoveries; the remaining 17 improved. From those figures it appeared that pulmonary tuberculosis occurring in later life was both more common and more serious in regard to the prognosis attaching to it than many had thought. He felt convinced that routine examination of sputum for tubercle bacilli in all cases of recurring winter cough and subacute and chronic bronchitis occurring in patients over 45 years of age should be more widely adopted in general practice than at present appeared to be the case.

Diet.

With regard to diet, he disapproved of excessive super-alimentation, and based the dieting at Banchory upon the conclusions arrived at as the result of the investigations on the metabolism of phthisis carried out by Drs. Bardswell and Chapman and Dr. Goodbody. When a patient had reached the vicinity of his top weight dyspepsia was apt to set in, and this should be taken as an indication for making a permanent reduction in the amount of food given.

With regard to alcohol he dispensed with its use, except for patients of 50 years and upwards who had accustomed themselves to a nightcap of this kind and who slept better if the practice was not interfered with. In some of the more marked cases of anaemia red wines seemed to be of true value. As a temporary change from milk, when

recurring bilious attacks were causing trouble, beer or whisky and soda were useful, but the milk in the diet ought to be resumed at the earliest possible opportunity.

Recreations.

In order to induce patients to prolong their residence under sanatorium conditions by relieving the monotony of the life, he decided to try the effect of employing mild outdoor games as a form of exercise. In 1904 a short 6-hole golf putting course was laid out within the sanatorium grounds. That the change was on right lines very soon became apparent. Its application had therefore been steadily extended. With its extension it was observed that the depression and morbid introspection began to disappear, the tone of the patients steadily improved, until at length it reached and had been maintained at a level which, alike from the doctors' and patients' point of view, left nothing to be desired.

In selecting the particular form of sport which might be prescribed, the following restrictions ought to be observed:

(a) It should not be possible for the patients to exhaust themselves in following it. For this reason such sports as these should be barred: hockey, football, lacrosse, fives, tennis, hunting, dancing, long-distance running, boat racing.

(b) The risk of mechanical strain with consequent rupture of an imperfectly healed lesion should be avoided. On that account these sports ought to be barred during the term of treatment and for a minimum of one year after recovery has taken place.

He was absolutely convinced that resumption of full golf ought to be strictly discontinued within twelve months of complete recovery having taken place.

Shooting seemed quite suitable if the patient was content to confine himself to a moderate amount of walking, but he should be warned against firing at the bird which was disappearing quickly over his head, as the sudden upward movement of the arms required involved all the risks of mechanical strain in the region of the apices of the lungs.

Swimming.—Provided the powers to reaction as shown in the circulation were good, he had seen nothing but benefit result from this form of exercise.

Tobogganing was permissible, and also skating if carefully regulated, but bobsleighting, because of the chest compression, involved unwarrantable risks of inducing a breakdown through mechanical strain.

Alluding to special forms of treatment, he said that only on the rarest possible occasion had he seen tuberculin inoculation, when administered during the pyrexial phase of the illness, followed by any benefit. The most useful role of tuberculin was to employ it when, a large measure of arrest having already been attained, the patient's progress appeared to have come to a standstill. Reserved until this stage its exhibition was then frequently followed by a fresh start being given and the patient renewing his progress towards recovery.

Artificial pneumothorax was by far the most valuable addition to the armamentarium of the sanatorium physician which had been made in our generation. He had found it of the greatest possible value in two conditions: (a) as a means of stopping hæmorrhage which was present on a dangerous scale, and (b) in bringing about arrest in localized acute disease. In regard to cases of widespread dry pleurisy, although he had separated the pleural surfaces in such cases, he was still in doubt as to the value of the operation in this connexion.

THE MIDDLE CLASSES.

Dr. NOEL BARDSWELL said that the patients at the Midhurst sanatorium included clerks, school teachers, shop assistants, commercial travellers, civil servants, and members of the various professions. The average length of treatment in the sanatorium was four to five months. He gave statistics concerning 384 cases observed over six years following their discharge, in which the number of deaths which occurred among patients of various ages—termed the "actual deaths"—was compared with the number of deaths which would have occurred had these same patients been members of the general population—termed the "expected deaths." The cases were divided into two groups—Group I including those in which one lobe was involved, and Group II those in which more than one lobe was involved, with slight constitutional disturbance as well. Tubercle bacilli were present in the sputa of all these

patients. The record showed that during a period of six years following discharge from the sanatorium the number of deaths which occurred among Group I (101 cases) was over six times, and among Group II (283 cases) over twenty times that of the expected deaths. Taking the experience of the 384 cases, the actual deaths during the period of observation were more than sixteen times as many as the expected number. When observations were extended over a longer period of years the disparity between actual and expected deaths became less marked, as the worst cases succumbed during the first few years after discharge. A similar study of the after-histories of 1,449 cases treated at the Adirondack Sanatorium, U.S.A., published by Lawrason Brown and Pope, showed almost identical results. He thought after-care was of supreme importance. Among those who had done well a large proportion had been enabled to continue their treatment for some months after leaving the sanatorium. The nature of the employment followed had a great bearing upon prognosis. The most encouraging results appeared among those who were able to exchange unfavourable for favourable conditions of work. Removal to country districts was of the greatest advantage, and, where this was impossible, a shortening of the hours of work or a long week-end for some months after discharge had proved of much value. He wished to emphasize the point that the critical time began when the sanatorium was left. Success or failure was determined during the next two or three years. It was the patient himself and the general practitioner who then shouldered the responsibility, and but for their full appreciation of the position and ready co-operation much of the work of the sanatorium would be lost. More than once he had discussed the question of sanatorium treatment with some of the senior members of the profession, and their opinion agreed with his own, that the sanatorium movement had influenced profoundly for good the outlook for the consumptive. His experience was that, however favourable the home conditions might be, a short term of practical instruction in a sanatorium was of much assistance both to the patient and his medical attendant. He agreed that statistics should be approached with doubt, but to be able to state whether a patient were alive or dead six or seven years after discharge was to possess data of real value. The after-history results at Midhurst for the three consecutive years during which tuberculin was employed largely were no better than those for any three years during which it was not used at all—nor were they any worse. The same could be said for vaccine treatment of mixed infections.

THE WORKING CLASSES.

Dr. WILFRID O. MEER said that the results of sanatorium treatment of the working classes, as revealed by the after-histories, were at present far from satisfying. During the three years 1905-6-7, 292 patients, in whose sputa tubercle bacilli had been found, were discharged from the sanatorium at Frimley. Of 266 of these who were traced to the end of the first year following that of their discharge, 65.8 per cent. were well and working, 24.4 per cent. were alive, and 9.8 per cent. were dead. Of 245 traced to the end of the second year following that of discharge, 56.8 per cent. were well and working, 21.6 per cent. were alive, and 21.6 were dead. Of 209 similarly traced to the end of the fifth year following that of discharge, 38.8 per cent. were well and at work, 14.8 per cent. were alive, and 46.6 per cent. were dead.

He then considered some of the chief factors responsible for such a rapid loss of working capacity in so high a proportion.

1. *The Return to Faulty Environment*.—The great majority of these 292 individuals returned to their work in London at which they had broken down previously. Statistics were given illustrating the rapid wastage on return to urban industrial life, and the improved outlook under better conditions. As shown in the case of the patients who had been able to secure a change for the better in their work and surroundings, obvious alternatives were: (a) Greatly prolonged residence in sanatoriums; (b) a long or short period of treatment, respectively combined with or followed by training and subsequent start in suitable work in a proper environment; (c) the establishment of rural industrial centres, in which patients could work at their accustomed or some closely allied branch of industry.

2. *The lack of provision for prolonged treatment*, the working man, who is obliged to return to full work immediately upon his discharge, requiring longer sanatorium treatment than any other class.

3. *Lack of Provision for Re-treatment*.—If loss of health or recrudescence of symptoms pointed to a probability of relapse, prompt cessation of work and removal to a healthy environment were called for. Improvement was most rapid and satisfactory under sanatorium supervision, but admission, as a rule, involved a long period of waiting.

4. *The admission of cases unsuitable on grounds other than medical*, such as habits, lack of will power and intelligence.

5. *The Need for Earlier Diagnosis*.—In a disquieting proportion of the patients reaching sanatoriums for the first time permanently crippled by extensive disease there was a previous history of initial symptoms disregarded or made light of. Since treatment of advanced active disease was so hopeless, and since in even selected cases of manifest disease present methods called for elaborate and costly amplification, recognition of initial symptoms and supervision at the really incipient stage were all-important for the working man. Given certain essentials—namely, early diagnosis, reasonable treatment, and a chance to spend his future working life in a proper environment—certain attributes of this class of patient made him the most profitable subject for sanatorium treatment.

Captain H. MORRISTON DAVIES said that the mechanical disabilities, which appeared almost from the earliest stage, gave rise in chronic cases to symptoms more serious even than the primary disease. They were due, on the one hand, to the fibrous tissue formation in the lung and in the pleural membranes, and, on the other, to the anatomical and physical conditions of the lung, of the pleural cavity, and of the surrounding walls. At first, contraction of the lung, due to the fibrosis, could to a great extent be equalized by the falling in of the chest wall, by the displacement of the mediastinum and diaphragm, and by emphysema of the healthy parts of the lungs. Once this stage was past, and with the increase of the fibrosis, of the bronchial dilatation and secondary infection, and the development possibly of cavities, a temporary improvement only could be hoped for, unless the mechanical disabilities were compensated by surgical interference. The four methods available were:

1. Nitrogen displacement, with stretching, division, and even rupture of adhesions when necessary.

2. Partial replacement of the lung and parietal pleura by foreign substances when the disease was localized and nitrogen displacement impracticable owing to pleural adhesions.

3. Rib mobilization, by which operation the lung, together with the chest wall, were collapsed; this was a more serious operation than nitrogen displacement and therefore suitable only when the latter was impossible.

4. Paralysis of the diaphragm by section of the phrenic nerve in the neck. The affected half of the muscle was relaxed, and rose into the thorax. The symptoms due to distortion of the diaphragm owing to basal adhesions or to the drag on the muscle during nitrogen displacement were abolished. There was a reduction in the size of the lower part of the pleural cavity, and a partial collapse of the base of the lungs. This was of great benefit in cases of tuberculosis or of dilatation, whether primary or secondary, of the bronchial tubes of the lower lobe.

Surgical intervention must not be regarded as a method of treatment which could be carried out independently of the medical. The best results were obtained by the closest combination of the two.

If the type of case was rigidly selected, the results obtained were extremely gratifying.

All these methods produced a general or local collapse of the lung. They allowed the fibrous tissue to contract without causing distortion of the intra-pulmonary and extra-pulmonary structures. Interstitial and bronchial cavities were obliterated and the serious effects of secondary infections were abolished. The lung was at rest and the symptoms subsided. The patient was thus placed in a condition in which medical and hygienic treatment could be employed with most beneficial results.

THE USE OF NITROUS OXIDE AND OXYGEN WITH REBREATHING IN MILITARY SURGERY.

At a meeting of the Medical Society of London on October 29th, the President, Sir ST. CLAIR THOMSON in the chair, Captain H. EDMUND G. BOYLE, R.A.M.C.(T.), read a paper on experiences in the use of nitrous oxide and oxygen with regulated rebreathing in military surgery at the 1st London General Hospital.

INTRODUCTION.

Captain Boyle said that with this method induction was easy, and recovery rapid and comfortable.

Method of Induction.

Half an hour before the operation the patients were given a preliminary injection of morphine tartrate $\frac{1}{4}$ gr., atropine sulphate $\frac{1}{100}$ gr., scopolamine $\frac{1}{100}$ gr., made up so that 5 minims was the dose. One drop of pure carbolic was added to 4 oz. of the mixture as a preservative. The apparatus used was Gwathmey's,¹ and consisted of four cylinders, two for nitrous oxide and two for oxygen. The supply of each was controlled by two graduated taps, which permitted the gases to flow through the glass bottle containing water in a proportion which could be seen, so that there was visual evidence of how much of each gas was being inhaled by the patient. The gases might go direct to the patient by way of the rebreathing bag, or might be directed through a bottle containing either ether, or chloroform and ether, or such mixture as the administrator chose. The facepiece had at its top a valve to permit a certain amount of intake and output of air and mixed gases. During induction the room should be absolutely quiet, and he preferred to have the head slightly raised until anaesthesia was complete, when he lowered it to the horizontal. He frequently inserted a small dental prop before starting, and always did so when the patient did not breathe easily through the nose and when the nose was narrow with very thin alae nasi. The thin alae were drawn in towards the septum and the patient made violent efforts to breathe but got next to nothing into his lungs. He then became pale, with a bluish tint round the mouth. The pupils dilated and sweating came on. The treatment was to open the mouth and get air and oxygen into the lungs.

At first the bag was filled with nitrous oxide and oxygen in the proportion of 4 to 1, rebreathing starting almost from the beginning. The supply of nitrous oxide was then increased until flowing freely, in order to lessen the period of induction. In about three to four minutes the patient's breathing took on that automatic character which was such a constant sign of anaesthesia. Any degree of cyanosis must be remedied by the addition of a little oxygen, very little being needed to change the colour back to pink. As soon as anaesthesia had been attained the amount of nitrous oxide was reduced to 4, the oxygen being at 1. With this rate most patients would go on perfectly well, and rebreathing could be continued most of the time. Retching or vomiting indicated that there was too much rebreathing, and the valve of the facepiece should be opened and the supply of nitrous oxide and oxygen increased. To deepen the anaesthesia the pressure in the bag should be increased until, when an expiration took place, the bag became taut. The signs of overdosage were noisy and stertorous breathing, followed by twitchings of the muscles, and accompanied by cyanosis. The remedy was more oxygen. The importance of an open and free airway should never be forgotten.

It sometimes became necessary to add either ether or C.E. mixture to the gas and oxygen when extra relaxation of the muscles was required, or during amputations when the nerves were being severed, or occasionally if there was a little difficulty during induction in obtaining anaesthesia. Up to the present he had only added chloroform in the case of a burly or alcoholic patient who needed something more potent than ether alone.

Regulation of Rebreathing.

With regard to regulation of rebreathing he agreed with Gwathmey, who said that approximately the rate of flow of the gases should be such that from a quarter to a half

¹ See his paper, BRITISH MEDICAL JOURNAL, 1917, vol. 1, p. 393.

of the volume of each respiration was of freshly added gas mixture. Too much rebreathing was apt to be followed by post operative discomfort, usually headache, and it might cause an increase of post-operative nausea and vomiting. Vomiting during the progress of the anaesthesia was often an indication of excessive rebreathing for that particular patient, although in comparison with other patients it might not appear excessive. With regulated rebreathing the profuse sweatings and exhaustion noticed after prolonged nitrous oxide and oxygen alone did not occur. The patients retained a good colour, their temperature was, if anything, slightly raised, and there should be no sweating.

Symptoms of Overdose.

The symptoms of an overdose of nitrous oxide in the presence of sufficient oxygen to keep the patient pink were, first, stertorous respiration, and, secondly, the onset of an excessive secretion of mucus. Unless the percentage of nitrous oxide were then decreased the patient's face and hands took on a death-like pallor (not cyanotic); there was absolute loss of all the facial reflexes; the respirations became shallow, and probably the blood pressure fell. This condition, if pushed, would probably lead to death from paralysis of the respiratory centre. The treatment was rapidly to remove the mask and start artificial respiration and to administer oxygen, remembering always to keep the airway clear.

After-condition of Patient.

The post-operative condition was striking. The patients were conscious within two or three minutes of the removal of the anaesthetic, and, in the majority of cases, were not sick. There was in a fair proportion a feeling of nausea, lasting about twenty minutes, and occasionally there was some headache, which was probably due to too much rebreathing for the particular patient, but beyond that the recovery was perfect. There was no taste of ether in the mouth, and no waves of ether vapour coming over as the patient eliminated the drug, even if a little ether had been given during the early stages of the anaesthetic. Since both gases were non-toxic, the combination was especially suited to the badly wounded and septic man. In most of 200 consecutive cases at the 1st London General Hospital there was no appreciable rise of temperature after the operation. Of 711 cases in which this combination was used, 5 had had bronchitis, one of whom had slight bronchopneumonia. There were no fatal cases. Of 550 administrations by Captain Boyle alone, 38 per cent. had either ether or C.E. mixture (two had chloroform alone).

Contraindications.

He considered the method unsuitable (1) for operations in which absolute relaxation was required all the time; (2) some abdominal cases—for example, gall bladder operations. These could be done, but unless the surgeon was prepared to make a large incision and to inject the muscles with some analgesic mixture the operative procedure would be very difficult. It was possible to do appendix operations if the surgeon were going through the muscles over McBurney's point, but if he preferred to go behind the rectus, unless there was to be an injection of the muscles, the gas and oxygen method was not, from the point of view of the surgeon's comfort, to be advised.

Conclusion.

The average amount of the gases required under ordinary consumption was 200 gallons of nitrous oxide and 60 gallons of oxygen for two and a half hours. The work of the nurses was considerably lessened when this combination was employed, as a conscious patient who was not vomiting did not require the undivided attention of a skilled nurse. This was of great importance in a large military hospital where eight or ten operations might be all from the same ward during a morning's work. This combination of anaesthetics was not one to place in the hands of the careless or inexperienced. It required skilful administration, and if used carelessly would inevitably lead to disasters.

DISCUSSION.

Colonel D'ARCY POWER confirmed all Captain Boyle had said from the surgeon's point of view. Unless care were taken the patient was likely to come out of the anaesthetic, as the anaesthesia was on the light side.

Dr. DUDLEY BUXTON said that before using the method much care and experience were necessary, and he emphasized the importance of rebreathing. There were two schools: one held that there was always some cyanosis, the other that cyanosis was dangerous and should be avoided. He agreed with the latter, and considered that cyanosis was not a necessary accompaniment of anaesthesia; cyanosed cases were always worse afterwards. He thought it better to give the alkaloids an hour before the operation, and laid stress on the importance of silence during induction, for which there should be a separate room.

Mr. HERBERT PATERSON said that one drawback to the method was that when gas and oxygen were given for abdominal operations patients suffered severe pain for about twelve hours afterwards. He thought the reason was that the intestine was not paralysed, as after ether and chloroform, so that peristalsis continued for longer; but morphine could be given as it could not be after the latter anaesthetics. One of the greatest advantages was the absence of nausea, which lasted about three days after the administration of ether. With regard to the very slight post-operative rise of temperature, he said that after clean operations performed under aseptic conditions some rise of temperature was regarded as usual, but he had found that the average post-operative rise of temperature with gas and oxygen was one degree less than in similar operations in London performed under gas and ether. He showed temperature charts of patients operated on for appendicitis and hernia, illustrating the difference in temperature in those who had gas and oxygen and those who had chloroform and ether. In the former the highest temperature was 99° F., whereas in the latter it usually rose to about 100° F. In some cases in which gas and oxygen had been given there was no rise of temperature at all. The gas and oxygen method in experienced hands was incomparably better than chloroform and ether. Gas and oxygen were first given for long operations in 1895, but since then the technique had been much improved. The late Sir Frederick Hewitt and Mr. Bellamy Gardner used it in 1895, and it was rediscovered in America in 1897. He considered it most difficult to give; six months' or even a year's experience was needed before it could be given satisfactorily from the surgeon's point of view. It might make the operation more difficult to do, but the patient was safer and was more comfortable afterwards, and fatalities were less frequent.

Colonel H. J. WARING said that, owing to the shortness of induction, much of the surgeon's time was saved. The following classes of case were suitable for gas and oxygen: (1) Septic cases and patients requiring severe operations; (2) operations on patients who were extremely ill, as there was very little shock; (3) operations on old people, as there was not the same danger of bronchitis. The method was not suitable for muscle splitting operations, such as operations on the gall bladder, but was good for operations for enlarged prostate and septic operations. He thought that the small amount of suffering by the patient was a very important point, and gave instances illustrating very quick recovery.

Mr. J. H. CHALDECOTT said that his experience of gas and oxygen dated from the publication of Crile's paper in this country. It was then used combined with local anaesthesia, and he had so used it at St. Mary's Hospital for abdominal operations. He considered it good combined with local anaesthesia; the gas and oxygen provided unconsciousness; the local anaesthetic provided anaesthesia. He never gave gas and oxygen alone for gall-bladder operations, but combined with novocain it was excellent, and there was no after-trouble. Referring to the management of cases, he said that (1) a good airway should be ensured before starting; (2) there should be silence during the induction and during anaesthesia; and (3) the anaesthetic should be continued until the patient was on the trolley and not stopped while he was still on the operating table or he would come round. It was important that the patient should be placed in position for operation before induction.

Major McADAM ECCLES, who said that patients complained of the tooth-prop, asked for information as to the relative cost of the method as compared with ether and chloroform. The weight of the apparatus would make it inconvenient for use in many instances, such as for operations performed in private houses. Owing to the quantity

required, gas might run out in the middle of the operation. He attributed the after-pains to the intestine not being paralysed and peristalsis still going on; the pain was relieved by placing rubber hot-water bottles on the abdomen. He insisted on the need for quiet before induction, and thought the alkaloids were important in this connexion. The patient should never be touched during induction by any one but the anaesthetist, and should be placed, for preference, on the operating table before induction. The rapidity of induction allowed this without loss of time to the surgeon.

Dr. SHIRWAY said that rebreathing introduced a new factor—namely, CO_2 —which acted as a stimulant to the respiratory centre, and therefore produced a different type of anaesthesia. With an increase of CO_2 in the bag and a diminution of oxygen the heart, already starved of oxygen, was being stimulated and would easily become dilated. In America a good many deaths were known to have occurred under gas and oxygen. He suggested that the percentage of CO_2 in the bag should be worked out. He attributed vomiting during and after anaesthesia to stimulation of medullary centres by CO_2 , and thought the amount of CO_2 should be reduced as much as possible. There was urgent necessity for research in anaesthesia—both scientific and physiological—and money was needed to carry it out.

Mr. HUGH LETT expressed the opinion that gases should be heated; the administration of unheated gases might be the cause of bronchitis.

Mr. BELLAMY GARDNER said that there was great danger in trying to rely solely on gas and oxygen. When vomiting occurred during anaesthesia it was not possible to overcome the consequent closing of the air passages by narcotizing the vomiting centre further, as could be done by ether and chloroform. He thought the advantages of the method were not compensated for by the disadvantages of which the patient was ignorant.

Dr. HUGH PHILLIPS said the effect of gas and oxygen combined with local anaesthesia depended upon the method of local anaesthesia employed. If complete in all layers, the result was very good. Silence was of more importance in this method than in any other; the patient should be placed on the table some time before induction was begun. The disadvantages of the method were the weight of the apparatus and the expense. The cost of gas and oxygen and sufficient ether was about 10s. to 12s. an hour.

The PRESIDENT noted the remarkable absence of shock after some operations—for example, in resection of the septum and in laryngo-fissure, the latter requiring a good deal of manipulation. He accounted for it by the fact that a local anaesthetic was always used.

Captain BOYLE said, in reply, that the amount of experience needed depended entirely upon the person. Some learnt the method very quickly. He thought the cost was about 7s. 6d. an hour. The apparatus weighed about 65 lb. There was no need to heat the gas, as it was heated by the patient's breathing. If the gas ran out, it was easy to pass the oxygen through the ether and give that combination for the remainder of the operation.

Rebrielus.

A TEACHER'S TEXTBOOK OF MIDWIFERY.

TEN senior and junior teachers of obstetrics in London, representing between them eight general hospitals and three large lying-in hospitals, have united under the general guidance of Dr. COMYNs BERKELEY in a textbook of *Midwifery*.¹ Primarily designed for students, it is calculated also to be useful to practitioners.

The authorship is sufficient guarantee that the teaching contained in the book is sound. Generally speaking, it reflects thoroughly modern views with sufficient conservatism to act as a corrective to any extreme tendencies. But the main interest of the book lies in the system of collaboration by which it was written. In the case of textbooks of midwifery the chief difference between one book and another lies in the method of presentation of the

subject. The bulk of the subject matter is much the same in them all, but in the method of presenting it the author's individuality gets a chance to show itself, and thereby the book is probably either made or marred.

In the case of this textbook the editor states that efforts have been made to overcome the defects of collective authorship. The manuscript of each author was circulated amongst the other nine and numerous meetings were held at which the various portions of the work were criticized and amended and, if need be, rewritten "so as to include, as far as can be, the views of all."

The result of this treatment has admittedly been to remove the common glaring faults of collective authorship. But it has done more. It has made the writing almost entirely devoid of individuality and rendered it rather dull reading for students. Here and there flashes of individuality appear to emphasize the general greyiness. Such, for example, is the section upon the scopolamine-morphine combination—a brief, trenchant, and sound discussion of the subject, tinged with the saving grace of humour that is so conspicuously absent from the lay articles on that topic.

Apart from these faults of design, the book gives a full and able account of its subject, and the practical teaching bears, as one would expect, the hall-mark of wide and active experience. The illustrations are good, and in most instances helpful. It seems rather a waste to expend almost a page of the chapter on eclampsia upon an illustration of such a non-essential feature as dilatation of the ureters. There are also one or two minor mistakes, such as Fig. 303, where the block has been placed upside down. The paper and printing are excellent. We congratulate the editors on a high degree of success in a difficult venture.

PSYCHOLOGICAL MEDICINE.

THE third edition of Dr. MAURICE CRAIG's successful book on *Psychological Medicine*² contains a new chapter on the functional neuroses and psychoneuroses which have become so prominent since the outbreak of war. A wise caution is thrown out not to regard as malingering the manifestations of war shock unless obviously so proved, for this old view is true in but few cases and should then be easily detected. While hypnotic suggestion is admitted to have been beneficial in some of the cases, the results of psycho-analysis have not impressed the author favourably. In the well-illustrated account of general paralysis of the insane some reference might have been made to Noguchi's demonstration of the presence of spirochaetes in the substance of the brain, which has made the term central or parenchymatous syphilis preferable to the more familiar "parasyphilis," and to the conception that the clinical manifestations of "parasyphilis" are an expression of the reaction and necrosis of hypersensitized areas of the nervous system evoked by the reappearance of the *Spirochaeta pallida* (McIntosh, Fildes, Head, and Fearnside). The Mental Deficiency Act of 1913 is fully referred to.

In the general section on treatment a fuller account is now given of psycho-analysis, which, while recognized as a valuable method of investigation that has explained the origin of certain nervous symptoms, is regarded, even apart from its objectionable character, as a method of treatment attended by no small dangers. In conclusion, the common sense, clinical insight, and practical advice on treatment should thoroughly recommend this well-written textbook to the medical profession.

NOTES ON BOOKS.

IN the fourth edition of *A Primer of Tropical Hygiene*,³ by Colonel R. J. BLACKHAM, is found in concise form information which, if put into practice, will reduce the sickness and mortality rate, not only among British residents, but among indigenous races. Great stress is laid on the importance of personal hygiene. Nearly every word in the book will also find an application to conditions found at home. The book is well written, and the whole subject of hygiene is dealt with in a brief, interesting, and instructive manner. Most would demur to the dogmatic

¹ *Psychological Medicine*. A Manual on Mental Diseases for Practitioners and Students. By Maurice Craig, M.D., F.R.C.P. Third edition. London: J. and A. Churchill. 1917. (Med. 8vo, pp. xii + 484; 27 plates. 15s. net.)

² *A Primer of Tropical Hygiene*. By Colonel R. J. Blackham, C.I.E., D.S.O. Fourth edition. Bombay: Claridge and Co. 1917. (Pp. 224, 1 rupee.)

¹ *Midwifery*. By Ten Teachers, under the direction of Comyns Berkeley, M.A., M.D., M.C., F.R.C.P. Edited by Comyns Berkeley, H. Russell Andrews, and J. S. Fairbairn. London: Edward Arnold. 1917. (Med. 8vo, pp. x + 736; 303 figures, 4 plates. 18s. net.)

statements that "pellagra is conveyed by midges," and that "acne is attributed to the action of the face mite." A few slips occur—for example, Pasteur Chamberlain is found twice on p. 82 where evidently Pasteur-Chamberland was intended, and on p. 167 carbonic acid is meant where carbonic acid appears in the text. The book will be found very useful to those attending lectures on tropical hygiene in connexion with the St. John Ambulance Association, under whose auspices it appears.

Professor COHEN's *Class Book of Organic Chemistry*⁴ is an admirable manual for first year medical students, who will find in it more than they require for examination purposes but not more than is good for them to know, and for senior science students in schools. Both the theoretical and the practical sides of organic chemistry are considered in it together. The general principles of the science are discussed first, then the paraffin compounds; lastly, the compounds of the aromatic series. Numerous tests for organic compounds are given, experiments and organic preparations are described, and questions dealing with the subject matter are set at the end of each chapter. The applications of organic chemistry to commerce are indicated, and the customary illustrations are given in the text. Describing illuminating oil, Professor Cohen gives a picture of a terra-cotta lamp from Lanuvium, a town in Latium that lies twenty miles from Rome, and looks across from the Alban hills to the Tyrrhene Sea. The book should be of great service to students of organic chemistry.

It has been said that the world in which we live is now governed by high explosives and low political intrigue. Those who wish to know about the latter need do no more than study the columns devoted to foreign news in the paper day by day. Those who want to learn much that is interesting about high explosives cannot do better than read Mr. MARSHALL'S *Short Account of Explosives*,⁵ a most opportune volume. Beginning with an account of black powder and similar mixtures, which have a vast field of service in industry, the book goes on to describe nitro-cellulose and nitro-glycerine, each the basis of a great series of high explosives. Two chapters are given to special military and commercial high explosives of all sorts. We are told that trinitrotoluene, also known as T.N.T. or trotyl in the British service, and elsewhere as tritolo, trinol, and trilit, was made in the laboratory in 1880, manufactured in 1891, and used for filling shells as long ago as 1902: an official account of the symptoms of poisoning by T.N.T. and the mixtures of it with ammonium nitrate, known by the names amatol and ammonal, will be found in the BRITISH MEDICAL JOURNAL of December 16th, 1916, on page 842. Other chapters deal with smokeless powders, fireworks, and the general properties of explosives, and a full account of the fuses and other means of detonating high explosives in both peace and war is added. Mr. Marshall writes clearly and has presented the lay public with a most interesting and intelligible account of the whole subject of explosives—as, indeed, was to be expected of the author of two massive volumes on the subject that have recently been published. His little book should have a wide popularity.

The thirty-seventh edition of Dr. H. W. GELL'S *Aid to the Injured and Sick*⁶ provides the lay public with a first-rate little manual of first aid. In its previous editions it has been before the world for thirty years. It is concisely and clearly written, and contains a very great deal of carefully chosen advice that should enable any one confronted with a medical or surgical emergency to carry on until the doctor comes.

The useful little book entitled, *Consumption: Treatment at Home and Rules for Living*, by Dr. H. WARREN CROWE, of Plymouth, has been adapted for use in India⁷ by Dr. C. A. SPRAWSON, of King George's Hospital, Lucknow. It contains a great deal of good advice, clearly and concisely put, mainly in the form of a set of rules to be followed by the consumptive at home.

⁴ *A Class Book of Organic Chemistry*. By J. B. Cohen, Ph.D., B.Sc., F.R.S. London: Macmillan and Co., Ltd. 1917. (Cr. 8vo, pp. 344; 62 figures. 4s. 6d.)

⁵ *A Short Account of Explosives*. By A. Marshall, A.C.G.I., F.I.C., F.C.S. London: J and A. Churchill. 1917. (4to, pp. viii + 96, with 29 illustrations. 5s. net.)

⁶ *Aid to the Injured and Sick*. By Henry Willingham Gell, M.A., M.B.Oxon., M.R.C.S. Thirty-ninth edition (revised). London: National Health Society. 1917. (Fcap. 8vo, pp. 40; 13 figures. 3d.)

⁷ *Consumption: Treatment at Home and Rules for Living*. By H. Warren Crowe, M.D.Oxon., and C. A. Sprawson, M.D., M.R.C.P. Lond. Adapted for India. Calcutta: Butterworth and Co. (India), Ltd. 1917. (Post 8vo, pp. ii + 41. 8 annas net.)

THE NEW VOLUNTARY FOOD RATIONS.

The following details of the new food rations, for the voluntary adoption of which the Food Controller strongly appeals, will be useful to medical men, who are likely to be consulted on the matter.

FOOD CONTROLLER'S NOTICE TO THE PUBLIC.

1. The position of the food supply is such that the utmost economy in the use of all kinds of food must be observed by all classes and by all persons.

2. In particular it is necessary that the strictest economy should be practised in the use of the staple foods: bread, flour, and other cereals; meat; butter, margarine, and lard; and sugar.

3. The weekly rations of these staple foods, which are stated in the following table for different classes of adults, according to their sex and occupation, should on no account be exceeded.

4. Children should receive their reasonable rations of these foods. Their individual needs differ so greatly that no definite ration is laid down for them.

Adult Rations per Head per Week.

Class.	Bread.	Other Cereals.	Meat.	Butter, Margarine, Lard, Oils, and Fats.	Sugar.
	lb. oz.	oz.	lb.	oz.	oz.
MEN.					
1. Men on very heavy industrial work, or on agricultural work	8 0				
2. Men on ordinary industrial or other manual work	7 0				
3. Men unoccupied or on sedentary work.	4 8	12	2	10	8
WOMEN.					
4. Women on heavy industrial work, or on agricultural work	5 0				
5. Women on ordinary industrial work or in domestic service	4 0				
6. Women unoccupied or on sedentary work	3 8				

The "bread" rations include all flour, whether used for bread or for cooking. Flour may be taken instead of bread at the rate of $\frac{1}{2}$ lb. of flour for every pound of bread.

The "other cereal" rations include oatmeal, rice, tapioca, sago, barley meal, corn-flour, maize meal, dried peas, beans and lentils, and all cereal products except bread and flour. The weight given is the weight of the dry article as bought. If the full bread ration is not used the amount saved can be taken in other cereals at the rate of $\frac{1}{2}$ lb. of cereals for every pound of bread saved.

The "meat" rations include the average amount of bone, which may be taken as one-quarter of the weight of the actual meat. Any parts of meat—such as rump steak, bacon, or suet—which are bought without bone must count for one-quarter more than their actual weight. On the other hand, any bone in excess of a quarter of the actual meat bought may be deducted. Poultry and rabbits may be counted at half their actual weight. The meat rations include suet.

Exchange of Bread and Meat.—Any person may take half a pound of meat over and above his meat ration in exchange for half a pound of bread to be deducted from his bread ration. Similarly, any person may take half a pound extra of bread in exchange for meat.

Milk and Cheese.—In addition to the economy necessary in regard to the foods mentioned above, it is essential that the consumption of milk and cheese shall be restricted as far as possible. These foods should be reserved for persons for whom they are indispensable.

Potatoes, Fresh Vegetables, and Fruit.—A more extensive use should be made of fresh vegetables and fruit, and, in particular, of potatoes, which are not rationed. This season's excellent potato crop supplies the means of observing the prescribed rations without privation, and it must not be wasted.

SOME CONSIDERATIONS ARISING OUT OF THE FOREGOING.

When compared with the scheme of voluntary rations issued early this year it will be seen that the main changes are that an attempt is made to adjust the amount of bread in relation to occupation and sex, that the amount of meat and sugar is reduced, and that "other cereals" and fats are rationed for the first time. Children are not rationed.

In order to arrive at an opinion on the nutritive value of the new rations the only means available is to estimate the calorie value, to compare it with estimates of the expenditure of energy for various classes of occupation and to note the amount to be made up from non-rationed foods.

While it is, for practical purposes, useless to carry the calculation to minute details in the following figures, it has for convenience been taken to the nearest whole number.

Taking first the rations which are not varied in accordance with occupation or sex we arrive at the following approximate results:

	Calories.
12 oz. "other cereals" a week = approximately	174 a day.
2 lb. meat " = "	297 "
10 oz. fats " = "	322 "
8 oz. sugar " = "	130 "
	923

Adding the variable ration we obtain the following results:

	Bread.	Total with other Rationed Foods.	To be made up from Non-rationed Foods.
MEN.	Weekly. Calories (daily).	Calories (daily).	Calories (daily).
1. Heavy work ...	8 lb. = 1,344	2,267	1,700
2. Ordinary industrial work	7 .. = 1,176	2,099	1,400
3. Sedentary work ...	4½ .. = 756	1,679	800
WOMEN.			
4. Heavy work ...	5 .. = 840	1,763	1,000
5. Ordinary industrial work or domestic service	4 .. = 672	1,595	800
6. Sedentary work ...	3½ .. = 588	1,511	500

In showing the amount of energy as expressed in calories required to make up the standard expenditure of energy beyond that supplied by rationed foods we have taken rates which may perhaps be considered pre-war—namely, for men in the three classes, 4,000, 3,500, and 2,500; and for women in the three classes, 2,800, 2,400, and 2,000. On this showing women come off better than men, but possibly the estimate of energy expended by women doing heavy industrial or agricultural work is a little too low.

The Food Controller makes a special appeal for more extensive use of fresh vegetables and fruit, and particularly of potatoes, of which the crop is excellent. It is, moreover, a perishable crop, and very liable to deterioration, even if carefully kept. On a rough estimate, allowing an average helping of potatoes at each of two meals in the day, and a fairly large quantity of vegetables and some fruit, 800 calories a day might be got from these sources. But this leaves a heavy deficit on men doing heavy or ordinary industrial work, and a deficit on women doing heavy work. The greater part might be made up without much difficulty from milk and cheese were it not that the Food Controller requires both to be restricted. Fish is not rationed, and an important addition can be made to diet at a cheap rate by using herrings, mackerel, and sprats. Two herrings, or three small herrings, will yield about 400 calories for 6d. or less. Salmon has about half the nutritive value of mutton, but so long as frozen Canadian salmon can be obtained at present prices, it is not an unduly expensive substitute for meat for persons in easy circumstances.

Perhaps a more useful way of looking at the matter is to take a family rather than an individual as the unit. Following what we understand to be the doctrine of Dr. Leonard Hill, we assume that a child over ten should be reckoned as requiring the same amount of food as a woman in domestic occupation. If we suppose a family of a father doing industrial work, his wife doing domestic work, and two children, we get a total energy expenditure of 9,500 calories and of receipts from bread and other rationed food 6,500, leaving 3,000 calories a day to be made up from non-rationed foods. Assuming that liberal use is made of potatoes, fresh vegetables and fruit, and fish, there should be no great difficulty in making up the 3,000 calories wanted, especially if the family purchases, say, 1 lb. of cheese a week and a pint of milk a day, for together they would yield about 600 calories a day.

BREAD RATIONS IN OTHER COUNTRIES.

It may be interesting to compare the figures for the amount of bread allowed in various belligerent and neutral

countries, published in a recent issue of the JOURNAL, with the new voluntary rations in this country. Reduced to grams the daily quantity of bread is in Great Britain, for men, 520, 455, and 292 in the three classes, and for women, 325, 260, and 228 in the three classes. In Germany the ration is between 260 and 280 a head a day; in Austria about the same; in Switzerland, Italy, and Holland, about 250; in Sweden about 260, and in Denmark about 215. No account is taken of the quality of the bread, and in Germany and Austria it is probably much inferior to the standard bread in this country. In France the allowance of bread is high; according to a recent statement by M. Gley at the Académie de Médecine it is 500 grams a day, but by supplementary allowances to which certain persons are entitled the total may be raised to as much as 900 grams a day; but even the lower amount is not always to be purchased. It is proposed now to reduce the allowance to 400 grams a head a day, without distinction of age or sex, with a supplementary allowance of 100 to 200 for persons engaged in laborious occupations. The French working classes are perhaps even more dependent on bread than British. M. Gley counsels them to make more use of potatoes cooked after the English manner, which is not commonly followed in France.

WORKERS' FOOD.

A new edition, revised with the assistance of Captain M. Greenwood, R.A.M.C., of Dr. Leonard Hill's report to the Health of Munition Workers Committee on workers' food, has been issued.¹ It was, unfortunately, prepared before the new rations were fixed, but it contains many useful suggestions. The only point to which we will at the moment refer is the insistence on the importance of establishing canteens at all munition works. It appears that a great deal remains to be done in this direction, for down to October, 1917, there were about 710 canteens in munition works employing about 920,000 people; this is only about 45 per cent. of all munition workers, so that there is no canteen provision for 55 per cent. Canteens, of course, do not cover the whole feeding of the workers, and where eight-hour shifts are worked the food taken elsewhere must form a large proportion of the total.

THE NOURISHING VALUE OF FOODS.

Professor W. H. Thompson, of Dublin, now scientific adviser to the Ministry of Food, has issued a second edition, revised and rearranged, of his pamphlet entitled *Foods and Their Relative Nourishing Value*.² It is a very practical handbook, opening with a section on the importance of the kitchen, in the course of which the author observes that cooking in town dwellings of the industrial classes is often extremely difficult owing to the absence of cooking arrangements and utensils. The composition and energy value of the more common foods are dealt with in a series of notes illustrated by diagrams, and there are excellent sections on the selection of foods, and on the need for making dishes attractive and the diet varied. In an appendix twenty-four recipes for using maize products in various ways are given.

THE COCAINE AND OPIUM REGULATIONS.

FROM time to time we have reproduced and explained in the JOURNAL and SUPPLEMENT various Orders in Council, issued under the Defence of the Realm Act, with regard to the sale of cocaine and opium. As it appears that misapprehensions still exist, it may be well to summarize once again the duties imposed on medical practitioners by these Orders.

The original Regulation relating to cocaine and opium was made under an Order in Council dated July 28th, 1916, and was numbered 40 B, by which number it is still known. Its text was published in the SUPPLEMENT of August 5th, 1916. The drastic restrictions upon the sale of cocaine were not extended to the prescribing and dispensing of opium in the form of ordinary medicinal preparations, opium being defined for the purpose of the Regulation as raw opium, or powdered, or granulated opium.³ Cocaine,

¹ Cd. 8798. Price 2d.

² Dublin: The University Press. Price 4d.; post free 4½d. This pamphlet is sold at the net cost of issue.

³ BRITISH MEDICAL JOURNAL, August 12th, 1916, p. 229.

on the other hand, was defined as including all preparations, salts, derivatives, or admixtures containing one part or more of cocaine in one thousand parts. The Regulations as to the distribution of cocaine make it an offence to be in possession of the drug, or to sell or to give it away, except under stated conditions. Thus cocaine may only be supplied either (a) to an authorized person, or (b) in accordance with the written prescription of a duly qualified medical practitioner.

Duly qualified medical practitioners are "authorized persons," and are, therefore, entitled to purchase and to be in possession of cocaine; but they may not prescribe or supply it to other persons except in accordance with the conditions laid down in the regulation. These conditions are as follows: A written prescription must be made out, which must be dated and signed with the prescriber's full name, qualifications, and address, and marked "Not to be repeated." The total amount of cocaine to be supplied on a prescription must be specified, but in the case of a proprietary medicine it is sufficient to state the amount of the medicine to be supplied. Cocaine must not be supplied more than once on the same prescription. The prescription must be retained on the premises where it is dispensed, and must be produced for inspection to any person authorized for the purpose by the Home Office. Chemists are forbidden to dispense cocaine on any prescription which is not in compliance with the requirements. It is understood that these requirements do not apply to cocaine *personally administered* by a medical practitioner; otherwise it will be noted that medical men who dispense their own medicines are bound by the same rules of procedure as the pharmacist. A prescription issued for National Health Insurance purposes on the form provided by the Insurance Committee need not be marked with the practitioner's address and qualifications, nor with the words "Not to be repeated."

Every person who has dealings in cocaine or opium is bound to keep records of his dealings in accordance with the provisions of the regulation. These have recently been amended, and are now as follows:

(a) He shall enter or cause to be entered in a book kept for the purpose such particulars with respect to all dealings in cocaine or opium effected by him as the Secretary of State may prescribe.

(b) He shall make the entry with respect to any transaction on the day on which the transaction is effected.

(c) Where he carries on business at more than one set of premises he shall keep a separate book in respect of every set of premises.

(d) He shall keep the book in some part of the premises to which it relates, so that it shall at all reasonable times be available for inspection by any person authorized in that behalf by the Secretary of State, and shall allow any person so authorized at all reasonable times to inspect it.

(e) He shall not cancel, obliterate, or alter any entry in the book, or make therein any entry which is untrue in any particular.

If any person fails to comply with any of the provisions aforesaid he shall be guilty of a summary offence against these regulations.

The precise form in which the record of dealings in cocaine and opium must be kept was reproduced in the SUPPLEMENT of August 12th, 1916. Medical practitioners dispensing their own drugs must keep a record in that form and in accordance with the above requirements whenever they dispense cocaine or preparations containing cocaine. As explained above, records of dealings in opium are not required except in the case of crude, powdered or granulated opium.

In the JOURNAL of December 9th, 1916, we published certain amendments to Regulation 40B. Under these a medical practitioner giving a prescription for the supply of cocaine otherwise than in accordance with the conditions laid down is made liable to a penalty, and a Secretary of State has power to direct that any medical practitioner convicted of any offence against the regulation shall cease to be an authorized person for the purposes of the regulation. It was also ruled that every article containing cocaine must be marked with the amount and percentage of cocaine contained in it. The latest amendments to Regulation 40B include stringent provisions for the prevention of opium smoking, but leave unaffected the sections dealing directly with the responsibilities of medical practitioners summarized above.

The report, published in the JOURNAL of November 3rd, 1917, of the prosecution of a firm of chemists for the

irregular sale of cocaine indicates that medical practitioners as well as chemists have not everywhere made themselves familiar with their duties under Regulation 40B. It is very important that they should do so. A print (October, 1917) of the Defence of the Realm Regulations which gives the revised terms of Regulation 40B can be obtained, price 6d., through any bookseller, or directly from H.M. Stationery Office, Imperial House, Kingsway, W.C.2.

THE PROBLEM OF THE SURGICAL TREATMENT OF DISABLED MEN.

A LECTURE on the problem of the disabled soldier and sailor in its surgical and industrial aspects was given at the Royal Institute of Public Health by Colonel Sir ROBERT JONES, C.B., Inspector of Military Orthopaedics, on November 14th, when King MANUEL was in the chair.

Sir ROBERT JONES said that wounded and disabled men formed a serious proportion of the population. They must be helped to remain an essential part of the economic man power of the nation—*independent producers and wage earners*, not helpless dependants. Fully 50 per cent. of the wounded in this war suffered from injuries which either were or might become physical disabilities; the proper treatment of these disabilities depended on the employment of methods commonly adopted by orthopaedic surgeons. In establishing Military Orthopaedic Centres the aim was to make the equipment of each complete. Each special department was directed by a specially trained surgeon, and these heads of departments were expected to hold consultations on doubtful cases; in this way each department learnt its own limitations and the strength of others. Orthopaedics in relation to military surgery should be defined as the treatment by operation, by manipulation, by reconstruction, and by re-education, of disabilities to arms and legs arising from injury or disease. Undoubtedly this was a wide definition, but it agreed with the circumstances. The orthopaedics of war might be divided into preventive and corrective. Speaking first of corrective orthopaedics, he said that owing to the fact that most gunshot wounds were already septic when they reached them, the energies of surgeons at the front had been taxed by the effort to save life, and it was inevitable that many cases reached England with various types of deformity and considerable shortening of the limb. The first duty of the orthopaedic surgeon was to consider how the limb—a fractured thigh, for instance—might be lengthened and lateral deflexion, which produced almost complete loss of function of the limb in walking, remedied. If, when the patient had been made to walk with an apparatus which prevented fresh shortening of the limb, he were then discharged, he would be improved but not cured; he was therefore retained in the orthopaedic centre until his joints became supple and his muscles were developed by intensive methods, including special forms of electric massage and exercises. Again, in the case of a stiff wrist or stiff elbow, with, perhaps, loss of part of one of the bones of the forearm, the surgeon first mobilized the joints, and then, if need be, grafted a piece of shin bone into the arm, the case being kept in hospital until the function of the arm was well on the way to restoration. In the same way, in cases of nerve injury it was necessary in the Orthopaedic Centre, first, to mobilize the joints and afterwards to operate by nerve suture or tendon transplantation. In the case of a man with a helpless flail hand certain muscles, which could be spared in the front of the forearm, were attached to paralysed tendons; in three months the patient might be able to raise his hand. How it was that muscles which had been engaged in flexing the wrist-joint should afterwards respond to a stimulus to extend the fingers was a curious psychological problem which remained for solution. Another problem with which the military orthopaedic surgeon had to deal was to decide if the elbow-joint, for instance, must be stiff, what was the best position in which to fix it. Usually a stiff elbow fixed at a suitable angle was better than a weak joint; but men engaged in certain trades would find a movable though weak elbow more useful than a stiff joint. All such factors must be considered when the choice of treatment was being made, and the patient must be consulted.

A great change in the *moral* of the men in orthopaedic centres had been brought about by the progress of military orthopaedics. At first they had grounds for fearing that if they accepted treatment designed for partial or complete restoration of function their pensions would be reduced. Now the mental attitude of the patient was altered by the fact that pensions were based on physical disability without reference to earning power, and that there were penalties in the form of reductions if treatment were refused. Men were now open to the persuasion of the hospital staff and of cured comrades; they derived direct benefit, mental and physical, from curative workshops. Such workshops had been in existence for many years at hospitals for cripples, but they were first established with purposeful intent as to special exercises in connexion with the Military Orthopaedic Hospital at Shepherd's Bush. The governing principle of curative work was that active movements—that is to say, voluntary movements—were of infinitely greater value than passive movements—those imposed from without. When the vast installations of Zander instruments and the way they were employed were considered, it was amazing that more tragedies did not take place. One gentle movement in every direction of a stiff elbow might overcome adhesions; to repeat the movements in a machine only endangered the tissues by direct irritation.

Exercises practised in curative workshops were of two kinds—direct and indirect. The ingenuity of the instructor was shown in devising direct curative work suitable to each case, but the indirect method was often the best; for example, when a man with a stiff ankle was set to plane or saw wood he unconsciously used the ankle as he became interested in the work his hands were doing. Again, if a man with stiff fingers who could not hold any tool was given something to do with the other hand, the crippled hand would come to the rescue in a difficulty and soon become useful.

There were now orthopaedic centres started, or on the point of starting, in London (Shepherd's Bush), Liverpool, Bristol, Cardiff, Leeds, Oxford, Newcastle, Birmingham, Reading, Netley, Edinburgh, Aberdeen, Glasgow, Dublin, and Belfast. Moreover, the various centres were being expanded. At Leeds, where six months ago there were 250 beds, there are now 1,800; in Liverpool, which started with 200, there are now 1,400. Owing to the control surgeons at the front had obtained over gas gangrene and sepsis the number of amputations was diminishing. Further expansion of orthopaedic centres had been authorized with the object of getting cases directly from the front in order that the occurrence of deformity might be anticipated and prevented. In this way the problems with which surgeons at these centres would have to deal would be simplified; a shortened limb could be lengthened without operation, a crooked limb moulded straight; patience and tenacity at this period would save the soldier a long period of suffering and enable him to be discharged to fight or work with the least possible delay.

If a man was discharged from the army to civil life he passed under the care of the Ministry of Pensions, which possessed great responsibilities and great powers for good. It could not compel a pensioner to undergo training, but it could bring pressure to bear upon him, for if treatment short of operation was refused, the pension was reduced, while bonuses were given to men who trained, and if they were married a separation allowance. Many pensioners would require treatment for two or more years, but it could be carried on while they worked or trained. This involved a scheme of great magnitude and administrative problems of great delicacy. The mentality of the wounded—war weary and sick of hospital life—must be understood, and the motto should be "from hospital life to industry." The kinds of industry which they could follow after the war should be explained to them, and they should be pulled back from the blind alleys of labour. The pensions machine must work sweetly and softly, lubricated by human kindness. There must be continuity of treatment from the moment a man left hospital until recovery was complete. Patients discharged from orthopaedic centres to civil life fell into two groups—Orthopaedic A, consisting of the partially disabled who required further treatment of an orthopaedic kind, and Orthopaedic B, who required a certain amount of treatment of a general kind. The Orthopaedic Centres

supplied to the first class a ticket giving a note of his condition, with suggestions to the pensions authorities as to the treatment he required. When accommodation was adequate the pensioner might attend the orthopaedic centre as an out-patient. In Newcastle permanent buildings grouped around the Victoria Infirmary were being established in the middle of the town; in other places, as in Liverpool, where the orthopaedic centre was five miles from the city, an annexe for out-patients was needed. An orthopaedic annexe, whether on the same site as the centre or on another, must supply an out-patient institute where massage and electricity could be provided, and a simple installation of hydrotherapy; it must also supply facilities for re-education and training; curative workshops would not be required, for pensioners would be sufficiently advanced to undergo educational training, which could often be given to them in the technical schools. The annexe should also be provided with hostels and billets where pensioners from a distance could stay for treatment or training, or both; there should also be an employment bureau. There would be a difficulty in remote places, which would have to be met by local authorities combining to establish hostels around which could be grouped the means of treatment and training. Facilities would be afforded for practitioners in towns to take part in the work of the centres, and gain experience of the methods and results of treatment. The great bulk of the work, however, would fall on the country doctors, who were generally a very receptive body of men. They would be asked to undergo training in the centres, and would be helped by periodical visits of inspectors with special orthopaedic knowledge. Cases which had undergone nerve suture ought to return periodically to the Orthopaedic Centres for examination as to the rate of return of sensation and the progress of muscular recovery, which must be accurately recorded from time to time—highly specialized work. The Pensions Ministry should encourage and pay the expenses of the pensioner for these visits. Success could only be attained when suitable conditions were provided. The treatment must be skilled, it must be continuous, and it must be lengthy; there must be a long period of watchful care after the surgeon had taken the first step towards cure.

When new Government departments are created it is very necessary that their responsibilities should be clearly defined; they should at the earliest moment know their respective powers and their limitations. Any difficulties of a departmental kind which interfered with the smooth working of the machine should be adjusted. When the nation was expectant of difficulties of a financial or departmental kind must be swept away. The medical profession was ready and anxious to do its part in the solving of a problem in which the whole profession was concerned. Its members should be given responsibilities sufficient to enlist their best energies, but they should be enabled to feel that the scheme, the success of which must depend largely on their efforts, is well thought out to the final end.

SURGEON-CAPTAIN ROBERT ASHTON BOSTOCK, formerly regimental surgeon to the Scots Guards, who died on August 7th of illness contracted on active service, left £71,365.

MM. EDM. and ET. SERGEANT described to a recent meeting of the Académie des Sciences in Paris a method of freeing an area from mosquitoes which takes advantage of the fact that the interval from the laying of the egg to the appearance of a perfect insect is, in Europe, three or four weeks. The actual duration depends a great deal upon the temperature, and in a tropical climate may be as short as seven or ten days, but for the Mediterranean littoral they put it at three weeks. Where it is necessary to have a collection of water near the house, MM. Sergeant propose that two receptacles should be prepared and filled and emptied alternately at the interval of about a week. The larvae hatched from eggs laid in the water by the female mosquito will be killed off while the receptacle for the water is dry, and in this way none would ever be able to develop into the perfect insect. They consider that the method would be much less expensive than any other in use, and on this ground alone their suggestion seems worthy of note, as there may be a good many places in which it could be applied, at any rate on a small scale.

British Medical Journal.

SATURDAY, NOVEMBER 17TH, 1917.

THE NEW VOLUNTARY RATIONS.

THE difference between the new and the old ration regulations which has most struck the public is the attempt to grade the consumption of bread according to occupation and sex, but it is to be noticed that the amount of meat and sugar is reduced, and that for the first time the amounts of "other cereals" and of fats (butter, margarine, lard, and oils) are specified. The general effect of the new ration of bread is to increase the quantity allowed. The maximum was formerly 4 lb. all round; this amount is now allowed for women on ordinary industrial work or in domestic service. It rises to 5 lb. for women on agricultural or heavy industrial work, to 7 lb. for men on ordinary industrial or other manual work, and to 8 lb. for men on very heavy industrial work or on agricultural work. The allowance for persons leading sedentary lives is for men $4\frac{1}{2}$ lb., for women $3\frac{1}{2}$ lb. For "other cereals," and for meat, fats, and sugar the allowance is not varied according to occupation or sex.

The additional allowance to men and women in heavy manual work is undoubtedly right; the only question is whether it is sufficient. It will certainly have to be supplemented by other foods rich in carbohydrates, but for this purpose dependence may for the present chiefly be placed on potatoes, although "other cereals" will help. Under the head of other cereals are classed for convenience not only oatmeal, barley meal, rice, tapioca, and maize products, but also dried pulses (peas, beans, and lentils). It is regrettable that the position with regard to cheese has altered, and that the Food Controller finds it necessary to ask that its use shall be restricted, for it is not only a popular but a useful and valuable article of diet, which, had it been plentiful, would have gone some way to make up for the reduction in the amount of meat and fats.

The Food Controller and his scientific advisers have acted wisely in making it plain that children are not to be rationed. In the first place, it would have been very difficult to do so without making the instructions far too complicated to be easily understood; and, in the second place, if anybody is to go short, it should not be the children. School children and young adults need a generous diet, for healthy growth is impossible if food is insufficient. The case is quite other with middle-aged and elderly persons; even when the manner of life is fairly active, the approach of age, which slows all the processes of the body, should be understood to call for a reduction of the amount of food habitually consumed. So also with younger persons leading sedentary lives who had for the most part got into the way, before the war, of eating too much, especially too much meat. Both classes will be all the better and more vigorous, physically and mentally, for a reduction of the amount of the foods now rationed that they have been in the habit of taking. Both classes also will do well to make vegetables and fruit a larger part of their diet.

The aspect of the new allowances for adults which will interest the medical profession most is whether,

with the limited rations of staple articles of food now proposed, the diet will be sufficient for persons who are doing hard work. The answer must be that it will probably fall below pre-war standards, but not very much below, when the constitution of the population as to occupation, sex, and age is taken into account. It must be remembered that fish, potatoes, vegetables, and fruit are not rationed.

A difficulty from which no scheme of food control can escape is that the rations prescribed or suggested must vary owing to fluctuations in the amount of various staple articles of diet in the country or in sight. The events of the last few months have illustrated this, for whereas there has been a failure of the cereal harvest in certain countries in Europe, there has been, in this country in particular, a copious potato harvest, due partly to the favourable season and partly to the success of the efforts to bring a larger area under cultivation. In France the average yield of the wheat harvest for the ten years before the war was 88 million quintals (tons) and the country imported 10 million in addition; last year the yield was only 40 million tons. Britain, France, and Italy must be considered as a unit for the purpose of buying grain, and these countries have in fact appointed a Wheat Executive, which, it would appear, acts in the main through a Wheat Commission sitting daily in London. The Wheat Commission buys in Australia, Canada, America, India, and Argentina. But it cannot always get delivery of what it buys, for the difficulty of transport is great, owing to the lack of shipping, due in some part to submarine sinkings, but largely to the diversion of so many ships to the transport of troops and for their supply in food and munitions. The Wheat Commission, for example, has paid for fourteen million quarters of wheat purchased from the Australian Government, but after the purchase was complete the shipping scarcity became acute and the great bulk of this wheat is still in Australia.

It must be understood that to prescribe maximum rations voluntarily or compulsorily is not the same thing as to undertake to supply the quantity permitted; the retail supply must depend largely on the actual stocks in the country, subject to such control as the Food Controller, with an eye to the future, can exercise. It is said, for instance, that flour for bread making is for the moment plentiful in this country, but it is estimated that before our next harvest several months' supplies must be brought from overseas. The rise in the price of wheat, due to shortage or threatened shortage of the stocks available for France, Italy, and the British Isles, may be partly controlled by such legislation as that which has come into force in the United States of America and in Canada, by which the price of wheat is fixed. Nevertheless, the decision of the Food Controller that wheat must be sold at a price allowing the public to purchase a 4 lb. loaf for 9d. will, it is estimated on the basis of consumption last month, cost the Wheat Commission £40,000,000 a year. The supplies of rice, sago, and tapioca have practically kept pace with the increased demands, while potatoes are at present abundant in this country, and the Food Controller feels justified in asking people to eat potatoes in place of bread. Sugar, on the other hand, has become scarcer, so that the available stocks are barely sufficient to supply the $\frac{1}{2}$ lb. a week a head now allowed. Fats, again, are still scarce; wholesale firms have little or no butter, and though the home manufacture of margarine is increasing, the supplies are not plentiful, and it has been necessary for the Controller to advance the price of lard. Bacon is scarce, so is cheese; eggs are

almost unprocurable, but this scarcity will be relieved when the hens begin to lay again freely after Christmas. The supplies of pulses, butter-beans and lentils, are limited. On the other hand, the home-grown crop of apples was sufficiently good to make it possible to meet all requirements for the moment, but the future is uncertain, since a supply for spring could only be procured by allowing imports to be resumed. Speaking generally, the fluctuations in the price of foods of all kinds have followed pretty closely the fluctuations in the world supply, and the international control now being exercised has checked profiteering, if it has not altogether put a stop to it.

The position of the country as to meat has not been clearly stated: apparently it has not been fully ascertained. The Food Controller has recently appointed live-stock commissioners in each of the food control areas of Great Britain. There are eleven such areas in England and two in Wales, while in Scotland there are six areas, each with a deputy commissioner, and one commissioner for the whole country. A census of live stock will be taken in each area to form the basis for determining the quota to be furnished. The commissioners will control farmers, auctioneers, and wholesale meat dealers with the object of ensuring that the call on the live stock of the country shall be evenly distributed. They will not be concerned with retail distribution, which will continue to be controlled, under the supervision of the Divisional Food Commissioners, by the Food Control Committees, which are responsible for the fixing of retail prices in accordance with the Food Controller's orders.

This country is going through a period of test and trial such as it has not known since the beginning of the nineteenth century. In some respects—in the toll of life—we are worse off than our ancestors, and the natural inclination is to ask to be given some definite job to help the country. Those who have not got such a job envy those who have, and will perhaps find but cold comfort in the statement of the Minister of National Service last Monday that economy and saving together constitute the first degree of national service, to work for the State the second degree. Economy in consumption, careful buying with an eye to the price of foods and relative nutritive value of each, and the saving of waste in the kitchen and at the table have become national duties in the first degree. The response of the housekeepers of the country to the first appeal voluntarily to ration their households was on the whole very creditable. But efforts have relaxed, especially since the price of bread was reduced—a measure which not unnaturally gave the impression, the wish being father to the thought, that the talk about shortage of wheat had been exaggerated. We know that it was not, and that the position is serious. We may hope that voluntary effort will be sufficient to enable us to win through. If not, compulsory rationing will have to be instituted, at great cost to the country and great inconvenience to the housekeeper.

THE PREVENTION OF BERIBERI AND SCURVY IN WAR.

IN an experimental research into the distribution in foodstuffs, especially of those suitable for rationing armies, of the substances necessary to prevent beriberi and scurvy, Miss H. Chick and Miss M. Hume¹ have made some definite discoveries which have the obvious merit, not always attached to scientific

advances, that they can at once be applied to the prevention of disease. Those two deficiency diseases, due to a want of accessory food factors or vitamins, as Funk called them in 1912, have been the subject of more investigation than rickets, pellagra, and some less known diseases of cattle commonly placed in the same group. But in view of the outbreaks of beriberi and scurvy among the troops in Mesopotamia any further light on their successful prevention is most opportune, and no doubt after the war the problems of rickets already undertaken by the Medical Research Committee will receive full attention.

The anti-beriberi vitamine is shown to be very widespread in natural foodstuffs, but mainly in the seeds of plants, such as cereals and edible pulses, and in the eggs of animals, where it provides for the well-being of the offspring during its early life. As a diet of decorticated or polished rice causes beriberi, and as the addition of the rice polishings and their extracts prevents or cures the disease, it has generally been held that the anti-beriberi vitamine is situated in the cuticle of the husked grain, in the layer of cells (aleurone layer) immediately under the pericarp. The authors establish the important point that the largest amount of the vitamine is deposited in the germ or embryo, which is also removed in the process of milling, and show that it is extremely resistant to drying; it can withstand exposure to a temperature of 100° C. for two hours, but is destroyed by a temperature of 120° C. under pressure. White wheat bread is deficient in the vitamine, and if used as the exclusive food will cause beriberi. Yeast is rich in the vitamine, but milk, cheese, and potatoes are poor; meat and other vegetables are moderately endowed in this respect, though they compare badly with eggs and the seeds of plants. The embryo and the bran of wheat should therefore, as in whole-meal bread and standard flour, be given to troops on active service, especially when the rations are mainly tinned, as these are devoid of vitamins on account of previous sterilization at high temperatures. Ordinary yeast is very disagreeable, but a palatable preparation has been provided in the form of soup cubes, and considerable quantities have recently been sent out to Mesopotamia. Though expensive, eggs, fresh or dried, should, at any rate, be given to hospital patients, who are otherwise often on a diet poor in the vitamine. Here it may be pointed out that, under the clinical label of beriberi, cases of acute polyneuritis, due to infection or toxæmia of undetermined or doubtful origin, may sometimes be included, and that all cases described as beriberi are not necessarily due to deficiency of the vitamine. This is rather a difficult question, and further investigation of the apparent exceptions to the view that beriberi is a deficiency disease is needed. For example, in the Gallipoli campaign a disease resembling beriberi was thought to be due, as Hamilton Wright previously suggested, to a specific duodenitis which provided the toxins responsible for the polyneuritis, but Wilcox and others upheld the vitamine hypothesis by pointing out that patients with intestinal disorders are often fed on tinned milk and other invalid articles of diet which are practically devoid of vitamins.

Turning now to the anti-scurvy vitamine, it is much restricted in its distribution as compared with that of the anti-beriberi vitamine, and is not collected into concentrated deposits. Present in all living tissues of plants and to a much less degree of animals, it is absent from dried vegetables and seeds, the vitamine being extremely susceptible to drying and comparatively easily destroyed by heat. Fresh fruit juices, cabbage, and onions, are specially rich in the anti-

¹ H. Chick and M. Hume, *Trans. Soc. Trop. Med. and Hyg.*, London, 1917, x. pp. 141-178.

ascorbic vitamin, potatoes and fresh meat are of less value, and milk is very poor in this respect. It appears that preserved lime-juice which was formerly so successful is now very feeble in preventing or curing scurvy; this failure, presumably due to some modern change in the method of preservation, is being investigated by the authors. Although dried seeds do not contain any vitamin, this accessory food factor is created afresh when they are moistened and as a result germinate. It therefore follows that in the absence of fresh fruit and vegetables, germinated pulses should be added to the diet after suitable preparation, the manner of which is described in an appendix to the paper. The dried seeds, which must be whole, should be soaked in water for twelve to twenty-four hours according to the temperature (90° to 50° F.), and after the water is poured away the seeds are allowed to germinate for twelve to forty-eight hours according to the temperature (80° to 50° F.). The germinated pulses should then be cooked and eaten as soon as possible after germination as it is important that they should not become dry.

A diet deficient in both these vitamins may naturally cause both beriberi and scurvy; but scurvy takes longer than beriberi to appear and, according to Hehr, does not develop under four months. The various degrees in which the two diseases may blend was shown in the "Rand scurvy" seen some few years ago.

PRINCIPLES OF ORTHOPAEDIC TREATMENT.

In his lectures at the Royal College of Surgeons of England during the present winter session Professor A. Keith will deal with anatomical and physiological principles underlying the treatment of injuries to muscles, joints, and bones. The after-treatment of injured soldiers has compelled a review of the principles on which the practice of orthopaedic surgeons is founded. The principles must be based on a knowledge of the behaviour of muscles under normal and abnormal conditions. Professor Keith will review the principles and practice of John Hunter on November 23rd, of John Hilton on November 26th, of Hugh Owen Thomas on November 28th, and of Stromeyer, Adams, Wolff, and others on November 30th. The researches of modern neurologists will receive full attention in the lectures to be given in the following week. The first, on December 3rd, will deal with the application of discoveries made by Marshall Hall, C. E. Beever, and Duchenne, while in those on December 5th and 7th the bearing of the discoveries of British neurologists on orthopaedic practice will be discussed and explained. The lecture on December 10th will be devoted to the principles underlying the practice of modern British orthopaedic surgeons, that on December 12th to the American school of orthopaedic surgeons, and the last lecture, on December 14th, to orthopaedic practice in France and Italy. The lectures, which will be illustrated by specimens from the army medical collection now on exhibition in the museum, will be given on each day at 5 p.m., and are open to all medical men. The second series of the course will be given in January.

THE PHYSIOLOGY OF FLYING.

The great expansion of the air services during the war has led to an accumulation of knowledge by medical men engaged in looking after aerodromes and in the examination of candidates for aviation. In this country a few articles on the subject have recently appeared, such as those by Staff Surgeon H. V. Wells,¹ who employed the term "aerosthenia" to describe nervous symptoms arising usually in pupils unsuited for flying, and by Temporary

Surgeon H. G. Anderson,² and no doubt others are in preparation. In France, the birthplace of modern aviation, much has been done both before and since August, 1914, and a useful summary of this has recently been given by Binet,³ who has been investigating the psychomotor and emotional reactions in flying men by means of an instrument designed by Langlois. The pulse rate quickens during the ascent and slows during the descent, but is quicker after landing than it was before the start. There is considerable difference of opinion as to the behaviour of the arterial blood pressure; some state that it is raised, others that it falls, and according to Gemelli, an Italian observer, the systolic pressure falls and the diastolic rises. The respirations become more rapid and shallow during the ascent, slow down during the descent, and after landing are more frequent than before the flight. Vision becomes more acute, whereas hearing is impaired, and headache and noises in the ears occur. The auditory disturbances can usually be relieved by swallowing. Sleepiness, which may persist after landing, is not uncommon; tremor due to fatigue and delay in the psychomotor reactions may be noted. These symptoms vary in degree in different persons, and this variable coefficient has been called by Bonnier the "manostatic capacity," which depends on centres in the lower part of the medulla concerned with the maintenance of equilibrium between the pressures inside and outside the body. When exaggerated, these disorders constitute airman's asthenia, and include extreme fatigue, giddiness, headache, tremor, loss of confidence, low blood pressure, unstable pulse, and delay in the psychomotor reactions. Such individuals are ineligible for aviation. Among the causes of these symptoms attention is naturally directed to changes in the atmospheric pressure, excessive exposure to wind and cold, mental strain, and physical fatigue. Much discussion has taken place as to the mode of action of diminished atmospheric pressure, and it may be pointed out that Mosso attributed mountain sickness to a diminution of the amount of CO_2 in the blood or acapnia, a condition which Yandell Henderson considers to be responsible for surgical shock. Luciani vigorously opposes Mosso's view. The influence of a deficiency of oxygen still remains as a problem requiring further elucidation. The necessary qualifications of an aviator are normal acuity of vision and colour vision, normal binocular field of vision; normal hearing, healthy middle and internal ears, and especially perfect power of balance; healthy respiratory and cardio-vascular systems; and a calm mental state without any exaggeration of the reflexes, but with the power of rapid and accurate response as tested by examination of the psychomotor reactions. The normal visual ($\frac{1}{15}$ second), auditory ($\frac{1}{10}$), and tactile ($\frac{1}{15}$) reactions are delayed in alcoholics, morphinomaniacs, convalescents from infective diseases, shock, head injuries, fatigue, and mental distraction.

A CHEMICAL TEST FOR THE EARLY DIAGNOSIS OF ENTERIC FEVER.

DR. E. DE SILVESTRI of Turin has recently published⁴ an account of a simple test for typhoid and the paratyphoid fevers that should prove of great service if—and there is, alas! always an if about these simple diagnostic tests—it turns out to be as effective in other hands as it is in those of its discoverer. It is a urinary test, a colour reaction, and is applied by carefully floating 3 c.cm. of the filtered suspected urine on to 2 c.cm. of iron perchloride solution acidified by the addition of four or five drops of the purest sulphuric acid in a test tube. If a chestnut-coloured or yellow-brown ring forms at the level of contact between the urine and the acidified iron perchloride, the result is said to be positive and the case one of the enteric group of

¹H. V. Wells, *Journ. Roy. Nav. Med. Serv.*, London, 1915, i, 55-60; 1916, ii, 65-71.

²H. G. Anderson, *ibid.*, 1917, iii, 328-331, and *BRITISH MEDICAL JOURNAL*, 1917, ii, p. 124.

³L. Binet, *Rev. gén. des sciences*, Paris, 1917, xxviii, 540-515.

⁴*Medicina Nuova*, Biella, 1917, N. 27 and 28.

fevers. The coloration spreads rapidly up into the supernatant urine; it is not discharged by heat or by shaking. If albumin is present, it should be got rid of before the test is applied. The strength of the perchloride solution employed is not stated; Dr. de Silvestri describes it as the "official solution of perchloride of iron," and this is probably the strong solution of the Italian pharmacopoeia, containing 10 per cent. of iron or 29 per cent. of ferric chloride. The strength of the solution of pure sulphuric acid used is not specified. A positive reaction is obtained almost regularly after the first few days of an attack of typhoid or paratyphoid fever, and generally disappears in the third week, returning again if a relapse occurs. A positive reaction is also seen after antityphoid inoculation, but for how long is not stated. Sometimes, too, a positive reaction is seen in febrile tuberculosis, influenza, rheumatic fever, and other diseases characterized by high temperatures. In these instances, however, the reaction is negative at the outset of the disease, only becoming positive when the fever is fully developed; so that a positive reaction is still of value for the early diagnosis of fevers of the enteric group, with the qualification that it must not be employed if phenolic drugs (such as salicylic acid or its derivatives) have been exhibited. Dr. de Silvestri has found a positive reaction in 95 per cent. of some 200 cases of typhoid and paratyphoid fever in which he has applied his test. It will be interesting to see if other observers obtain equally satisfactory results with this simple method of diagnosis.

CHINA MEDICAL BOARD.

FROM time to time we have noted the praiseworthy efforts made by the Rockefeller Foundation for the promotion of scientific medicine in China. In 1914 a commission left the United States for China, and upon its return made a detailed report to the Foundation, with the result that before that year was out the China Medical Board was created. The aim of the board is to promote the gradual and orderly development of a comprehensive and efficient system of medicine in China. The report of its first year's work was published early in 1916; the second report records co-operation with the several missionary societies in strengthening their medical schools and hospitals by means of grants in aid. The main work of the board, however, has been, and is, the founding of two medical schools—one at Peking, the other at Shanghai—of the same type as the better medical schools of the United States and of Europe. It appears that the reorganization of the Peking Union Medical College has already been undertaken, upon a plan agreeable to the trustees and to the Chinese Government. In accordance with the recommendation of the Commission the English language has been determined upon as the medium of instruction, and the Chinese language will not be required of all members of the faculty. Dr. Franklin C. McLean, from the Rockefeller Institute Hospital, is the first professor of medicine and physician-in-chief. Owing to the fact that students in preparatory schools and colleges in China do not at present receive sufficient instruction in science to enable them to undertake the work of a high grade medical school, the board has had to decide whether to aid a number of colleges to strengthen their scientific departments, or to create a school of its own. The latter policy was favoured as a temporary arrangement, and the immediate intention is to appoint a pre-medical school at Peking. It is hoped, however, that the colleges of North China will be able in a few years to advance their courses in science sufficiently to prepare students for the medical school. In April, 1916, the China Medical Board proposed the establishment of a medical school at Shanghai; this was approved by the Rockefeller Foundation, and sufficient funds were set apart to provide the plant and maintain the school. In addition to giving direct aid to missionary hospitals the board hopes that when its two medical

schools are well established it may be possible for missionary doctors to be released for periodical post-graduate courses therein. This policy should prove of great benefit to medical missionaries and their patients. The total amount appropriated to mission hospitals for expenditure during the year 1916 was more than 158,500 dollars, including handsome sums contributed to the Union Hospital at Nanking for buildings, equipment, and general expenses. Post-graduate scholarships and fellowships have also been granted to medical missionaries and to Chinese doctors, nurses, and pharmacists.

RADIUM IN CANCER.

A REPORT has been issued by the Cancer Committee of Harvard University¹ giving the results of the use of about 235 milligrams of radium in the treatment of 642 cases of cancer and allied conditions at the Collis P. Huntington Memorial Hospital from September, 1913, to January, 1916. The conclusion of the authors of the report, Drs. W. Duane and R. Greenough, is that in many cases of advanced, inoperable, and recurrent cancer radium therapy may do good in relieving pain, diminishing discharge, checking hæmorrhage, lessening the size or even causing total disappearance of the growth, and improving the general condition. The beneficial effect on the patient's mind must also be taken into account. In a very small number of advanced cases the improvement was such as to warrant a radical operation. In about 35 per cent. of superficial types of cancer without metastasis, and in a much smaller number of metastatic cancers, radium is capable of doing away with the clinical manifestations of the disease. In a limited number of cases recurrence took place even after apparent destruction of the lesion. In keratosis, papilloma, and other affections of the skin regarded as pre-cancerous, radium was effective in abolishing the clinical manifestations in from 48 to 60 per cent. It proved of special value in recurrent and inoperable carcinoma of the cervix or body of the uterus, inoperable squamous carcinoma of the tongue, jaw, and buccal mucous membrane, and in non-metastatic epidermoid cancers. On the other hand, radium was of little benefit in recurrent or inoperable carcinoma of the breast, stomach, intestine, glands of the neck, cancer of the tongue, mouth, and lips, and in deep-seated metastatic extension of cancer from any region. Its use as a preventive of recurrence after operation is not recommended. Where the affected area is superficial and accessible radium may be used with benefit, but not after operation for breast cancer. The combination of radium treatment and operation gave satisfactory results in several cases, and is adapted to the more advanced cases of rodent ulcer.

THE CLIMATE OF BAGDAD.

SURGEON-GENERAL ENATT, in his essay on the medico-military topography of the Persian Gulf and Valley of the Euphrates and Tigris, founded on a journey made in 1873 and published in the Army Medical Department Report of 1874, said that the weather of Bagdad from November to March was pleasant though cold. Rain, he said, fell in January and February to the amount of 25 in. in twenty-nine rainy days. In April the weather began to get very warm, and in May a fierce heat reigned; a hot wind blowing over the heated and unwatered desert burnt up everything. Residents who could afford the luxury built up screens of camel thorn, a prickly succulent plant: these screens being well watered, the heated wind blowing through them became a cool breeze. In June, also, the weather was very hot, and, with a southerly wind, enervating, for, as it was loaded with moisture from the Persian Gulf, there was no evaporation from the skin. In July and August, both very hot months, the nights were cool, and as there was no dew every one slept on the flat housetops. The thermometer, he stated, rose highest

¹ Boston Med. and Surg. Journal, September 13th, 1917.

in August—107° F.—and was lowest in January, when it fell to 45° F. We learn from *Nature* that Professor Filippo Eredia has recently published a memoir on the climate of Bagdad in the *Bollettino* of the Royal Italian Biographical Society. It was founded on a mission dispatched under Dr. A. Lanzani in 1908. According to the observations of this mission it appears that the mean annual temperature is 73° F., ranging from 94.5° in July and August to 48.9° in January. The mean of the daily maxima is 86°, the mean monthly values ranging from 109.9° in August to 59.5° in January. The mean of the night minima is 60.1°, highest in July, 79.5°, and lowest in January, 38.1°. The highest temperature recorded was 122°, and frost is not uncommon from November to February. The mean daily range of temperature varies from 33° in August and September to 20° in December. The relative humidity is 58, rising to 80 per cent. of saturation in December and January, and falling to 38 per cent. in June. The mean cloud amount (overcast sky = 100) is only 16, the extremes being 29 in March and 1 in July. Various authorities place the annual rainfall between 6.94 in. and 9.04 in., practically all of which falls between November and April. June, July, and September are rainless, but slight showers have fallen in May, August, and October.

GERMAN SOCIETIES AND BRITISH MEN OF SCIENCE.

It appears that certain Fellows of the Royal Society view with displeasure the practice of some of their colleagues of appending to their names in the year book of the society and in various directories the fact of their membership of German academies and scientific societies as an honour which they value. It is suggested that it would be more consistent with the actual state of affairs were such mention omitted. It is pointed out that the declaration of war by Germany was received with enthusiasm by practically every section of the German nation, and that the professors who formed the backbone of the German scientific academies and societies were prominent as a whole in arousing this enthusiasm. It was largely due to them, it is added, that a belief was created in German minds that Germany was superior to other nations and that in consequence it was only right that German power over other nations should be extended. No German scientific academy or society has, so far as is known, made any protest against the many infringements of humanity and of international law which have been characteristic of the German conduct of the war. As the Fellows of the Royal Society may be assumed to reprobate the German Government in bringing on the war and its methods of conducting it as much as any other section of British folk, their colleagues who have taken the lead in this matter invite them to drop the mention of membership of German scientific societies or academies, with a view to bringing home to German scientific men that learning and research cannot be divorced from public conduct. Among those who have signed a circular letter intimating their intention to take this course are Sir David Ferrier, Sir James Dewar, Sir W. H. Perkin (Oxford), Sir Ronald Ross, Professor J. N. Langley, Professor C. S. Sherrington, Professor E. H. Starling, and Dr. W. M. Bayliss.

NIGHT BLINDNESS.

THE late Mr. Nettleship gave a great deal of time to the study of night blindness, and obtained a number of interesting pedigrees. He was able to induce two cases, which figured in these pedigrees as being of the congenital type, to submit themselves to spectroscopic examination by Sir William Abney and Professor Watson. The results of the examination have recently been communicated to the Royal Society. The interesting fact appeared that in the extinction of the different rays of the spectrum all light disappeared throughout the spectrum at the same moment

that the colour vanished, and that the colour vanished to the normal eye at the same point that it did to the colour-blind. This pointed to the fact that the colourless part of the rays had failed to give any sensation of light. As normal eyes see in a faint light with these colourless rays, it is to be presumed that the night-blind owe their blindness in faint lights to the absence of certain retinal processes which the normal eyes possess.

EARLY SYMPTOMS OF TETANUS

THE importance of recognizing the onset of tetanus at the earliest possible moment is generally recognized, but the diagnosis is sometimes delayed because the true meaning of the earliest symptoms is not understood. The initial symptom may be pain in the back with no assignable cause, but in men who have been wounded any anomalous symptom should be suspected as a hint that tetanus may be about to develop. As an instance, the case of a man with a gunshot wound of the buttock may be mentioned; the foreign body was removed, but six weeks later he complained of urgency of micturition, with difficulty and finally inability to pass urine. Catheterization revealed great spasm of the sphincter and the force of the bladder's contraction almost expelled the catheter; he was little relieved by drawing off the urine, and during the later stages had almost continuous spasm of the bladder. The ordinary symptoms of tetanus developed four days after the difficulty in micturition began, and he died.

A MINISTRY OF HEALTH.

ON November 13th representatives of the Ministry of Health Committee, which has been appointed by the Council, held a conference at the offices of the Association with representatives of the Joint Committee of Approved Societies, in order to discuss the scheme for a Ministry of Health which the latter has prepared and embodied in a bill.¹ Both parties to the conference were agreed as to the need for a Ministry of Health, and there was complete agreement on the principle that the central organization must not be a department of a Department of State, but a Ministry created for the sole purpose of dealing with matters concerned with the health of the community. Opinion was divided as to the expediency of insisting that reorganization of local health administration should take place simultaneously with central reorganization. After an interesting debate on the general aspects of the matter, it was decided that a further conference should be held between three or four representatives from each side, with the object of examining in more detail the various proposals that have been made, and of ascertaining the precise points upon which there is agreement or disagreement. It is hoped that this will clear the ground for future consideration, and indicate how far, if at all, joint action is possible between the insurance organizations and the British Medical Association.

A MUNITION WORKS SURGERY.

IN the current issue of the *Dilution of Labour Bulletin* appears an abstract of a paper by Dr. Mark R. Taylor on the working of a surgery at a munition factory where some 2,500 men and women are employed in the making of shells. The organization for the treatment of accidents at this works has been in existence for eighteen months. The staff consists of a part-time medical officer, assisted by nurses, two of whom are always on duty. The medical officer attends daily at the surgery to see cases which have been held over for his inspection or are in need of re-dressing, and examines new workers for physical defects before engagement. He also treats at his own house patients sent to him by the nurses on duty. Every accident, however trivial, is reported at once and the worker sent to the surgery. Thus every wound is dressed within

¹ BRITISH MEDICAL JOURNAL, October 27th, 1917, p. 559.

a few minutes of its occurrence, and is cured for until healed. The results of the treatment of accidents have been classified into three periods of six months each. They show that the percentage of workers losing time on account of injuries became less when the system was fully established. Analysis of the results points very strongly to the value of close medical supervision in munition works and of the immediate treatment of injuries no matter how slight. In the same factory an outbreak of dermatitis was investigated by Dr. Taylor and Mr. L. H. Debenham, B.Sc., and was traced to the use of lubricating oil containing micro-organisms similar to those cultivated from sores on the workers' hands. The most effective means of preventing this condition was found to be the installation and regular use of efficient washing accommodation. Dr. Taylor's paper is of special interest at the present time when all munition works are required to possess ambulance facilities under competent supervision. In the memorandum on sickness and injury issued last year by the Health of Munition Workers Committee, attention was drawn to the urgent need of improvement in the provision made for treating accidents in munition factories, simple first aid organization being required rather than elaborate provision for the treatment of minor injuries.

Medical Notes in Parliament.

The Representation of London University.—It is an evidence at once of the tact and parliamentary strength of Sir Philip Magnus that he was able last week to secure the separate representation of London University under the new Reform Bill. The Government proposal, adopted from the Commissioners' report, was to group the University of London for parliamentary representation with the Universities of Durham, Manchester, Liverpool, Leeds, Sheffield, Birmingham, Bristol, and Wales as a joint constituency returning three members. Sir Philip Magnus pleaded that London University should be allowed to keep its identity, and Sir George Cave ultimately made the concession—the only amendment to the redistribution scheme which was accepted. The total number of university representatives remains the same, inasmuch as the group formed by the remaining universities will in future have two members. The numerous medical graduates of the university will have the greater pleasure in noticing the personal achievement of Sir Philip Magnus, seeing that he has so often undertaken to present the views of the medical profession in regard to various matters before the House of Commons.

Proposed Air Force Medical Service.—In moving the second reading of the Air Force Bill, which proposes to unify existing air services under one Ministry, Major Baird said that one of the most important needs was for a specialized medical service. Research into the methods of prevention and cure of the disabilities to which flying men were subject had advanced very rapidly; but so long as the flying services remained appendages of the army and navy it was difficult to provide for the study of these medical matters and for the special treatment of the patient. Knowledge on the subject was limited almost entirely to those few medical officers and civil practitioners who had had considerable numbers of flying men continuously under their care, and it was necessary at once to take special measures to provide separate accommodation for the cases and separate staffs to concentrate on the problems which had arisen. The mere selection of candidates for the flying services had become a highly specialized business, and the standard of fitness required for flying was diverging from the standard required for the ordinary naval and military services. There were many minor physical imperfections which rendered a man unfit for flying, but which if taken in time might be removed or cured. Still more important, many precautions had to be taken to enable pilots who had obtained their certificates to maintain their fitness under the severe conditions of modern air warfare. These were only examples of the

necessity for securing a body of men whose sole business should be to concentrate on that particular branch of medical science which was necessary for the welfare and well-being of our flying men.

Powers of Local Authorities as to Child Mortality.—In answer to Mr. Anderson, Mr. Hayes Fisher said that in 1916 the number of deaths of children under five years of age registered in England and Wales was 109,966. It was not possible to state exactly how many of these were due to preventable causes, but he was satisfied that if the local authorities in England and Wales were given the same powers as local authorities in Scotland and Ireland, and if they used them as there was reason to believe they would, a great reduction in the number of deaths, not only of infants, but of mothers, would be effected. The Local Government Board had for some time been anxious to secure for local authorities the extension of powers, and local authorities had pressed for it, but, owing to opposition from insurance organizations, the legislation had been delayed.

Amending Insurance Bill.—The present intention is that the second reading of the amending Insurance Bill, the scope of which is described in the SUPPLEMENT, shall be taken in the House of Commons early next week. There has been some lobby talk of opposition by approved societies on account of the proposals for varying the allocation of contributions and other financial changes proposed. But it is understood that Sir Edwin Cornwall and the Insurance Commissioners were in consultation with representatives of approved societies when preparing the measure, and the hope of the Government is that it may be carried through Parliament more or less as an agreed measure, any discussions on possible amendments to be conducted in a conciliatory spirit. If there be serious opposition to the bill there is little chance of its passage this session.

The Army Medical Service in France.—Major David Davies asked whether the Director-General of Army Medical Services had entire control over the Royal Army Medical Corps attached to the British Expeditionary Force in France. Mr. Macpherson: No; the Commander-in-Chief in each theatre of war exercises entire control over all troops under his command.

Hospital Stoppages of Army Pay.—General Croft asked Mr. Macpherson whether the announcement some weeks ago that hospital stoppages were to be discontinued applied to officers. Mr. Forster replied that the announcement made dealt only with the pay of men. The question of officers would not be overlooked.

Shell Shock and Neurasthenia.—Colonel Clive asked a question as to shell shock patients at the 4th London General Hospital at Denmark Hill and other similar cases at Golders Green, suggesting that their condition was aggravated by air raids, and that they should be removed to a quieter area. Mr. Macpherson replied that it might be possible to discontinue the neurological centre in London as a treatment centre in connection with changes now being made. The inquiry as to Golders Green should be addressed to the Minister for Pensions. In reply to another question, Mr. Macpherson said that neurasthenic cases varied much in degree, and it had not been thought necessary to impose by regulation any period which should elapse before a neurasthenic returned to duty. The matter was, however, now being reconsidered in the light of the experience gained regarding these cases.

The Renewal of Artificial Limbs.—In reply to Major Chapple, Sir Arthur Griffith-Boscawen said it was recognized that a large proportion of the men who were fitted with artificial limbs had to return for the limb to be refitted within six months or a year, but it was not possible from available statistics to state the exact proportion. The refitting was necessitated by shrinking of the stump, but this shrinking would not take place simply as the result of the passage of time, but also as the result of the pressure of the socket of an artificial limb. There was no evidence that the limbs were being fitted prematurely. The policy of supplying a provisional limb of a simple type before the fitting of the permanent limb was one on which surgical opinion was divided. It had been adopted in some cases, and its wider adoption was under consideration.

Provision for Disabled Nurses.—In reply to Major Chapple, Sir A. Griffith-Boscawen said that he had seen in the newspapers the appeal for subscriptions to provide endowment for the College of Nursing and a benevolent fund for individual nurses themselves. The provision made by the State for nurses disabled through war service was set out in the warrant of last August. This provision was on a far more liberal scale than any previously given, and he did not doubt that the organizers of the fund would take account of the assistance provided in deciding how their fund should be applied.

THE WAR.

THE WORK OF THE ARMY MEDICAL SERVICE IN THE RECENT FLANDERS ACTIONS.

SPECIAL ORDER BY GENERAL GOUGH.

A SPECIAL ORDER was issued under date October 30th by direction of General Sir H. de la P. Gough, praising the manner in which the work on the Passchendaele-Ypres front has been carried on in the army under his command. The Order runs as follows:

"The Army Commander desires me to express his appreciation of the excellent work which has been, and is still being, done by the Medical Services in connexion with the active operations on this front. He considers that the manner in which this work has been performed reflects the greatest credit on all concerned.

"The evacuation of sick and wounded from the front to the Casualty Clearing Stations has been most carefully organized and successfully carried out, while the professional skill and attention displayed at the Casualty Clearing Stations, together with increased comfort provided for the patients, has led to highly satisfactory results being obtained."

These high terms of commendation will not be a surprise to our readers, who will remember that earlier in the year an equally high compliment was paid to the medical services by General Plumer, soon after the conclusion of the Messines offensive.

It is clear, therefore, that the medical service working under Sir Arthur Sloggett, the Director-General of Medical Services in France, is fully maintaining the reputation for high efficiency that it has won, and that the opinion to this effect entertained by the general public at home has the authoritative confirmation of the combatant branches of the British Expeditionary Force. Nothing does more to sustain the moral of men engaged in heavy fighting than the knowledge that if they happen to "stop something," their injuries will receive skilled and careful medical attention forthwith. Sir Arthur Sloggett's chief lieutenants in the armies engaged in recent operations are Surgeon-General Robert Porter, C.B., and Surgeon-General Bruce Skinner, C.M.G.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Wounded.

Surgeon J. J. Keatley, R.N.
Surgeon W. P. Starforth, R.N.

ARMY.

Killed in Action.

CAPTAIN K. A. MACCUSH, C.A.M.C.

Captain K. A. MacCush, Canadian Army Medical Corps, was reported as wounded in the casualty list published on November 7th, and in that of the following day as having died of his wounds.

Died of Wounds.

CAPTAIN W. G. MCCONNELL, R.A.M.C.

Captain William Gardiner McConnell, R.A.M.C., died of wounds on October 13th, aged 26 years. He was the second son of the late Mr. John McConnell, Brookeboro', co. Fermanagh, and of Mrs. McConnell, Toronto, Canada. He was educated at the Royal School, Cavan, and at the Royal College of Surgeons, Dublin, taking the diplomas L.R.C.P.I. and L.R.C.S.I. in March, 1915. He took a temporary commission as lieutenant in the R.A.M.C. on October 1st, 1915, and was promoted captain in August, 1917. He was married whilst on leave from France, only a month before his death.

Died on Service.

CAPTAIN H. L. HESLOP, R.A.M.C.(T.F.).

Captain Harold Linton Heslop, R.A.M.C.(T.F.), died on October 30th of acute gastritis at a casualty clearing station, aged 36 years. He was educated at Durham University, where he graduated B.S. in 1903, and M.D. in 1906. After acting as house-surgeon of the Tynemouth

Jubilee Infirmary, he went into practice in Sunderland, where he was honorary assistant surgeon to the Children's Hospital. He joined the 7th (Territorial) Battalion of the Durham Light Infantry, as lieutenant and medical officer, on January 11th, 1910, was promoted to captain on January 11th, 1913, and went to the front with his battalion early in April, 1915. He leaves a widow and one child.

Wounded.

Lieut.-Colonel H. Fulton, R.A.M.C.
Major N. E. Kirkwood, M.C., Australian A.M.C.
Major J. Muirhead, Australian A.M.C.
Captain W. R. Addis, R.A.M.C. (temporary).
Captain J. Gapp, R.A.M.C. (temporary).
Captain A. E. Huxtable, R.A.M.C.(T.F.).
Captain W. P. Jepson, R.A.M.C.(S.R.).
Captain T. J. Kelly, R.A.M.C. (temporary).
Captain D. Macnair, R.A.M.C.(T.F.).
Captain H. S. Moore, R.A.M.C. (temporary).
*Captain J. Morris, M.C., R.A.M.C.(T.F.).
Captain M. A. Power, R.A.M.C. (temporary).
Captain J. F. M. Sloan, M.C., R.A.M.C. (temporary).
Captain K. H. Stokes, R.A.M.C. (temporary).
Captain C. Wynne, R.A.M.C. (temporary).
Lieutenant D. W. Anderson, R.A.M.C. (temporary).
Lieutenant A. P. Draper, R.A.M.C. (temporary).
Lieutenant J. A. C. George, M.C., R.A.M.C. (temporary).
Lieutenant E. H. Good, R.A.M.C. (temporary).
Lieutenant W. H. Orton, R.A.M.C. (temporary).
Sister E. I. Devenish-Meares, Q.A.I.M.N.S.R.

DEATHS AMONG SONS OF MEDICAL MEN.

Butler, Edward Lawrence, Cadet, elder son of Major A. Butler, R.A.M.C.(T.F.), of Port Glasgow, killed October 21st, aged 20.

Douglas, Ian Victor, M.C., Second Lieutenant Royal Garrison Artillery, youngest son of Dr. Thomas Douglas of Sapperton, formerly of Cape Town, killed October 25th, aged 20.

Turrell, H. G., Second Lieutenant Oxford and Bucks Light Infantry, only son of Dr. Turrell of Oxford, died at St. Thomas's Hospital on November 3rd of wounds received on August 23rd, aged 19.

Williams, O. S. G., Lieutenant Royal Engineers, youngest son of the late Dr. Morgan Williams of Cardiff, killed October 23th. He had twice been wounded, and returned to the front for the sixth time in September.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

INTERALLIED SURGICAL CONFERENCE.

A SURGICAL conference attended by representatives of the military medical services of the allied powers was opened at the French Army Medical School, Val-de-Grâce, Paris, on November 5th by M. Justin Godart, Under Secretary of State for the French military medical service. This conference, the third of its kind, was the first attended by American surgeons in addition to those of Great Britain, France, Belgium, Italy, Portugal, Serbia, and Japan. The conference sat for several days and discussed a number of important subjects, including the treatment of injuries of the joints, the late results of fractures of the femur, late secondary results of brain wounds, and the functional results of operations on the peripheral nerves.

GARDEN CITIES FOR THE DISABLED.

A scheme for the establishment of village settlements in which the restorative treatment of officers and men disabled in the war may be combined with industrial and social reconstruction has been made public by a provisional committee, of which Dr. R. Fortescue Fox is chairman; the other medical members are Sir Robert Armstrong-Jones, Dr. Egbert Morland, Sir George Savage, and Mr. Wilfred Trotter. The main objects of the scheme are: (1) To restore discharged disabled soldiers and sailors to health of mind and body; (2) to train them for settlement in villages and on the land; (3) to encourage the founding of small self-supplying village communities where local industries and handicrafts may be pursued on sound lines. An essential feature of the scheme is the encouragement of home life, self-government, and self-development. While the main purpose will be to heal and train as many men as

possible and pass them on to begin life elsewhere; a certain number of selected men will have opportunities to settle with their families and form the basis of a permanent village settlement. The committee wish to begin with a site of one square mile as a centre for a thousand disabled men at a time; of these the majority would be trained in agriculture and kindred subjects, the rest would be taught handicrafts and business pursuits. The period of treatment and training would vary according to circumstances, but three months will be the minimum. Medical considerations will determine the hours of work, and of curative treatment. The following types of case are considered most likely to benefit by such a scheme; (1) Cases of shell-shock, neurasthenia, and depression; (2) men crippled by wounds or by stiff joints or wasted muscles; (3) amputation cases; (4) certain cases recovering from fevers, and delicate men for whom a country life is prescribed. Incurables will not be received, nor those still requiring surgical aid or hospital treatment. The patients will not be segregated according to kinds of disability, but will live, work, and be treated in common, in order to avoid the intensive effects of grouping together numbers of men suffering from a particular form of abnormality. In selecting a trade or course of training each case will be considered upon its merits, with special regard to medical needs, natural tastes and abilities, and the prospects of financial success. The aim of the workshops will be to reproduce the best features of the old craft guilds, as opposed to the modern factory system. It is hoped that the presence of their wives and children will induce the men to settle down happily to prolonged periods of training; this, with the substitution of self-government for military discipline should prove one of the most attractive features of the scheme. Much will depend upon the personal qualities of the staff, and on the care with which the men are selected. The committee recognize that the cost of the scheme will be heavy, but they hope to convince the Government, as well as public and private benefactors, that the results will more than repay the relatively heavy expense. From the foregoing outline it will be seen that the idea, although ambitious, has strong claims for sympathetic consideration. The honorary secretary is Miss Hilda A. Fox, 36, Devonshire Place, W.1.

SHELLING OF HOSPITALS.

According to a statement issued by the Rumanian Embassy the town of Galatz was bombarded by the enemy on October 11th and 12th. Altogether 170 shells and bombs fell on the town. The principal hospital, in which there were 650 wounded and nurses, was hit by thirty-two shells. Several patients and nurses were dangerously wounded, the chapel was destroyed, and the hospital had to be evacuated. The Rumanian Government raises the strongest protest against this bombardment of a hospital, and, in accordance with Article 3 of the Hague Convention of October 18th, 1907, will hold the enemy responsible for all the damage done.

Scotland.

The Hawick Town Council has arranged to establish a maternity and child welfare centre with office and consulting rooms. A health visitor will be appointed and will reside at the centre. Bailie Wilson has given £500 towards starting a child welfare centre and the gift of a house for a day nursery is expected.

MANUAL CURATIVE WORKSHOPS.

The manual curative workshops erected as an annexe of the orthopaedic department of the Scottish National Red Cross General Hospital, Bellahouston, Glasgow, from funds contributed by the workers of Messrs. Weir's Holm Foundry, Cathcart, was opened by Lady Weir on November 5th. The sum of £8,000, out of the £14,000 collected since September, 1914, has been allocated for the purpose. The gift was accepted on behalf of the Scottish Branch of the Red Cross Society by Sir George T. Beaton, K.C.B., who has written a pamphlet on the purpose and equipment of curative workshops. Those at Bellahouston include shops for carpenters and joiners, leather workers, tailors, and boot repairers. There is also a smithy in which metal splints can be made and a room for moulding and fitting. It is hoped also to establish a small printing press and a painter's shop. These shops are not designed to give men permanent occupation, but

mainly with the object of hastening recovery, though at the same time the aptitude of men for any special trade will be discovered.

AFTER-CARE COLONY FOR TUBERCULOUS SOLDIERS.

At a meeting of the Joint Institutional Committee of the Scottish Red Cross and the Ministry of Pensions in Edinburgh, on November 10th, under the presidency of Sir A. Griffith-Boscawen, Parliamentary Secretary to the Ministry of Pensions, a discussion took place on the subject of tuberculosis. It was stated that the Minister of Pensions had come to the conclusion that the present system of treatment in a sanatorium for a limited period was insufficient, and that he proposed as an experiment to institute a more prolonged course of treatment combined with industrial training in an after-care colony. Sir R. W. Philip, who attended, gave particulars of the colony at Polton, administered by the Edinburgh Corporation, and explained his views as to its possible use for soldiers and its extension. The matter was referred to a committee.

REPORT OF THE ROYAL COMMISSION ON HOUSING.

We mentioned recently that the Royal Commission on housing in Scotland, appointed five years ago, had presented its report, and quoted the Commissioners' summary of the nature and magnitude of the evils to be remedied. The report is very voluminous, containing 460 pages, 110 being occupied by the minority report. Neither report is particularly well put together; in neither are the recommendations collected and arranged so as to show the interdependence of the various sets of recommendations scattered through the report; neither report is provided with an index. It is not easy, therefore, to give an abstract, and any voluntary organization which undertook to do this, and to prepare an index, would render a real service, for the facts and discussions contained in the two reports are undoubtedly of importance, not only to Scotland, but as a contribution to the housing question generally. The percentage of one roomed houses in Scotland is very high. In 1911 it was for the whole of Scotland 12.8; in Edinburgh it was 9.5; in Glasgow (the extended city) it was 20.1. The percentage of two-roomed houses in Scotland is 40.0; in Edinburgh, 31.4; and in Glasgow, 46.3. The figures with regard to overcrowding are also very unsatisfactory. In Scotland in 1911 the percentage of the total population living more than two in a room was 45.1; more than three in a room, 21.9; and more than four in a room, 8.6. In Edinburgh the percentages were 32.6, 12.7, 4.1 respectively. In Glasgow 13.8 per cent. of the population live in one room; 48.4 per cent. in two rooms, and 21.1 per cent. in three rooms.

The majority report contains an instructive story of the history of housing legislation; it dates back to 1855, when the Dwelling Houses (Scotland) Act was passed. The failure of this and subsequent Acts both in Scotland and England led to the appointment of a Royal Commission in 1884, which, though it mainly investigated conditions in England, put on record evidence sufficient to show that the housing conditions in Scotland at that time were very bad. Better things were hoped from the Housing of the Working Classes Act, 1890, which repealed all the previous Acts, and gave full powers for providing healthy dwellings. Then followed the Public Health Act for Scotland in 1897, and the application of the Housing Amendment Acts to Scotland in 1899, and the passage of the Housing and Town Planning Act in the same year. Yet the Commissioners say that the housing conditions of Scotland at the beginning of the twentieth century were "little if any better than they were fifty years before; in some ways they were worse. In many areas they were worse, because of the inevitable overcrowding resulting from the influx of rural dwellers in the towns, the result of the industrial revolution which had been going on for fifty years, and because the building of healthy houses had not kept pace with the increase in the population. Private enterprise had, prior to the war, almost completely ceased to provide working-class houses."

The Commissioners discuss at great length the reason why this had happened, and agree that the main reason, shortly, is that even before the war the cost of building three-roomed houses with sanitary and domestic conveniences was so large that the rent the possible inhabitants could pay was not economic. The architectural inspector

of the Local Government Board put the cost before the war at £225 in and around the industrial areas, and £275 north and south of those areas. It is estimated that the cost under war conditions would be £450 at least, and the Commissioners think it unsafe to assume that on an average during the next fourteen years such houses could be built for less than £350 each. They estimate (1) that 121,430 additional houses are required to get rid of the overcrowding due to more than three persons in a room, and to take the place of houses requiring instant demolition; and (2) that, in addition, 114,560 houses are required to take the place of 50 per cent. of the one-room houses, and 15 per cent. of the two-roomed houses. On the basis of £350 a house, these 235,990 houses would cost £82,596,500. They then calculate that at least one-third of the cost will be uneconomic and must be contributed by the State in some form or other. The higher rate of interest now commanded by money influences the finance of any scheme to a very serious degree.

The majority propose that the expenditure of this eighty-two millions odd should be spread over fourteen years; this would mean an expenditure of about six millions a year, of which the State subsidy would supply two millions. They advise that the State grant should be funded and the difference between the house rentals and the total outgoings made up to the local authorities each year; at the end of seven years the State should make a valuation of the houses erected during that period and wipe off the whole loss by paying the difference between the cost of the houses and the ascertained value. The majority, while holding that for a period of years after the war it will be impossible to build such houses at a cost which would yield a commercial return, admit that such a state of matters may not always prevail; the minority agree that there must be an element of subvention in housing finance after the war until the rate of interest and building cost return to more normal levels. But they hold that a fixed proportionate grant is not necessary in all districts, and desire to give more encouragement to building societies and owner occupiers. Further, they express the view, with which many, including not a few employers, will agree, that employers have a responsibility, of which they cannot wisely be relieved, for the housing of their workers. The arguments are strong for the "tied" house in agricultural districts, that is to say, a farmer should be able to make sure that the cottages attached to the farm are used by men working on the farm. The majority are strongly opposed to subsidizing private enterprise, but the minority, being anxious to encourage building societies and the owner occupier, consider that private enterprise ought to be encouraged, and believe that about a quarter of the total capital expenditure might thus be obtained.

Ireland.

QUEEN'S UNIVERSITY, Belfast, has accepted the offer of Mr. J. H. Stirling of Belfast of a gift of war stock to found a silver medal in the department of pathology, in honour of Colonel J. G. Adami, F.R.S., Professor of Pathology in McGill University, Montreal. The medal will be awarded annually and will be known as the Adami medal.

In the paragraph on the treatment of venereal disease in Ireland, which appeared in this column last week, it was stated that the Local Government Board for Ireland would repay 25 per cent. of the approved expenditure incurred under the regulations by sanitary authorities. The figure should have been 75 per cent.

The resignation of Captain William Ormsby, R.A.M.C., formerly medical officer for the Ballyleague Dispensary District of the Roscommon Union, has been accepted. Captain Ormsby has been on active service since war broke out, and at the first battle of Ypres was so severely wounded that amputation of the leg was considered necessary. He is still in France.

ULSTER MEDICAL SOCIETY.

The opening meeting of this society was held in the Medical Institute, Belfast, on November 8th. The outgoing President, Mr. Robert Campbell, F.R.C.S., occupied

the chair, and introduced his successor, Dr. William D. Donnan of Holywood, who gave an opening address, in the course of which he mentioned the advances in medical science brought about by the war, and gave some personal recollections of his student days, and the advances in surgery during the last twenty-one years. The second half of the paper was devoted to the relations of chemical and chemico-physical science with medicine. The living cell was an essential chemical machine, and one by one its products, which were formerly supposed to be purely "vital," had been produced synthetically in the laboratory. Enzymes, toxins, and the potentialities of colloidal matter were discussed.

Sir John Byers, in an amusing and telling speech, proposed a vote of thanks to Dr. Donnan for his address, and to Mr. Campbell for his labours during the past year; this was seconded by Dr. McKisack, and acknowledged.

Professor Lindsay, vice-chairman of the Ulster Branch of the National Council for Combating Venereal Diseases, made a short statement on the present position in regard to the prevention and treatment of these diseases. Sir John Byers asked whether the Local Government Board and the Public Health Committee were to be allowed to put forward a scheme without consultation with the profession; such consultation was ordered in the papers of the Boards in England and Scotland; he proposed a resolution asking the Boards that the profession should be consulted; this was seconded by Mr. R. Campbell, and after a number of members had joined in the discussion, was passed unanimously.

England and Wales.

INSANE AND MENTAL DEFICIENTS IN 1916.

PART I of the Report of the Board of Control for the year 1916 has recently appeared in modest pamphlet form of 73 pages, in lieu of the voluminous Blue Book of pre-war days. It again records a diminution in the number of notified insane, the number under care in England and Wales being 134,029 on January 1st, 1917, as compared with 140,466 on January 1st, 1915. The statistics show a falling off of 3,159 during the year 1916; if the average annual increase noted during the ten years previous to 1915 had been maintained, the number estimated for January 1st, 1917, would have been 144,968, nearly 10,000 in excess of the actual number recorded. The relative sex percentages under care in 1916 were: males 45.7, females 54.3, against 46.2 and 53.8 respectively in 1914. The fact that on January 1st, 1917, there were nearly 2,000 mental and nervous cases under observation in military hospitals, of whom a certain number will probably eventually be certified as insane, would appear partly to account for the disparity in the two sexes. The diminution was mainly amongst rate-aided cases (the so-called pauper class), the private patients under care on January 1st, 1917, being 9,876 (males 3,765, females, 6,111), a decrease of 25 on the figures of the previous year; the criminal patients numbered 1,028. The total admissions during 1916 were 20,701 (472 less than in 1915); those discharged recovered 6,839, and "relieved" or not recovered 2,962; and the deaths were 13,608, or 219 in excess of those in 1915.

Information is given as to the number of male attendants who had joined the colours up to the end of 1916. The total number of male attendants on lunatic patients in institutions (not including staff otherwise employed) was at the commencement of the war 6,496, of whom 5,289 were of military age; of these 2,681 had joined before the operation of the Military Service Acts, 1916, when the Board recommended 922 for permanent and 601 for temporary exemption, but of the latter all but 27 had been called up by January 1st, 1917. Thus it would seem that more than 50 per cent. of the original number of asylum attendants have been serving in the army, and this percentage would be considerably larger if the reservists mobilized at the outbreak of war were included.

The total expenditure in connexion with county and borough asylums for maintenance and structural expenses in 1916 was £3,575,451, and the average weekly cost of maintenance 11s. 7d. per patient. The number of suicides reported was exceptionally low—only 4 within asylum

precincts, though 18 deaths had resulted from self-inflicted injuries, in 9 cases committed previous to admission, in 4 during absence on trial, and in 1 after escape. Cases of dysentery and diarrhoea showed an increase in six of the larger asylums and a decrease in five; open-air treatment had been tried with beneficial results; 648 deaths from these causes were recorded.

As the result of war conditions local authorities have done comparatively little to meet the obligations imposed on them by the Mental Deficiency Act, 1913. So far 6,836 cases (3,093 males and 3,743 females) have been brought under the supervision of the Board of Control, either in certified institutions or houses, approved homes under guardianship, or notified. Eight new institutions were certified during 1916, bringing up the total of certified institutions to forty-four, in addition to which some thirty institutions had been approved under Section 37; and there were nine certified houses and 21 approved homes in operation at the end of 1916.

Canada.

THE CANADIAN ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

At the seventeenth annual convention of the Canadian Association for the Prevention of Tuberculosis at Ottawa on September 26th last, under the presidency of the Hon. J. W. Daniel, M.D., of St. John, New Brunswick, the Secretary (Dr. George D. Porter), in submitting a report, said that the general interest in tuberculosis and its prevention had been deepened by the war; the present situation in France had been an object lesson to the world on the importance of preventive measures. In Canada there were 1,194 tuberculous soldiers under treatment at an average cost of about 1,300 dollars a year for each patient. Of these, about 35 per cent. had never been overseas. In addition, there were hundreds of Canadian soldiers undergoing treatment for tuberculosis in England. During the past year the association had been greatly assisted in its educational campaign by the Government, which had granted an allowance to cover the cost of all literature distributed, and also franking privileges. In 1914 the sanatorium accommodation in Canada was about two thousand beds; since the war began this accommodation had been greatly increased by the Military Hospitals Commission. Sanatoriums already in existence had been enlarged and many of them were now devoted exclusively to military patients. The Government had accepted responsibility for the tuberculous soldier, and it was to be hoped that it would now recognize its responsibility to the civilian patient and lend its aid to the antituberculosis movement, which up to the present time had been entirely voluntary. The Secretary closed his report with an acknowledgement of the indebtedness of the association to the Imperial Order of Daughters of the Empire and the Victorian Order of Nurses, who had lent continuously both co-operation and support. Several papers dealing with the military aspects of tuberculosis were read.

In a paper on tuberculo-is and maternity Dr. D. A. Stewart of the Ninette Sanatorium, Winnipeg, said that in Canada each year no fewer than 2,400 tuberculous mothers gave birth to children, and in the province of Ontario 700 of the 63,000 children born in a year were the offspring of tuberculous mothers.

The presidential address was delivered in the evening by the Hon. J. W. Daniel, M.D., who gave a brief review of the work already accomplished by the association; he reminded his hearers that in the province of Ontario the death-rate from tuberculosis had been reduced from 149 to 91 per 100,000. The public address was given by Dr. W. A. Evans, of Chicago, the President of the United States Public Health Association. Dr. J. A. MacLado, of Ottawa, was elected President for the year 1917-18.

Resolutions were passed in favour of the establishment of tuberculosis clinics in all cities, the extension of the anti-tuberculosis movement to the training and for the protection of the youth of the country, the examination of recruits by chest specialists, and the pasteurization of all milk and cream used in the manufacture of butter. The question of a Federal Bureau of Public Health was again

brought up, and it was resolved to urge upon the Government the necessity for establishing such a department.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.

The sixth annual congress of the Canadian Public Health Association took place at Ottawa on September 27th and 28th, the two days following the meeting of the Association for the Prevention of Tuberculosis. Dr. J. D. Pagé, Chief Immigration Office at Quebec, was in the chair. Among the various subjects discussed, that of national health insurance was of particular interest in that it was the first time the question had been considered at length at a medical meeting in Canada. Dr. Charles J. Hastings, of Toronto, advocated a system on the lines of the Insurance Act now in force in Great Britain. The question is one that is attracting a good deal of attention just now in Canada; it is probable that some such measure will be passed in the near future, and in his annual address the President of the Canadian Medical Association, Dr. A. D. Blackader of Montreal pointed out to members of the profession the advisability of giving careful consideration to this question.

A discussion took place on the prevention of venereal disease, during which Captain Gordon Bates, C.A.M.C., of Toronto, spoke of the alarming prevalence of the disease; he urged that the facts should be laid frankly before the public, and that the time had come when more efficient measures should be adopted to prevent the spread of the disease among the civilian population; in the army periodical inspection and quarantine had been adopted. A campaign had recently been inaugurated in the province of Ontario to prevent the spread of the disease and to educate the public, and two deputations, consisting of members of the profession, the chief of police, and city aldermen, recently waited on the Ontario Government with the request that venereal disease be classed and treated as a contagious disease.

Dr. Pagé, the president, took as the theme of his address immigration problems in Canada. The methods of inspection employed by the Canadian Government, he said, were far behind those in use in the United States, where the steamship companies are held responsible for the class of immigrants brought to the country. A number of other papers dealing with various aspects of public health work were read. Dr. W. H. Hattie of Halifax, Nova Scotia, was elected president of the association for the ensuing twelve months.

Correspondence.

THE BRITISH MEDICAL ASSOCIATION AND ORGANIZATION OF THE PROFESSION.

SIR,—There are now several "unions" and "associations" purporting to organize the profession, apparently all started upon the supposition that the British Medical Association is unfitted to do the work. By "British Medical Association," as far as I can see, they mean "the officials," whom they consider liable for all mistakes, shortcomings, and even the "cumbersome constitution." Herein lies the fallacy and the root evil causing subdivision.

The British Medical Association is of the profession, for the profession, and by the profession, who can make of it what they please; the only conditions being that they find out what they want, and work unitedly to attain their object, going on the committees or putting men on who can express their desires, following the work that is being done, and assisting by writing to those committees their (constructive) ideas if unable to do more active work.

General practitioners years ago altered the constitution to please themselves, made the British Medical Association democratic, and yet time after time since the Insurance Act have members rendered the work of a whole year useless through neglecting to advise, help, or criticize until the final stage, that is, the Annual Representative Meeting, when they have vetoed or "returned for further consideration" plans which, had they taken the trouble to understand them, could have been used in a slightly altered condition forthwith.

New bodies are, in my opinion, redundant and destructive to unity of the profession, and to belong to two or

three is waste of money; let all such bodies present constructive policies to the British Medical Association, and the need for their separate existence will cease, when all joining the one Association the profession would become the strongest "union" known to the United Kingdom, trade unions not excepted.

The one weakness which appeared to me in 1912 to exist, and for which I pointed out a remedy by circular letter to all Local Medical Committees early in 1913, is that there is not sufficient opportunity for personal verbal presentation and discussion of important matters (as opposed to lengthy printed reports). I was co-opted on the State Sickness Insurance Committee then considering organization. I proposed all areas to be arranged into twelve groups for the whole United Kingdom, each group to have a whole-time paid medical secretary (or agent), who should interview small parties of practitioners, ascertaining their views, presenting them properly to the British Medical Association, where they would be collated and discussed; and, afterwards, should arrange small informal meetings at doctors' houses, where the results could be laid before them whereby data for a well-considered, universally acceptable policy could be collected.

Such was embodied in one section of the "Special Fund" sent to Divisions several times and thrown out by the Annual Representative Meeting, though I admit it was somewhat swamped by such items as life and sickness insurance, etc., not acceptable to me. Had these been eliminated by the Annual Representative Meeting the organization part could have been worked at about 10s. a head to the profession.

Is it not yet possible for the Panel and Local Medical Committees to group themselves in some such way and see that these twelve men shall next year be elected on the Insurance Acts Committee? These men would get into touch with those not members of the British Medical Association, who, finding valuable work done for them, would surely join, so rendering the smaller bodies unnecessary. Local Medical Committees are purposely included, as all branches of the profession, whether accepting work under it or not, will soon be affected by the Insurance Act, and the profession as a whole, sinking "panel" and "non-panel," should join for the good of the whole; at present there seems a danger of "panel" losing sight of this.

As it is, about 5 per cent. to 10 per cent. of men attend meetings, and but few of the remainder ever take the trouble to return even prepaid question forms. Consequently hardly anyone outside the Committees, Panel or British Medical Association, knows what is going on till it is finished and issued as regulations or policy, as may be, when there is a great hue and cry about being "let down" and "not consulted," whereas the man who wears the shoe must show where it pinches before it can be eased, so the practitioners should point out difficulties to the British Medical Association, not only to each other.—I am, etc.,

Ealing, W., Oct. 21st.

HARDING H. TOMKINS.

THE REMUNERATION OF RURAL PRACTITIONERS.

SIR,—As the value of money has so altered and all insured persons are earning increased wages, all insured persons can afford to contribute 6d. a week—possibly the employer should contribute an extra 1d. This would give the Government 10d. a head a week (most clubs pay out about 2s. a week in sickness for each 1d. contributed). The patients would then receive in sickness, men, 12s.; women, 10s.; the doctor, 10s. per member, without dispensing; and the chemist, 3s.—I am, etc.,

Andover, Nov. 11th.

J. BATTEN COMBE.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—The Rural giant has good naturedly been sleeping while his betters have been arranging his toil and its reward. Now he has begun to stir and mutter in his sleep. Perhaps he will soon sit upright and rub his eyes.

What have the Commissioners offered to Rural men in the way of mileage? They have actually said very little about the matter. What they seem virtually to say to us is this: "We expect you to make your way unaided

within a circle whose diameter shall not exceed six miles. If you are a pedestrian you may walk. If you prefer you may cycle. If you own a car you may use it, naturally at your own expense. You will incidentally (at least in the day time) enjoy the beauties of Nature both in summer and in winter, while the fresh air and exercise will prove beneficial to your personal health." But how long should a man be content with rubbing his eyes?—I am, etc.

October 23rd.

CALIBAN.

SIR,—I beg to protest against the flagrant misstatement in the latest memorandum of the Commissioners, which you publish on page 72 of SUPPLEMENT (October 20th).

Section 11. The difficulties are inherent in the particular system of remuneration which the profession in 1911-12 made a condition of acceptance of service under the Insurance Acts.

In the agreement signed January, 1913—Terms of service:

Section 8. The practitioner shall immediately after April 14th, 1913, furnish an account stating the number of insured persons on his list.

Each practitioner was definitely promised (December, 1912):

Section 22. If he has 1,000 insured persons on his list for the year he will receive at least £325. With 6d. for tuberculosis and 6d. for drugs it will be £375.

This was a plan so simple, honest, and straightforward as to be almost above criticism. The difficulties are inherent in the Commissioners' plan, which is so cumbersome and different as to be almost beneath criticism. Insured person days were never dreamt of in our diplomacy. In fact, for no list of 1,000 insured persons, however carefully kept, has there ever been paid the £375 promised. That insurance rate was agreed to for ordinary times in which the rate on the healthy lives paid for the attendance on the sick. Conscription, by taking the healthy and leaving all the sick, has deprived panel practitioners of about a million pounds a year for doing the same work. The Commissioners say (Section 17) the result is "obviously" an "over-payment" because thereby a greater number drop out of benefit during the first half of the year! They say, in consequence, many women become insured persons, women who paid us better as private patients for less sickness than war work causes. And they use conscription as an excuse for giving us discharged soldiers to doctor. To induce us to attend for nothing the disabled soldiers, on account of whom nothing is paid into the central pool (Section 18), they hide behind the unquoted statement of some unnamed actuary who certainly never said an unlimited class of permanent invalids was balanced by the odd days without benefit of a much smaller class. He would certainly tell the Commissioners that to pay only the average rate for the specially diseased and aged classes left by conscription is to under-pay insurance practitioners.

We know the rate for insurance is higher the shorter the period. To insure for one day the rate is much higher than for a year. We agreed to a yearly rate. (Quarterly in the second agreement.) But we are paid for insured person days and denied the higher rate involved.

That payment is postponed and we are deprived of the interest accrued. List inflation is deliberately rewarded so as to deprive us of payment for the unassigned class who have not chosen a doctor.

I remember that the Commissioners are paid to control the funds from which doctors are paid, and that they have, in fact, well earned their salaries by repeatedly altering their method of calculating, so that each time we doctors should get less, until their cumbersome administration costs more than the total funds which the panel doctors get all together.

Remember and demand the right of audit and straightforward settlement.—I am, etc.,

Croydon, Oct. 22nd.

T. ARCH. DICKES.

THE PROVISION OF MEDICAL TREATMENT FOR DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—Will you allow me to deal with this subject from the non-panel point of view, and thus, I hope, to relieve in some measure at least the minds of certain practitioners who seem to think their interests may be compromised by non-panel practitioners having the opportunity of sharing in the remuneration for attendance under the statutory

provisions now made? I appeal to the Association for active support in this matter.

The conditions asked for by non-panel practitioners, also unanimously supported at the annual meetings of the Edinburgh Branch and the Edinburgh and Leith Division of the British Medical Association, were:

1. That any provision made for medical attendance on discharged disabled soldiers and sailors ought to be outside the National Insurance Acts.
2. That this provision ought to be made under conditions which will allow of these persons being attended by any registered medical practitioner they may respectively choose.

No. 1 was lost by the terms of the National Insurance (Part 1 Amendment), Act, 1917. No. 2 is now lost through the regulations under the 1917 Act. Instead of letting it be open to these men to have their medical benefit from any registered medical practitioner they may choose they can only have it from such as are already on the panel, or, if not on the panel, as enter into an agreement "for the treatment of any invalided soldier who may apply to him for treatment upon the same terms and subject to the same conditions as are contained in the agreement for the time being in force between the Committee and practitioners on the panel," etc. (see National Insurance, Benefits of Invalided Seamen and Soldiers Regulations (Scotland) 1917, page 4, par. 9, and Memorandum 234/L.C. (Scotland), page 6, par. 29). The usual capitation method of payment is replaced by one of payment according to attendance, but this may only be temporary.

Those practitioners, therefore, who have felt bound to refrain from joining the panels, because they held the conditions of service to be derogatory to the profession and against the public interest, have the same objections to undertaking attendance on discharged disabled soldiers and sailors under the conditions now imposed. Many of those who will come within the scope of these provisions were previously attended as private patients, some by non-panel practitioners, others by insurance practitioners in their private capacity, and in either case would presumably have continued to be so attended after their discharge from service. We hold that these men who have suffered in the service of their country deserve better than to be told that the Government makes medical provision for them only under the conditions of the National Insurance Acts. Surely it would have been possible to have made the provisions more generous and acceptable all round.

The Council of the National Medical Union has unanimously passed, and the Medical Guild (Scotland), at its annual meeting, has unanimously endorsed, the following resolution:

That the National Medical Union advises its members and all other non-panel medical practitioners to refrain from attending discharged disabled soldiers and sailors under the "Special Arrangements" of the Insurance Commissioners, but encourages treatment in their private capacity.

The National Medical Union and the Medical Guild are not opposed to the principle of health insurance, but they are opposed to the conditions and regulations by which medical benefit is administered under the panel system of the existing National Insurance Acts. The provisions now made for discharged disabled soldiers and sailors are therefore such as they decline to subscribe to, and your anxious correspondents and others similarly minded need have no fear for their pool, so far, at least, as the members of these bodies are concerned.—I am, etc.,

Edinburgh, Nov. 8th.

JOHN STEVENS.

THE CONFERENCE OF LOCAL MEDICAL AND PANEL COMMITTEES.

SIR,—In the SUPPLEMENT of October 27th I notice a report of the Conference of Representatives of Local Medical and Panel Committees. Curiosity prompted me to see whether the "representatives" of insurance practitioners had as yet awakened to the fact that Manchester and Salford, whose system of administration is entirely and fundamentally different to that of the rest of the country, were absolutely unrepresented on the Insurance Acts Committee. The mere fact that these two towns represent roughly one-twentieth of the entire insured population would seem to give them some little right to representation: but, coupled with the fact that the "Salford scheme" is still worked, and worked successfully there, it

strikes me that no committee that ignored these towns could hope to be considered representative.—I am, etc.,

November 5th.

STANLEY HODGSON,
Captain R.A.M.C.(T.F.).

CEREBRO-SPINAL FEVER AND ITS TREATMENT.

SIR,—Dr. Stewart's letter in your issue of October 6th, 1917, with reference to the treatment of cerebro-spinal fever, is of considerable interest, but I have some little difficulty in appreciating the value of his table.

Dr. Stewart indicates 22 mild cases with 6 deaths, or a mortality of 27 per cent.; and the second series of 24 cases with 10 deaths, or a mortality of 41.6 per cent., is described as mostly composed of mild cases, but surely a case of disease resulting in death cannot be described correctly as mild.

The third group, with a mortality of 41 per cent., composed of all types of cases, does not give a favourable impression of the subcutaneous use of antimeningococcus serum in addition to intrathecal injection.

The final group, composed entirely of severe cases, yields a mortality of 39 per cent., which, by a new and ingenious method in vital statistics, can be made to fall to 17.6 per cent. Dr. Stewart's method of excluding hopeless cases and those over 35 years of age, is not, in my opinion, justifiable, since it brings into play the fatal confusion arising from the personal factor. Two practitioners equally competent, if asked to classify a given case of cerebro-spinal fever as mild, severe, hopeless, etc., may arrive at divergent conclusions. Thus, some of the mild fatal cases enumerated by Dr. Stewart might conceivably be called severe by an equally competent observer.

I may be pardoned if I apply the statistical method introduced by Dr. Stewart to my own series of 41 cases of cerebro-spinal fever treated during 1917.

No. of Cases.	Recoveries.	Deaths.	Mortality.
41	24	17	41.4 per cent.

This is practically the same gross figure as Dr. Stewart's for his second and third groups, but is 2.2 per cent. worse than his final group, and 3.4 per cent. worse than his total mortality for all groups.

I classify my cases as follows:

Group.	Recoveries.	Deaths.	Total.	Percentage of Deaths.
Mild	6	—	6	—
Moderate severity ...	11	—	11	—
Great severity... ..	7	5	12	41.6
Hopeless	—	12	12	100.0
Total	24	17	41	41.4

If we deduct the hopeless group altogether, we get 29 cases with 5 deaths, or a mortality of 17.2 per cent. The only treatment adopted was repeated lumbar puncture, with intrathecal serum injection. The number of punctures varied from 2 to 22 in individual cases, and the amount of serum given from 50 to 250 c.c.m. as a maximum.

Dr. Stewart's statistical method is illegitimate. The use of the word "cured" is to my mind open to the objection that its opposite is "killed." It appears to be less objectionable to use the term "recovery." In that case the opposite term "death" may be taken to represent the triumph of malign forces in spite of the efforts of doctor and patient.—I am, etc.,

A. M. N. PRINGLE, M.B., C.M., D.P.H.,
Medical Officer of Health, Ipswich;
Superintendent, Borough Isolation Hospital.

Ipswich, Oct. 17th.

UNNECESSARY SPECTACLES.

SIR,—Military ophthalmic surgeons are very busy and generally overworked, and I venture to make a suggestion which would, I think, lessen this work to some extent. A considerable saving of time and trouble might be effected by the avoidance of indiscriminate ordering of glasses for hospital patients suffering from headaches or

other subjective symptoms. It is the commonest thing to have sent to the ophthalmic department of military hospitals, from the medical and surgical sides, numerous patients who are there recovering from wounds, dysentery, trench nephritis, or some debilitating illness. Usually these men are of military age, have never worn glasses, and are passing through a temporary period of ill health.

In the usual routine the ophthalmic surgeon examines these cases, discovers some error of refraction, and orders glasses. This is frequently unnecessary; the cases could be treated by ordinary rest to the eyes, the avoidance of all "close" work, and the use of a weak solution of atropine with dark glasses or a shade. I am sure from long experience that this procedure would eliminate the necessity of ordering spectacles in a large percentage of cases, and would lessen the work which is sent to the ophthalmic surgeon, as well as save the country a considerable amount of money, whilst at the same time efficiently treating symptoms which are only temporary.

It may be urged that glasses are given to enable the patient to read and amuse himself by means of books, etc., during his period of convalescence. Men who have been accustomed to much reading might find the treatment suggested irksome, but it is bad policy to encourage these cases to use their eyes, as it is likely to prolong their stay in hospital; it would be much better to put them to some light occupation about the ward and to forbid all reading, writing, etc.

When a man is confined to his bed, he should be advised as to the temporary nature of the trouble and encouraged to amuse himself by other means than by his eyes. I am quite aware that in the treatment of shell shock and allied conditions, the re-education of the soldier by means of needle-work and handicrafts of various sorts is sometimes effective and that the use of the eyes for fine work is part of the means by which this re-education is carried out. These cases, however, do not constitute a large number and might be specially considered. I would urge that glasses should never be ordered for combatant soldiers except for the one purpose of making an inefficient man efficient, or raising him from one category to another. It is quite useless to force a soldier to wear glasses who is unwilling to do so, and even the man who fancies that glasses will help him will discard them as soon as he regains his health.

I think if these points were acted upon by military ophthalmic surgeons much time and money would be saved by obviating the issue of numerous pairs of glasses which are very little used. It is not generally known how enormous an organization the Army Spectacle Department has become, representing thousands of pairs of spectacles provided at great cost of time and money, which are invaluable where they are ordered rightly, but allowing of great waste if sufficient discrimination is not exercised in ordering them. No one can doubt for a moment that glasses should be ordered where they are likely to be of effective use, but every case should be considered from a commonsense point of view by the ophthalmic surgeon, who should not forget that the War Office looks on him as an expert and in his own particular work expects him to make a final decision in most cases.—I am, etc.,

ARTHUR W. ORMOND, Major R.A.M.C.T.,

Surgeon-in-charge, Ophthalmic Department,
London, W., Oct. 13th. 2nd London General Hospital.

THE SENSE OF PROJECTION IN FLYING OFFICERS.

SIR,—In my examination of flying officers and of cadets qualifying as airmen, I have noticed that if a man had a good "sense of projection" he made a good aeronautist; and conversely, that every good flying officer has a well-developed sense of projection. This test seems to me to be almost decisive of a man's fitness for flying. By sense of projection I mean the ordinary test—that a man having looked at a small object, such as the tip of the finger, held at some distance, will afterwards be able quickly and accurately to touch it with the eyes closed.—I am, etc.,

J. C. McWALTER, M.D., LL.D., D.P.H.

THE CURE OF INGUINAL HERNIA.

SIR,—I delayed the publication of my article "The Cure of Inguinal Hernia" for some years, and wrote the article

with some reluctance, for the reasons brought to notice by Mr. Cuning's letter. That is because it is difficult to describe an operation depending upon new technique applied to old principles without appearing to describe the old operation.

A large number of surgeons have done me the honour of watching demonstrations of the operation, and have adopted this method in their practice. The fact that all who have seen the operation agree that it is new to them determined its publication.

The essential principle is that the sac is not dissected out, it is merely incised, and the peritoneum is grasped from within the sac at the level of the internal abdominal ring. Mr. Cuning emphasizes the importance of high ligation in the operation; there is no possibility of low ligation. It may be said that so far as the preparation of the neck of the sac for ligation is concerned in this operation we begin where other operations end.

I am indebted to Mr. Charles Bennett for raising several points which do not appear to have been brought out sufficiently clearly in my article. The finding of the sac would appear to be difficult through so small an incision, but in practice we have not found it so. The coverings of the cord can easily be drawn through the aperture in the external oblique, and once the spermatic fascia is divided the sac is easily found if the wound has been infiltrated with analgesic solution. I use this in liberal quantity, using from one to one and a half syringefuls of a Gray's syringe for the operation.

Treves (*Surgical Anatomy*) draws attention to the fact that the mesentery of the small intestine must be abnormally long if an enterocoele occurs. I think the omentum must be abnormally long to produce an epiplocele. The vast majority of cases coming under my observation contain only omentum.

The retraction of the parietal peritoneum is greater when this method is employed than when the sac is dissected by the ordinary method and we have satisfied ourselves that the neck retracted sufficiently towards the middle line to lie behind the rectus muscle.

Suturing the conjoined transversalis and internal oblique muscles to Poupart's ligament is a simple matter if the lower edge of the aperture in the external oblique is drawn downwards sufficiently to expose Poupart's ligament, and the needle is just passed through Poupart's ligament. The femoral vessels are then not placed in jeopardy. I do not attempt to suture the conjoined tendon beyond the muscular portion which appears in the wound. Cases requiring reconstruction of the inguinal canal, and the very rarely occurring cases of direct hernia are treated by enlarging the incision and the performance of a typical Bassini operation.—I am etc.,

November 8th.

ALFRED J. HULL.

RECURRENCE OF ADENOIDS AND TONSILS.

SIR,—In the JOURNAL of October 20th, p. 539, Dr. J. Lewis Thomas has raised a question in rhinology concerning which I should like to make some comments.

I quite agree with Dr. Thomas that the operation for the removal of enlarged tonsils and post-nasal growths is too often followed in children by little relief owing to the fact that the obstruction has some other cause; Dr. Thomas says that, as far as septum deformity is concerned, very little can be done. With this I do not agree. A deviated septum in a child, provided there is no marked spur, which if present can be removed easily, may be bent into shape with an Asch's blade; and if this is not sufficient, a submucous resection may be done as the child grows older.

The turbinate will probably become reduced in size on its own account, but, if not, a puncture cautery will do this, and in many cases the asthma, if present, will in consequence improve.

If Dr. Thomas takes a series of cases of septum deviation and enlarged turbinate, he will often find on each a small white spot, which in course of time becomes an ulcer, showing that these have been in contact, and is mostly to be observed while the child is asleep.

I have records of many such cases, with improvement and cure of asthma after treatment.—I am, etc.,

Chichester, Oct. 20th.

ARTHUR M. BARFORD.

FRANCE'S SURVIVAL-RATE.

SIR,—The misleading nature of the statement in your useful summary of Professor Richet's report on the "depopulation" of France, that "the excess of births over deaths grows smaller," may be shown by the following table:

French Five-yearly Registers, per 1,000 of Population,

	1875-1882.	1883-1887.	1888-1892.	1893-1897.	1898-1902.	1903-1907.	1908-1912.	1913.
Births	25.0	24.2	22.5	22.3	21.7	20.6	19.4	19.0
Deaths	22.5	22.3	22.2	22.1	20.7	19.6	18.6	17.7
Survival-rate	2.5	1.9	0.3	0.2	1.0	1.0	0.8	1.3

It will be seen that since the period 1888-92 the excess of births over deaths has increased. Moreover, if the survival-rate really depends on the birth-rate, why was the population growing faster when the birth-rate was 19.4 than when it was 22.5? It is surely time it were realized that if a country increases its food supply (home-grown or imported) very slowly, it can only increase its population very slowly—that is, can only have a very low survival-rate, and therefore should have a very low birth-rate.—I am, etc.,

London, S.W., Nov. 3rd.

BINNIE DUNLOP, M.B., Ch.B.

** The statement to which our correspondent takes exception is Professor Richet's ("l'excédent des naissances sur les décès est en France de plus en plus petit"), and does not seem to us misleading. Professor Richet did not say that the decline of the survival-rate was absolutely uniform, but that the trend was downwards—a phenomenon which is sufficiently evident in the figures quoted by Dr. Dunlop. The last sentence of Dr. Dunlop deals with a question which is, in our judgement, a matter of opinion for the discussion of which we cannot at present find space.

LAY RADIOGRAPHERS.

SIR,—I notice from your issue of November 10th that the Medico-Political Committee of the Association has taken up the question of lay radiographers. Let me urge upon the Committee to go a step further and include "medical electricity," as lay bodies, unfortunately supported by some qualified medical men and women, are granting certificates of competency in this subject to lay people, and patients are treated by them. It is absurd to argue that they only treat patients under medical supervision. That is more the exception than the rule; they ought not to be treating patients at all; these methods work out to the great detriment of the public and the profession, and the part played by registered practitioners in aiding and abetting them is deserving of investigation.—I am, etc.,

November 13th.

ELECTRO-THERAPEUTIST.

THE FUTURE OF THE POOR LAW MEDICAL SERVICE.

SIR,—If those engaged in the Poor Law medical service will send me short and decisive replies to the question, "Do you wish the Poor Law medical service to be merged into the present and future general insurance scheme?" I will tabulate the results and make them known.—I am, etc.,

A. WITHERS GREEN,

Honorary Secretary Poor Law Medical Officers' Association, Wardrobe Place, E.C.4.

November 5th.

IT is reported that the health of the French army in Macedonia showed a considerable improvement during the first nine months of this year as compared with last year. The typhoid admission-rate was 1.38 per 1,000, and that of dysentery 7.43. Malaria is still the most serious cause of disability, but even here there has been a notable decline. In August the rate was 23.8 in 1917, as compared with 39.16 in 1916, and in September it was 29 in 1917, as compared with 74.6 in 1916. It is further to be noted that only about one-sixth of the admissions in September were new cases. The improvement is attributed to attention to the sanitation of localities, to the free distribution of mosquito nets, and to a daily dose of quinine, the taking of which is carefully supervised.

Obituary.

EDMUND PRICE, M.B., C.M.E.DIN.,

RADIOLOGIST TO CHALMERS HOSPITAL, EDINBURGH.

By the death of Dr. Edmund Price, which occurred in somewhat tragic circumstances on October 27th, the medical profession in Edinburgh has sustained a loss, and his relations and many friends are mourning to-day the passing away of one who up to the moment of his death appeared to be in his usual vigorous state of health. His may be said to be one of the many instances in these times of a man sacrificing his life at the call of duty, for, though leading a busy professional life in which there was small opportunity for leisure, Dr. Price at the age of 54 joined the 1st Battalion City of Edinburgh Volunteers when it was inaugurated. With them he drilled regularly, sometimes standing guard all night, and it was while attending manoeuvres with his battalion that he met his unexpected and untimely death.

Earnestness of purpose, thoroughness in whatever work he undertook, and unselfishness, were the chief characteristics of the man. His desire when war broke out was to do all he could to help. In addition to his volunteering, he started a course of lectures on ambulance work to the Scottish Women's First Aid Corps, and it was only the day before his death that he was making inquiry as to how he could be of service on the new medical boards that are shortly to be established. There was a quiet dignity about him always tempered by a strong sense of humour. He was a steadfast friend and a delightful companion. In every sense he was a dependable man, and everything he did had the stamp of thoroughness and conscientiousness about it.

Edmund Frederick Tanney Price was the son of Dr. A. G. Price, I.M.S. Four of his brothers were medical men, and he is survived by—besides his widow and a married daughter—three sons, two of whom are qualified and serving in His Majesty's forces, while the third is a medical student. Edmund Price was born in India fifty-five years ago; he received his early education there, and later at Edinburgh University, where he graduated in 1884. For twenty-two years he was well known and highly esteemed as a successful general practitioner in Edinburgh; he obtained a wide knowledge of his profession, and amassed a large amount of clinical material which was to stand him in good stead when he took up x-ray work. This had been attracting his attention for some years, and so fascinated him that in 1906 he determined to specialize in it. His work as a radiographer was quickly recognized to be of a very high order. He was as skilful as he was painstaking, and could always be relied upon to produce the best possible plates. He made a careful study both of the anatomical and clinical aspects of his speciality, and, moreover, took the opportunity, whenever possible, of being present at the operations on patients whom he had x-rayed. By these means he acquired great experience in the interpretation of his plates, so that the profession came to value his opinion and to appreciate the assistance he was able to render them. His caution in not being led into reading more in his plates than was warranted gave him a well-earned reputation as a trustworthy expert witness. With regard to the therapeutical side of his speciality, Dr. Price recognized its limitations, and this attitude served still further to gain for him the confidence of the profession. In 1907 Dr. Price was appointed radiologist to Chalmers Hospital, an appointment he held till the time of his death. He was a member of the Obstetrical Society, the Edinburgh Medico-Chirurgical Society, and the Royal Society of Medicine. Among his contributions to the literature of radiology was a paper published in 1911 on "The diagnosis of urinary calculi by means of the x rays," and an article in the *Edinburgh Medical Journal* in 1914, entitled "The Röntgen ray and bismuth meal method as an aid in the diagnosis of some alimentary diseases." In addition, he contributed the x-ray illustrations of the *Manual of Surgical Anatomy* (Beesley and Johnston).

Dr. Price's life was too fully occupied by his professional work to allow of much time for other outlets for his energetic nature, but two things appealed to him strongly—ambulance work and volunteering. He was, since 1888, a most successful lecturer and examiner under the

St. Andrew's Ambulance Association, and did excellent work in this connexion; while his association with the Volunteers dates back to the time when, as a student, he joined the 4th Battalion Royal Scots. T. J. T.

WILLIAM GRAHAM, M.D.,

MEDICAL SUPERINTENDENT BELFAST DISTRICT ASYLUM.

THE news of the unexpected death of Dr. William Graham, Medical Superintendent of the Belfast District Lunatic Asylum and Medical Officer in Charge of the War Hospital, Belfast, was received with the greatest regret by all who knew him. He was the personification of strength and energy; nothing seemed to tire him; the rate he walked at and the distances he covered were the envy of many a young man. He kept himself in the best condition, physical and mental. About three weeks ago, while passing through the village of Newtonbreda, returning from town to the asylum, his ankle suddenly bent and he fell heavily and fractured the upper part of the femur. Three days before his death there were signs of an embolus; these recurred on November 5th, and he died suddenly on the night of that day. He was about 56 years of age.

Dr. Graham graduated in the old Royal University in 1882. He studied mental diseases in London and on the Continent, and was appointed assistant medical officer in the Belfast Lunatic Asylum. In 1884 he was elected resident medical superintendent of the County Armagh Asylum, and was then the youngest occupant of such a post in Ireland. In 1896 he succeeded the late Dr. Merrick as resident medical superintendent of the Belfast Lunatic Asylum, and many memorable and important reforms marked his tenure of office. He had a fine humanitarian spirit, had deep sympathy with the insane, and was endowed with great powers of organization; he insisted on a high standard of efficiency; much liberty was allowed the patient, fresh air and outdoor work; consequently very little bodily restraint was ever needed. Largely to his initiative was due the establishment of the villa colony system at Purdysburn; the old asylum buildings on the Grosvenor Road—built in 1829—were out of date, and congested; the large demesne of Purdysburn, about five miles from the city, was purchased; it consisted of 295 acres, and was subsequently enlarged by the acquisition of adjacent grounds. As each villa was completed, a batch of patients was removed to the new site, where the utmost liberty compatible with their safety was allowed, and congenial occupation assigned. The institution is not yet completed, and further work has been arrested by the war. When the Grosvenor Road buildings were taken over by the military authorities as an ear hospital, he was given control with the rank of lieutenant-colonel.

Dr. Graham's annual reports were always welcomed by the daily newspapers, and large quotations on the general subject of insanity and its causes, on its prevention, on the necessity of healthy mental culture and mental cleanliness, appeared in their columns. He pointed out the dangers and errors of our education and of our social fabric in clear and incisive terms; these reports were intended to have and had an educative effect on the public, which tables of statistics never achieve.

His favourite relaxation was hunting, and his colours were victorious in more than one local race meeting. He is survived by his widow, with whom the deepest sympathy is felt, and two brothers, one of whom is Dr. Samuel Graham, medical superintendent of the County Antrim Asylum.

NEIL OMAN, M.D. EDIN.,

PORT SURGEON, GIBRALTAR.

At Gibraltar, on October 8th, Dr. Neil Oman, the president of the local Branch of the British Medical Association, passed away at the advanced age of 82. A native of Wick, he studied at Edinburgh University, and after a brilliant course there graduated M.B., C.M. in 1865. Subsequently he was class assistant to Sir J. Y. Simpson, and was intimately associated with the early triumphs of chloroform anaesthesia. He took the M.D. in 1871, and remained in Scotland practising his profession till 1879, when he removed to Malta. During the course of ten busy years there he occupied a foremost place in the life of the island, working with untiring energy during epidemics of

diphtheria and cholera, initiating and maintaining classes for the St. John Ambulance, and yet finding time to interest himself in music, painting, and etching.

In 1889 he began practice in Gibraltar, and continued to work there until three months ago. At the time of his death he held the appointment of port surgeon, but he had previously held other appointments in the colony. He was beloved by his patients and held in the highest esteem by the whole community. His generosity to the poor was great, but so quietly was his help afforded that its extent will never be fully known.

With Dr. Oman has passed away an interesting link with the past and a straightforward practitioner of the best type.

DR. CLEMENT MICHAEL ROGERSON, of Huddersfield, died on November 3rd from blood poisoning, which followed the pricking of his right thumb while repairing the hood of his motor car. He was 50 years of age, and was the son of the late Mr. Rogerson, chemist, of Bradford. He was educated at the Bradford Grammar School, where he secured several scholarships, and graduated M.B. Lond. with honours in 1892, and M.D. three years later. After filling the posts of house-physician and assistant laryngologist at the Leeds General Infirmary, he settled in practice at Huddersfield. He was a member of the Huddersfield Division of the British Medical Association, and leaves a widow, one son, and a daughter.

DR. GEORGE FREDERICK ODHAMS died at Norwich on October 26th, aged 56. He was educated at the University of Edinburgh and Guy's Hospital Medical School; he graduated M.B., C.M. Edin. in 1887, and M.D. three years later. After serving as house-physician to the Edinburgh Royal Infirmary and as assistant to the professor of clinical medicine in the university, he joined Mr. F. C. Bailey of Norwich as partner, and on the latter's death succeeded to the practice; in recent years he was in partnership with Dr. Nutman. He held the offices of district medical officer of the Norwich Union, surgeon to the Institute for the Indigent Blind, and consulting surgeon to the Norwich Lying-in Charity. He was elected a member of the Norwich Town Council in 1902 and served on various committees connected therewith. He was appointed a Justice of the Peace in 1909. He was a member of the Norwich Division of the British Medical Association, and was president of the Norwich Medical War Committee. He is survived by his widow and a daughter.

DR. ALPHONSE BOISSARD, a well-known obstetrician of Paris, who died on September 7th, was born in 1852. He gained the post of interne in 1879, was *chef de clinique* under Pinard, and was appointed accoucheur to the hospitals in 1891. After serving as assistant to Budin at the Maternité he became obstetric physician to the Tenon Hospital in 1898, afterwards passing in a similar capacity to the Saint Louis, and later to the Lariboisière. He was the author of memoirs on induced labour, rapid forced dilatation of the cervix, emptying the uterus in cases of retention of the dead fetus, dystocia, fetal monstrosities, treatment of puerperal infection by fixation abscess, and many other subjects. He made researches on the formation of the sexes and telephony, and took a practical interest in puericulture. He was president of the Paris Obstetrical Society in 1911.

DR. WALTER FOWLER, son of the late Dr. Robert Fowler of London, died at Bendigo, Victoria, Australia, on July 26th, aged 59. He won the Tancred studentship at Gonville and Caius College, Cambridge, about 1876, and subsequently joined Guy's Hospital Medical School. He took the diplomas of M.R.C.S. Eng. and L.S.A. in 1883, became F.R.C.S. in the following year, and graduated M.B., B.C. Camb. in 1885. He was house-surgeon at Guy's Hospital in 1883 and commenced practice in Birmingham in 1885, where he held an out-patient surgical appointment at the Queen's Hospital. On the death of his father in 1886 he succeeded to his practice in Bishopsgate Street, removing subsequently to Finsbury Pavement. A few years later, owing to ill health, he migrated with his wife and two children to Australia. After nine years' private practice in Echuca, Victoria, he became resident medical

officer to the Bendigo Hospital, where he was responsible for a large amount of surgical work and was held in high esteem as a surgeon. Failing health compelled his retirement in 1912. He leaves a widow, two sons, and a daughter.

DEPUTY SURGEON-GENERAL JOHN DAVIDGE, Army Medical Staff (retired), died at Hove on October 23rd, aged 86. After taking the diploma of L.R.C.S.I., he entered the army as an assistant surgeon on August 5th, 1858, nearly sixty years ago. He became surgeon on August 5th, 1870, surgeon-major on March 1st, 1873, and retired as brigade surgeon, with an honorary step on retirement, on October 4th, 1886. He served on the North-east Frontier of India, in the Bhutan campaign of 1865-66, receiving the medal and clasp, and in Egypt in 1882, receiving the medal and the Khedive's bronze star.

MAJOR-GENERAL T. ROSATI, surgeon-general of the Italian navy, recently died at the age of 57. He was formerly professor of diseases of the ear and throat in the University of Naples.

Universities and Colleges.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on October 24th.

Examiners.—The following were appointed examiners for the second examination for medical degrees, Part II, in the session 1917-18: Anatomy: Professor J. E. S. Frazer (St. Mary's Hospital Medical School), together with the external examiner, Professor R. W. Reid (chairman). Pharmacology: Dr. E. Mellanby (King's College for Women), together with the external examiner, Professor R. B. Wild (chairman). Physiology: Dr. J. Mellanby (St. Thomas's Hospital Medical School), together with the external examiner, Professor D. N. Paton (chairman).

Regulations in Medicine for Internal Students (War).—The regulations (September, 1917) were amended to provide that during the continuance of the war internal students who at the first examination for medical degrees in December complete that examination by passing in the subject in which they have previously been referred, and students who, having obtained exemption in two subjects of the first examination for medical degrees in December, will be admitted to the second examination for medical degrees, Part I, in the following March, provided that they shall, after the date of reference or exemption, have attended as internal students for the prescribed number of hours courses of lectures and practical work for that examination.

Committees.—Sir Frederick Taylor has been elected chairman of the Committee of Medical Members of the Senate, and Sir David Ferrier chairman of the Laboratory Committee.

ST. THOMAS'S HOSPITAL.

The Grainger Testimonial Prize of 30 guineas at St. Thomas's Hospital, given for a series of specimens illustrative of recent anatomical and physiological research, has been awarded to R. S. Foss.

UNIVERSITY OF GLASGOW.

At a graduation ceremony held in the Randolph Hall of the University on November 10th, Principal Sir Donald MacAlister conferred the following medical degrees:

M.D.—R. T. Leiper, J. L. Boyd, W. H. McKinstry, D. Smith, S. H. Bennett.

¹ With honours. ² With commendation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary Council was held on November 8th, when Colonel Charters J. Symonds, A.M.S., Vice-President, was in the chair.

Diplomas of membership were granted to eighty-seven candidates found qualified at the recent examinations.

Sir Herbert Waterhouse was elected to represent the College on the Managing Committee of the Schiff Home of Recovery and Sir George Makins and Sir John Bland-Sutton to represent the College on the Board of Scientific Societies.

CONJOINT BOARD IN ENGLAND.

The diplomas of L.R.C.P. and M.R.C.S. have been conferred upon the following candidates who have passed the final examination:

Esawy Ahmed, E. B. Ash, Ruth Balfour, N. A. H. Barlow, G. E. Birkett, J. A. Birrell, A. Blackstock, Numa Sylla Bonard, G. Bourne, J. W. Brash, A. Bulleid, H. B. Bullen, F. Cameron, W. A. Clements, B. S. Collings, J. D. Constantin, G. W. Coombes, J. R. Cox, E. H. T. Cummings, D. R. Curnock, W. L. Dandridge, Hari Das, T. Davies, L. P. de Abrew, B. G. Derry, W. L. de Silva, J. D. Dimock, J. S. Ellis, M. W. Giffin, Satyapriya Ghosh, E. A. Gibb, J. C. Gio, C. H. Gilmour, L. C. Goumet, Lilian M. Griffiths, D. V. Halstead, E. C. Hinde, W. O. Holst, P. G. Horsburgh, R. Hunter, J. W. D. Hyde, C. V. Isard, T. G. James, N. K. Jenkins, M. H. Jupe, Nai Kamchorn, D. J. A.

Lewis, Emily C. Lewis, T. P. Lloyd, Alice L. Lloyd-Williams, A. V. Lopes, J. G. McCann, J. S. Matthews, L. C. Moore, A. H. Morris, W. P. Nelson, J. W. McK. Nichol, W. D. Nicol, F. C. Odling, D. F. Pantou, C. S. Parker, R. W. Payne, C. F. Rainer, H. Ratnarajah, F. N. Reynolds, H. E. Rhodes, Helen Roth, H. B. Russell, Khan Sahib, J. J. Savage, S. C. Shaw, C. Shaw-Crisp, C. E. A. Shepherd, Charlotte A. Shields, M. O. Simpson, Rani Sinha, B. L. Skeggs, R. C. W. Staley, H. Taylor, H. G. Taylor, O. S. Thompson, J. F. Twort, P. Ward, C. H. Warner, A. W. Wells, A. Winfield, K. M. C. Woodruff, E. B. Woolf, I. H. Zortman.

Medical News.

DR. CARREL being detained in America by official duties, the Harben lectures he was to have delivered at the end of this month have been postponed.

SIR WILLIAM MACEWEN, C.B., Dr. Robert Kennedy, and Dr. John Macintyre have been appointed Deputy Lieutenants of the county of the City of Glasgow.

SIR ARTHUR NEWSHOLME will give the Lady Priestley Memorial Lecture of the National Health Society on Wednesday next at 3 p.m., at the house of the Royal Society of Medicine. The subject is "The child and the home"; Mr. Hayes Fisher will preside.

At the quarterly meeting of the Medico-Psychological Association on Tuesday, November 27th, at 3 p.m., at the rooms of the Medical Society of London, Chandos Street, Cavendish Square, Drs. David Orr and R. G. Rows will contribute a paper, illustrated by lantern slides, on experimental toxic-infections of the central nervous system.

CAPTAIN KEYWORTH has brought out a third edition of his little pamphlet *Easy Italian and How to Pronounce It*, in the expectation that it will be found useful by British troops now in Italy. It contains a short vocabulary and a few simple phrases. It is published (price 3d.) by Combridges, 56, Church Road, Hove, and can be obtained at many of the principal stores and shops in London.

ALDERMAN A. MACGREGOR SINCLAIR, M.B., C.M.Aberd., Surgeon to the Victoria Hospital, Burnley, has been elected Mayor of Burnley for the third year in succession. No previous mayor of Burnley has served for more than two years in succession. Dr. MacGregor Sinclair has the confidence of all parties. His work as chairman of the tribunal has been arduous and has been carried out faithfully and justly to all concerned.

THE Royal Society has awarded the Copley medal to Dr. E. Roux, Director of the Pasteur Institute, Paris, for his services to bacteriology and as a pioneer in serum-therapy, the Buchanan medal to Sir Almroth Wright for his contributions to preventive medicine, and the Hughes medal to Professor C. G. Barkla for his researches in x-ray radiation.

THE new scheme for voluntary rations contains the statement that the consumption of milk and cheese should be restricted as far as possible, these foods being reserved for persons for whom they are indispensable. As it is difficult to think of a person for whom cheese is indispensable, it may be assumed that the last clause has in view the need of children for milk. In Paris steps are being taken to ensure that children under three years of age and the sick should have preference in obtaining milk. Persons desiring to take advantage of the system must obtain a ticket and hand it in with a medical certificate at the mayor's office, when the quantity of milk to be delivered daily will be fixed.

As already announced, Dr. Christopher Addison, Minister of Reconstruction, will deliver an address on "Health problems and reconstruction," at the Central Hall, Westminster, on Saturday, November 24th, at 12 noon. Mr. H. Kingsley Wood, L.C.C. (Chairman, Faculty of Insurance), will be in the chair, and among those who intend to be present are Dr. Alfred Cox, Dr. H. B. Brackenbury, and Messrs. W. A. Appleton, C.B.E. (General Federation of Trade Unions), Edwin Potts, L.L.B. (National Association of Insurance Committees), W. Edwards (Refuge Assurance Co.), William Marlow (Ancient Order of Foresters), C. Tuckfield (National Deposit), F. Coysh (Holloway Union), and P. Rockliff (London Insurance Committee). Tickets can be obtained free on application to 3 and 4, Sicilian House, Southampton Row, W.C.1; 112, City Road, E.C.1, or to the office of this JOURNAL.

DURING their visit to Bath on November 9th, the King and Queen made a brief inspection of the Combe Park War Hospital, which now has accommodation for 1,200 patients. The principal bathing establishments were also visited, and Their Majesties were shown some of the methods of treatment, more especially those which are applicable to wounded and invalided soldiers. At the outbreak of war the Bath Corporation offered the Government free

treatment for all wounded and invalided officers and men sent by the naval and military authorities. This offer was accepted, and thousands of the military cases have been treated without interfering with the accommodation for civilians. Including hydrotherapeutic measures at the Royal Mineral Water Hospital, which has admitted 2,275 military patients, the contribution of the hot springs of Bath towards the cure and relief of soldiers of all ranks consists of treatments numbering nearly 160,000.

J. L. BAKER and H. F. E. Hulton reported to a recent meeting of the Society of Public Analysts the result of the analysis of peeled chestnuts and peeled acorns. The percentage of starch in three specimens of chestnuts averaged 44.2, but in a fourth specimen was as low as 21.9. The amount of cane sugar varied from 8.1 to 17.5, possibly in relation to the degree of ripeness. Diastase present behaved like the diastase of an ungerminated cereal. The percentage of starch in two specimens of peeled acorns was 57.1 and 55.7 respectively. There was very little cane sugar in either specimen, but some reducing sugars. No diastase could be found in the acorn either before or after germination.

THE fifteenth annual report of the Gordon Memorial College at Khartoum, for 1916, states that the research work of the college, which is one of its most valuable features, has, unfortunately, had to be curtailed, and the staff has for the time being confined its energies almost solely to matters of immediate practical application to Sudan problems. The paramount claims of various war services upon the staff, together with the growing shortage in the supply of reagents and other chemicals, have brought many branches of work practically to a standstill. Dr. Chalmers, in his report on the work of the Wellcome Tropical Research Laboratories, expresses the hope that some arrangement will be made for the resumption of the publication of full reports on the lines of those issued by Dr. Andrew Balfour. The research work of the bacteriological section has been maintained, but the routine examinations were many less than in 1915, when there was an epidemic of cerebro-spinal meningitis. Work on streptococcal infections included an inquiry into the puerperal fevers of the Sudan.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology*, Westrand, London; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

HOMES FOR INCURABLES.

A CONSIDERABLE number of requests are received for the publication of inquiries for homes for persons suffering from various chronic crippling conditions, especially chronic nervous and rheumatic disorders. Two recent inquiries refer to a woman, aged 23, able to pay 5s. a week, and to a young man suffering from specific cerebro-spinal disease, able to do light out-of-door work.

The publication of such requests, often accompanied by a description of the symptoms, occupies space which can ill be spared, very rarely elicits any reply, seldom or never any satisfactory reply. The accommodation provided in homes for incurables and other charitable institutions is limited and admission to the large institutions is usually by election (subscribers' votes), with all that that entails. Other smaller institutions admit by payment. These are mostly for women. If the annual income available is sufficient, the best course seems to be to set up the sufferer in a local cottage with an attendant. If only a small weekly payment can be provided, a respectable cottager may be found in the neighbourhood willing to take the case. The clergy and district visitors are usually willing to exercise some supervision. If the patient has no resources, there remains only the Poor Law infirmary or workhouse.

TREATMENT OF PEDICULOSIS PUBIS.

MAJOR WALTER BARTY, C.A.M.C., writes to condemn the treatment of pediculosis pubis by shaving and application of mercurial ointments. The discomfort of the shaving, he says, is great, particularly when the armpits and hairy parts of the chest, arms, and legs, are covered with parasites, as often happens with patients infected from blankets. He recommends in its place the application to all parts of the body of petrol (gasoline) which he has seen employed for years. It gives instant relief and appears to destroy the lice and the nits almost immediately. It causes no discomfort and the odour quickly disappears. When petrol is not available, paraffin (coal-oil or kerosene) may be employed in the same manner. This, however, causes a burning sensation and may even take the skin off in the fork and over the scrotum so that the excess should be quickly wiped off or bathed off with soap and warm water. He adds that the usual precautions must be taken with the clothing, but where ordinary sterilization is impossible the free use in them of petrol or paraffin will be found quite effective.

POISONING BY LABURNUM SEEDS.

DR. G. F. SYDENHAM (Dulverton, Somerset) writes: I saw two cases of poisoning by the seeds of laburnum on October 22nd at 7 p.m. in children aged respectively 5 and 3. They had been very sick and vomited up both husk and berry. They were unconscious, with very dilated pupils, which did not act to light. The temperature was not raised; the pulse, so far as it could be counted, was very feeble. The heart sounds were feeble. There were no convulsions and no diarrhoea. The treatment was expectant. Both children were comparatively well next morning.

In this connexion I may say I have a curious freak in my garden. Twenty years ago I planted a small bush of lilac laburnum. This year the tree as it now is had three distinct coloured flowers on it—lilac, a deep purple, and yellow. The different colours were on separate branches. Each branch was a distinct colour.

According to Wynter Blyth's *Poisons: Their Effects and Detection*, the active principle is an alkaloid (cytisine) which occurs in many plants belonging to the Leguminosae, but is best obtained from the seeds of laburnum. The same alkaloid, or one nearly allied to it, occurs in the flowers, bark, wood, and root of laburnum (*Cytisus laburnum*). The symptoms of poisoning by cytisine are mainly referable to the gastro-intestinal tract, and consist of acute pain in the stomach, vomiting, and diarrhoea. In 155 cases, 120 of which were instances of accidental poisoning of children, collected from the medical literature by Falck, there were only four deaths—2.6 per cent. The symptoms produced by eating the root, which, like other parts of the tree, is sweet, are more severe, vomiting being followed by narcosis, convulsive movements of the limbs, and dilatation of the pupils.

AN INQUEST ON A LEG.

LIEUTENANT W. A. MURRAY, M.B., D.T.M., R.A.M.C. (London), writes: The note by Mr. Norman Porritt in your issue of October 13th reminds me of an incident that occurred to me last year when I was acting as civil surgeon of Chittagong, Bengal. I received a notice from the police to perform a *post-mortem* examination, and on going to the mortuary found a solitary leg on the table. A glance was enough to show that it had been amputated by a surgeon, and on further examination I recognized it as one I had myself amputated in hospital the day before for disease (I forget now what). The explanation was this: Amputated limbs, tumours, and other such products of hospital activity were put into a receptacle which was emptied and the contents removed daily by the municipal sweepers, to be taken with the night-soil to be dug in at the trenching ground outside the town. On the day in question a heavy rainstorm had occurred while the sweepers were on their way to the trenching ground, so, in order to save themselves further trouble, they had emptied their carts into the nearest ditch and made off; the night-soil and other matters had been washed away by the heavy rain, but the leg being heavy had remained and been found by the police, who solemnly sent it to the mortuary for examination. The story is interesting or amusing according to the way it is regarded.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postea restante* letters addressed either in initials or numbers.

An Address

ON

MODERN ANTISEPTICS.

DELIVERED AT A MEETING OF THE HUNTERIAN SOCIETY
ON NOVEMBER 7TH, 1917.

BY

LIEUT.-COLONEL SIR ALFRED PEARCE GOULD,
R.C.V.O.

THE great conceptions of the early workers with antiseptics were: (1) That all wound diseases are due to infection with living organisms—at first always spoken of as "germs," the "germs of disease." (2) That these "germs" gain access to a wound from without, and chiefly through the air. (3) That these "germs" can be killed by treatment with sufficiently powerful antiseptics, and if and when this is done, healing of a wound proceeds without interruption. The aim of these early antiseptic surgeons was to prevent infection of wounds, and the early triumphs of antiseptic surgery were gained in the prevention of those terrible complications which had up to that time been the bane of surgery.

This prevention of wound infection marked, of course, an enormous advance in surgical knowledge and practice. By careful antiseptic measures—and the same is true of "aseptic surgery"—the healing of wounds in civil practice has for years proceeded with almost unbroken uniformity. Secondary haemorrhage has become a surgical rarity, and wounds have healed without complications under conditions which demonstrated the futility of attributing the previously frequent disasters to "reaction," or to "hospitalism."

The demonstration that wound complications are the result of infection from without and can be prevented by appropriate germicidal measures was, then, the first great contribution of antiseptic surgery, and a splendid contribution it has been!

Since the war, however, surgeons have been called upon to treat, in unprecedented numbers, wounds already gravely infected, and they have been faced, as never before, with the problem of the cure of infected wounds. It is not surprising that the dressings employed as part of the preventive treatment of surgical and recent wounds have proved ineffectual in dealing with wounds already deeply infected. Surgeons experiencing this and yet convinced of the value of antiseptic treatment and of the accuracy of the observations upon which it rests, have sought to add to the efficiency of their antiseptic measures by using in the first place more powerful germicides, and then by using these germicides in a more efficient manner. To this they have added in certain cases the use of serums and vaccines.

But the mere recovery of the patient and the healing of the wound that has been infected is only part of the aim of the surgeon. Knowing as he does that by the use of antiseptics in such a way as to prevent the development of pathogenic organisms in a wound he can ensure rapid and unchecked healing of wounds, he necessarily has asked himself whether antiseptics cannot eradicate these same organisms from tissues in which they are already growing, and leave the tissues free to heal in the same painless, feverless, and rapid way as when no infection has occurred. This is the problem presented to-day to the antiseptic surgeon.

THE CURE OF INFECTED WOUNDS.

Just as the early antiseptic surgical work followed and was based upon certain laboratory experiments, especially those of Pasteur on fermentation, so we have demonstrations—experiments if you like—that have a very direct bearing upon the modern antiseptic problem, which is the cure of already infected wounds. The experiments cannot be a matter of test tubes or flasks, they must be carried out in living animal tissues already the seat of infection. An acute abscess allowed to burst, or merely opened by the surgeon, and not "treated" in any other way, is such an experiment. Up to the moment of letting out the pus, a bacterial invasion runs riot in the tissues forming the so-called "abscess wall," and it is this area of the entire lesion that is the source of the patient's pain, fever and danger. Immediately the pus is evacuated the whole picture changes—the infection is arrested, the invaded tissues are sterilized, and, given certain favourable con-

ditions, the damage that has been done is quickly and completely repaired. This result is brought about by the application to the infected tissue of a highly cellular fluid, locally produced, which has a germicidal effect—what I would for the present purpose call an "autogenous antiseptic"—aided by the evacuation of the mass of liquefied tissue, dead leucocytes, and living, moribund, and dead bacteria, which we call pus. Whenever we see an acute abscess burst and heal very rapidly, we are sure that certain particular agents have contributed to that result: (1) the application to every part of the invaded tissue of a potent autogenous germicide; (2) the preservation of the living tissues from all injury, and (3) the evacuation of all dead matter—the pus. There are, of course, many similar experiments performed for us, bearing upon the problem of the cure of infected tissues, but the life-history of an acute abscess is as instructive as any, and is very familiar.

"THE AUTOGENOUS ANTISEPTIC."

The problem of modern antiseptics is first of all how best to sterilize an already deeply invaded tissue, and I submit that the solution of that problem will probably be found in a close imitation of nature's method of effecting this object. But before referring to some of the features of "natural antiseptics," we must notice two points: the first is, that nature plays her healing part in every case of tissue infection, and that whatever additional means the surgeon may use, he is always backed up by nature, and must never think that success depends wholly upon his efforts. In these cases the *vis medicatrix naturae* is very real, it can never be dispensed with, and happily cannot be put out of action, even if the surgeon wished it.

Then we have to ask the question whether this "autogenous antiseptic" is enough for our purpose, and whether having cleansed a wound and possibly provided means of drainage, it will suffice to accomplish all else that is needed to sterilize an infected wound. I think the answer to that question should be in the negative. Great and beneficent as is nature's germicidal power, experience shows that it is often slow and laborious, and is incapable of effecting that rapid repair of wounds which is most urgently desirable. I say this because there are surgeons who treat gravely infected wounds by so-called "boric fomentations," made by soaking boric lint in boiling water and wringing out the fluid. By this means the acid is dissolved out of the lint, and a dressing which at its best is possessed of but feeble antiseptic powers has its germicide carefully removed, and the wet "boric lint" is merely a hot and moist aseptic application. As such it may be of value in stimulating the flow of the natural antiseptic, and in soothing the irritated nerves, but it must not be regarded as an external or heterogeneous antiseptic dressing.

Taking the natural method of sterilizing infected wounds as our model, we learn that the surgeon should—

1. Use an efficient germicide; of these he has several from which to choose.

2. He should use an antiseptic which is innocuous to living tissues. It is opposed to "natural antiseptics" to use a caustic antiseptic such as pure carbolic acid, or a substance poisonous when absorbed into the blood stream, like the various salts of mercury. No doubt we have all seen good results in cases in which either of these classes of antiseptics has been used, but such treatment is certainly opposed to the antiseptic process employed by nature, and requires some special condition to justify it.

3. Next the efficient but harmless antiseptic should be applied continuously to the entire infected surface or tissue. How often surgeons have done little more than mix some antiseptic with the discharge after it has escaped from a wound, or have applied an efficient antiseptic for a few minutes once or twice in twenty-four hours! We need to visualize as far as we can in every case the actually invaded tissues, and to secure that our antiseptic finds its way to every spot in the germ-laden tissues.

4. Another lesson is the necessity for the rapid removal from the wound of all dead and dying tissue, all used-up antiseptic, dead bacteria, and tissue detritus. This, too, should be effected early, and should be neither intermittent nor dependent upon such violent measures as strong irrigation or firm pressure.

5. If the surgeon does all this, he will, I fear, fall short of the natural process in one important particular, in which

So far as I know we have at present no means of imitating it. Nature applies her antiseptic to an invaded tissue from within out; she assails first and with most vigour the van of the invading host—the most vigorous and active of the rapidly multiplying bacteria. The surgeon, on the other hand, seems to be tied down to attacking the invading host from the rear, in the hope that his antiseptic will soak in so far as to overtake the advanced lines of the invaders.

MODERN ANTISEPTICS.

If these are the lessons we learn from nature's method of curing an infected tissue, what is the practical application of them in our modern antiseptic treatments? I think these treatments may be conveniently put into three categories. There is, first of all, the use of an antiseptic which is at once very highly germicidal and innocuous to human tissues; of these flavine may be regarded as an excellent example. There is, secondly, the frequent gentle application of a potent germicide to the whole surface of a wound until the discharge from the wound is clinically sterile, and then the surgical closure of the wound. And, lastly, the immediate closure of the wound with a sufficient amount of reliable germicide within it to sterilize the whole of the infected area of tissue.

The first—the use of such antiseptic as brilliant green and flavine—calls for no special comment just now. These drugs are certainly good antiseptics, and are a valuable addition to the surgeon's armamentarium, but their use, so far as I can see, does not introduce any new method or new principle of treatment; it is merely alleged to be attended with more success than is commonly met with when other antiseptics are used in the same way.

The second method is that introduced by Carrel. The third is associated with the name of Professor Morison. These are new methods of treatment, and as such deserve special notice.

Carrel's Method.

I had the advantage in April last of seeing, along with some other British surgeons, the Carrel treatment of wounds as carried out in his hospital at Compiègne, and by M. Tuffier and M. Clutro in Paris. The results were certainly most striking. I saw whole series of cases of compound fractures—not one or two selected cases—healing well and without a single drop of pus. I was impressed as much as anything with an experience on my first visit to M. Tuffier's military hospital in Paris. Along one whole side of a ward each bed was occupied with a case of chronic empyema, all the cases but two having followed upon gunshot wounds of the chest, and all of them having lasted for many months before coming under M. Tuffier's care. The treatment had consisted in making a free opening in a dependent part of the cavity and then in applying Dakin's fluid by Carrel's method, as far as possible, to the whole surface of the cavity. A daily enumeration of the bacteria in a smear of the discharge was made, and as soon as the number had fallen to one in a field, or less, and had remained at this level for three consecutive days, the skin edges of the wound had been raised from the chest wall and united, quite regardless of the presence or size of any pneumothorax or unobliterated portion of the pleural cavity so shut in. In every case we saw—and we saw all in the ward—the wound was healed and the man was well. The aim of the Carrel treatment is to obtain "clinical sterilization" of the wound and then to close the wound and secure union of the applied surfaces. It is laid down as a canon that no wound that has been infected should be closed until it has been proved to be practically sterile by thrice-repeated bacteriological examination.

I cannot give any better evidence of the confidence of the surgeons in Paris who are carrying out this treatment with scrupulous precision, than to quote the notice placed in a conspicuous position in each of M. Tuffier's military wards. It reads: "Tout blessé qui suppose a le droit d'en demander la raison à son chirurgien." Or I can quote M. Tuffier's own words to me: "I can sterilize any wound by this treatment."

As our report on this method of treatment was published in the *BRITISH MEDICAL JOURNAL* for November 3rd (p. 597), I need now only say:

1. That the germicidal effect is produced by the two-hourly bathing of the whole area of the wound with a potent antiseptic, such as Dakin's solution or eusol. This

can only be accomplished when the tubes are carefully placed and distributed. It is not enough simply to place one or more tubes in a wound, and to turn a stream of antiseptic through them from time to time. The method of treatment must be carried out exactly and with scrupulous attention to detail, and by the surgeon himself, if the best results are to be obtained. It must not be handed over to a nurse or any unskilled attendant. It is necessary to say this, as I know the treatment has been condemned on the result of its use under conditions other than those insisted on by M. Carrel.

2. The cleansing of the wound is effected largely by the flow of fluid from the deeper parts of the wound towards the outer dressing; this, too, will not be effected unless the antiseptic is distributed over every part of the wound surface.

3. When one has got into the routine, and if provided with a sufficient number of trained nurses, the treatment is not complicated or difficult; indeed, it lessens the nurses' work as compared with that entailed in some other treatments.

4. Closure of the wound is not attended with danger if it is postponed until the discharge from it is demonstrably free from organisms, or very nearly so.

Morison's Method.

The Morison treatment is quite different in method. It consists in first of all removing from the surface of the wound as completely as possible all dead and dying tissue and tissue detritus, all accumulations of discharge and of bacteria as well as of blood clot and all other "foreign" matter. This is done by vigorous friction of every part of the wound, followed by "drying" of the wound by spirit. An antiseptic paste (bipp) is then smeared over the entire wound surface and rubbed in, and then at once the wound is closed with sutures and covered with a dressing that is not disturbed for twelve days or so, when it is expected that the wound will be found healed or healing well.

The Morison treatment of wounds is, in my opinion, the highest attainment yet achieved. Deliberately to sew up a wound known to be gravely infected after a single "treatment" and trust to sterilization being effected by the enclosed antiseptic is a bold procedure which when successful—as it is in Professor Morison's hands—well merits the description of "brilliant." I have not been able to see Professor Morison's cases, but I have read of them and heard of them from eye-witnesses, and I can have no doubt of the results—the brilliant results—which are obtained. The technique is very definite and must be carried out with great care. As in Carrel's method, it is twofold. On the one hand the dead and dying material is most thoroughly removed by vigorous friction. Then a potent antiseptic (bipp) is most carefully applied to every part of the infected surface in sufficient but not excessive quantity.

Professor Morison's treatment cannot be summed up in the one word "bipp" any more than Carrel's can in the one word "tube." Each method of treatment depends for success upon a very careful technique, and it must be carried out in every detail with scrupulous care. Let me repeat, that the aim of each is the same—the sterilization of the previously infected wound and its closure so as to secure rapid union with the minimum of scar tissue. Carrel proceeds in stages—first the sterilization, and only after that has been attained does he suture the wound. Morison combines them in one "treatment" with far less labour and less cost in dressings.

It is not for me to pass judgement upon these methods; I would merely express my belief that if the task of modern antiseptics is to "cure" and quickly heal infected wounds, there is good reason to believe that we are now possessed of means by which that task can be accomplished. If we look back with just pride upon the triumph of Lister and his associates in rendering possible and commonplace the prevention of wound complications, we are entitled to be just as proud of the further surgical triumph by which infected wounds can be sterilized and healed as if no infection had ever occurred. Those of us who remember the opposition to Lister's early teaching and practice recognize that it sprang not from jealousy or indifference, but from a failure to entertain and aim at a higher standard of surgical success than his critics were

already familiar with. The surgeon's "works" were limited and conditioned by his "faith." It was because Lister "dreamed dreams" that he worked away with carbolic putty. And so it will be to-day. We have all been familiar with the slow healing by granulation of these sorely infected wounds and with the resulting extensive scarring. The teaching of "modern antiseptics" demands not only the practice of new technique, it calls perhaps even more for the raising of a new standard of surgical work, for new faith, for the visualizing of new possibilities, and success will only come to those who have an enlarged and brighter hope.

FURTHER OBSERVATIONS ON THE RESULTS OF BLOOD TRANSFUSION IN WAR SURGERY,

WITH SPECIAL REFERENCE TO THE RESULTS IN
PRIMARY HAEMORRHAGE.

BY

L. BRUCE ROBERTSON, B.A., M.B. TORONTO,
MAJOR C.A.M.C.

With a Note by

C. GORDON WATSON, C.M.G., F.R.C.S., COLONEL A.M.S.,
CONSULTING SURGEON B.E.F.

In a previous paper¹ the results of blood transfusion in a few cases of secondary haemorrhage were given, with a description of the Lindeman syringe-cannula method.² Since that time opportunity has arisen of extending its application to cases of severe primary haemorrhage (accompanied by shock). The results of these cases are presented in this paper. In four cases of this series the citrate method was used; one case was done with the Unger two-way stopcock, the remainder by the Lindeman syringe-cannula method. The results have shown:

1. That certain cases heretofore considered as inoperable, and others as exceedingly bad surgical risks, may often be revived to a degree which not only permits of radical operative measures, but ensures a good prospect of ultimate recovery.

2. That in other cases in which the post-operative condition is one of progressively increasing shock, due to the initial loss of blood and to the severity of the operative measures required, blood transfusion is a permanent resuscitative measure of extreme value.

It has been the unhappy lot of every surgeon in a casualty clearing station to have cases admitted under his care which required immediate operative attention, but were in such a collapsed and exsanguine condition that operation was out of the question. In certain of these cases a short operation (frequently amputation) is all the operative treatment immediately necessary, but the patient is unfit to withstand any operation owing to loss of blood and shock. Case 10 is typical of this class.

The Time for Blood Transfusion.

If the bleeding point can be controlled, as in the case of a shattered leg or thigh, the ideal time is as soon as the patient is seen. If operative interference is necessary before the bleeding can be controlled—for example, in intra-abdominal haemorrhage—blood transfusion may be carried out before the patient leaves the operating table. Usually, however, one is tempted to employ the ordinary resuscitative measures before resorting to blood transfusion, but it is unwise to wait too long.

Clinical observation appears to show that some degenerative changes take place in the organism when the exsanguinated condition persists for more than a few hours. If the patient is allowed to reach this stage he does not receive the same amount of benefit from the transfusion as when given earlier. For this reason it is advisable to give the blood as soon as possible after admission if circumstances permit.

Other great factors besides loss of blood in the production of shock are loss of body heat and physical exhaustion. After blood transfusion these other factors may be combated by providing warmth and rest for a few hours before operation. Acidosis incident to the shocked condition may be treated by the administration of sodium

bicarbonate. It is obvious that in severely wounded and exsanguinated patients there is a greater liability to the development of severe infection during their subsequent progress than if the anaemia were decreased by the addition of fresh blood.

The benefit of blood transfusion has its limitations, and it should not be used indiscriminately. It is, for example, of more limited value where gas gangrene has already developed, and should not be done unless the infected area can be either brought under control by excision or free drainage, or eliminated by amputation.

Amount of Blood to be Transfused.

This depends largely upon the giving capacity of the donor and the receiving capacity of the patient. A small patient will require proportionately less blood than a large heavily-built patient to produce the same effect on pulse and blood pressure. In severe primary haemorrhage 700 to 1,000 c.cm. may be regarded as an average amount, and will usually tide the patient over his crisis. Smaller amounts have been given with some success, but the most immediate and lasting improvement has been obtained with the large amounts. Cardiac dilatation in these exsanguinated recipients has not been observed even with the larger amounts. In transfusing 1,000 or 1,200 c.cm. the intervals between the injections of the blood-filled syringes should be longer towards the later part than at the beginning of the procedure, and the minimum amount of saline should be introduced into the recipient's vein between the injections of the blood-filled syringes.

The effects of loss of blood will show themselves at different times in the donor according to his size and robustness, the amount of blood, the rate at which it is removed, and the particular method employed. An impressionable donor will exhibit symptoms earlier than one of phlegmatic temperament. In none of the donors has anything more than temporary disturbance been observed. This coincides with the observations made by Colonel Fullerton,³ who had the opportunity of keeping donors under observation for some considerable time after they had given blood to patients.

The advisability of transfusing blood in the following cases was determined by the general condition of the patient, the pulse, and evidence of severe haemorrhage, the prospect of recovery after transfusion and operation, and in the later cases the blood pressure. A wounded man who has lost much blood and has a blood pressure below 90 mm. Hg is not a good subject for operation; with a blood pressure below 70 mm. Hg he is in a precarious condition. Loss of blood intensifies to a very great degree the amount of shock produced by traumatism, and in the majority of such cases the immediate issue depends upon control or elimination of the effects of haemorrhage.

Immediate Results.

In the cases of severe primary haemorrhage accompanied by shock, blood transfusion frequently produces an immediate and almost incredible improvement. The change from a pallid, sometimes semi-conscious patient with a rapid flickering pulse to a comparatively healthy-looking, conscious and comfortable patient with a slower and fuller pulse is dramatic evidence of the value of the transfused blood. The blood-pressure readings before and after show the remarkable change produced by the new blood. In those cases in which readings were taken during the subsequent forty-eight hours it was shown that this rise in blood pressure was well maintained. This is in marked contrast to the transient effect on the blood pressure of normal saline injections. The chart illustrates the gradual fall in pulse rate and rise in blood pressure during the blood transfusion. The immediate result of the transfusion is that it places the patient more on a footing with a man similarly wounded who has not lost more than a moderate amount of blood.

REPORTS OF CASES.

CASE 1.—G.S.W. Femur and Femoral Vessels: Amputation: Death.

Rfn. T. M. Admitted November 23rd, 1916, in extreme collapse. Compound fracture of left femur; femoral vessels severed. Intravenous saline was followed by temporary improvement for some hours, but condition was still inoperable. Blood transfusion (800 c.cm. by Unger two-way stopcock) followed by immediate improvement. Amputation of blood and fracture. Death in thirty-six hours from gas gangrene. Blood transfusion too far gone.

CASE 2.—G.S.W. Knee: Amputation: Recovery.

Pte. J. S. S. Admitted December 10th, 1916. Shattering fracture of leg involving knee-joint; profuse bleeding. He had received intravenous saline at the field ambulance. He was in a condition of collapse; pulse 134 and barely perceptible. Blood transfusion (500 c.cm. by citrate method) was followed by moderate but definite improvement. Two hours later amputation above knee. Next morning the pulse was 82, and the general condition immensely improved. Further progress uneventful. Evacuated to base in two weeks. A note from England four months later stated that reamputation had been done; stump healed rapidly; patient's health good.

CASE 3.—G.S.W. both Knees and Feet: Haemoglobinuria: Death.

Driver F. H. Admitted December 29th, 1916, in poor condition. Left foot blown away; severe compound fracture of right foot, and penetrating wounds of both knee-joints. Anti-shock measures were carried out, and when some improvement had taken place the wounds were dealt with. Post-operative condition bad. One litre of gelatin solution (Hogan) intravenously was followed by some improvement. On the following morning the condition was very poor; blood transfusion (750 c.cm. citrate method) was followed by marked reaction, but some improvement which was only temporary. He died in twenty hours. Haemoglobinuria present. There is no doubt that death was hastened by the occurrence of haemolysis.

CASE 4.—G.S.W. Shoulder: Evacuated to Base: Death Two Months Later.

Sapper B. O. J. Admitted January 6th, 1917, under the care of Captain S. J. Streight, C.A.M.C.; had bled profusely from a ragged perforating wound of the left shoulder. Compound fracture of scapula and head of humerus. Anti-shock measures were instituted, and twelve hours later operation was done; the shattered head of humerus was removed and torn circumflex vessels tied. His post-operative condition became progressively worse. Six hours after operation blood transfusion (760 c.cm. by citrate method) was followed by immediate improvement. Before transfusion the blood pressure was: systolic 75, diastolic 40; next morning: systolic 100, and diastolic 75. Improvement progressive. Evacuated to base four days later. Two months later he died at a base hospital from empyema following pneumonia. The progress of the wound had been slow but good.

CASE 5.—G.S.W. both Lower Limbs: Death from Shock.

Pte. R. F. Admitted February 3rd, 1917, in collapse; severe multiple wounds of both lower limbs (left leg almost severed) and left forearm and hand. Anti-shock measures were instituted, and ten hours later, when some improvement had occurred, operation was done. Intravenous saline at operation. Post-operative condition very poor. Blood transfusion (660 c.cm. by citrate method), five hours later, was followed by slight improvement which was not maintained. Died seven hours later from shock.

CASE 6.—G.S.W. Popliteal Artery: Amputation: Gas Gangrene: Death from Pulmonary Embolus.

Pte. T. D. Admitted in night of February 7th, 1917, in very poor condition. A shell fragment had severed the left popliteal artery, and his condition had been so bad that he had been unfit for transport from the field ambulance for several hours. Anti-shock measures were instituted, and some hours later blood transfusion (700 c.cm.) was done. Three hours later amputation was performed above the seat of injury. The patient withstood the operation well, but gas gangrene was present in the stump the next day; the infection was controlled by free incision. Five days after amputation he died very suddenly with signs of pulmonary embolus. Necropsy disclosed a long clot extending from the tied end of the femoral vein to its junction with the internal iliac vein.

CASE 7.—Penetrating Wound of Abdomen: Gas Infection: Death.

Pte. A. T. H. Admitted February 27th, 1917, with penetrating bullet wound of the abdomen. Sixteen hours after laparotomy the pulse became much weaker and more rapid. Blood transfusion (1,000 c.cm.) was followed by remarkable and immediate improvement, the pulse dropping from 140 to 108 after transfusion. The patient died thirty hours later from gas bacillus infection in a large retroperitoneal haematoma.

CASE 8.—G.S.W. Forearm: Circular Amputation: Secondary Amputation: Evacuated to Base.

Pte. T. Admitted April 21st, 1917 (under the care of Captain William Beggs, C.A.M.C.), in severe collapse. Bleeding from a shattered forearm had been profuse. Anti-shock measures were taken and five hours later circular amputation was performed. The post-operative condition became progressively worse for five hours when blood transfusion (1,160 c.cm.) was done and was followed by immediate improvement. Before transfusion: radial pulse 120 and barely perceptible, lips and face colourless; after transfusion: pulse 85 and of good tension; the face showed much improved colour. Four days later secondary amputation, flaps closed. Evacuated to base on the fourth day in excellent condition.

CASE 9.—Multiple G.S.W.: Eventually Evacuated to England in Satisfactory Condition.

Lieut. Cpl. F. was admitted under the care of Captain Beggs, C.A.M.C., with severe multiple wounds of arms and legs.

General condition very poor. Anti-shock measures for some hours; the left leg was then amputated and other wounds dealt with. The following day the general condition was poor; blood transfusion (500 c.cm.) was followed by immediate improvement. Further progress steady though slow. Evacuated to base on fourth day. Note received from base to the effect that the patient had been evacuated to England in satisfactory condition after severe illness.

CASE 10.—Multiple G.S.W.: Popliteal Vessels Torn: Evacuated to Base.

Lieut. V. Admitted May 17th, 1917; wounded seven hours previously. Left leg and knee shattered, popliteal vessels torn, penetrating wounds of left thigh, buttock, and face. Radial pulse 120 but almost imperceptible; face blanched. Anti-shock measures were applied, but one hour later the radial pulse was imperceptible, and the blood pressure below 40 mm. Hg. Death seemed imminent. Blood transfusion (1,100 c.cm.) was followed by immediate improvement. After transfusion the pulse was 130; blood pressure: systolic 120, diastolic 90. Half an hour later amputation was performed above the knee and the other wounds dealt with. Apart from transient sepsis on the face of the stump, due to the amputation having been made at the level of other wounds, progress was uneventful. Evacuated to base eight days later in very good condition.

CASE 11.—G.S.W. Elbow and Forearm: Evacuated to Base.

Sapper W. C. Admitted May 18th, 1917, in severe collapse; wounded seven hours previously. He had bled profusely from shattered left elbow and forearm. Blood transfusion (1,200 c.cm.) performed immediately, was followed by marked improvement. Before transfusion: pulse 154; blood pressure: systolic 62, diastolic 0. After transfusion: pulse 130; blood pressure: systolic 110, diastolic 80. Seven hours later amputation above elbow. Two hours after operation, pulse 114; blood pressure: systolic 120, diastolic 80. Further progress uneventful. Sent to base in six days in good condition.

CASE 12.—Lower Leg Blown away: Slow Recovery.

Pte. J. J. Admitted May 18th, 1917; the lower part of the left leg had been blown away six hours previously. He was collapsed and blanched. Blood transfusion (900 c.cm.) was followed by immediate improvement. Before transfusion: pulse 146; blood pressure: systolic 74, diastolic 20(?). After transfusion: pulse 92. Half an hour later amputation below the knee. Seven hours after operation: pulse 118; blood pressure: systolic 128, diastolic 70. Further progress good. Evacuated to base in six days. Two weeks later a note from England stated: "Flaps fairly clean; slow progress."

CASE 13.—Comminuted Fracture Femur and Thigh: Amputation: Death.

Pte. W. Admitted May 29th, 1917, five hours after having sustained a severe comminuted fracture of the femur extending into the knee-joint. He was collapsed. Blood transfusion (1,000 c.cm.) was followed by immediate improvement in the general condition and appearance. Before transfusion: pulse 120; blood pressure 96. After transfusion: pulse 100; blood pressure 110. Amputation above knee. The patient withstood the operation well, but died three days later of acute capillary bronchitis.

CASE 14.—G.S.W. Leg: Amputation: Evacuated to Base.

Pte. W. C. N. Admitted June 1st, 1917, with shattered right leg; he was blanched and had bled profusely. Blood transfusion (1,060 c.cm.) was followed by immediate improvement. Before transfusion: pulse 112; blood pressure: systolic 90, diastolic 32. After transfusion: pulse 76; blood pressure: systolic 134, diastolic 100. Half an hour later amputation above knee. The following day the patient was in excellent condition and was evacuated to the base.

CASE 15.—G.S.W.: Amputation Thigh and Arm: Evacuated to Base.

Driver L. H. B. Admitted May 29th, 1917 (under the care of Captain S. J. Streight, C.A.M.C.), with severe compound fracture of right tibia and fibula into the knee-joint, shattered right elbow and forearm, and penetrating wounds of the right thigh. Anti-shock measures were instituted. Amputations above the right knee and elbow were performed, and the other wounds dealt with. Post-operative condition became progressively worse. Five hours after operation blood transfusion (900 c.cm.) was done. Before transfusion: pulse 136; blood pressure: systolic 86, diastolic 54. After transfusion: pulse 120; blood pressure: systolic 140, diastolic 74. Progress uneventful; evacuated to base on fourth day in good condition.

CASE 16.—Multiple G.S.W.: Amputation: Recovery.

Second Lieut. M. Admitted in severe shock and collapse; wounded seven hours previously. Left forearm shattered; penetrating wounds of right knee-joint, calf, and foot; right ankle disorganized by large perforating wound; large dirty perforating wound of left loin opening into extraperitoneal space. Condition quite inoperable. Anti-shock measures were of little avail. Immediate improvement followed blood transfusion (1,100 c.cm.). Before transfusion: pulse 132; blood pressure: systolic 90, diastolic 33. After transfusion: pulse 140; blood pressure: systolic 120, diastolic 74. Four hours later, under gas and oxygen, amputation of left arm (gas gangrene); loin wound thoroughly excised, other wounds dressed. On the

following day amputation above the right knee was performed. Further progress was uneventful, and he was sent to the base four days later. A note was received from the base stating that ten days later the flaps were sutured, and three weeks after being wounded he was evacuated to England, "the wounds healing nicely and condition much improved."

CASE 17.—Perforating Wound Stomach: Laparotomy: Haemoglobinuria: Death.

Lieut. H. Admitted in shocked condition; penetrating wound of abdomen; excessive amount of blood vomited. Laparotomy disclosed perforated stomach and active bleeding from severed gastro-epiploic artery; abdominal cavity full of bright blood. After operation pulse almost gone; patient very blanched. Blood transfusion (1,000 c.cm.) done. Before transfusion: pulse 130; blood pressure: systolic 66, diastolic 0. After transfusion: pulse 92; blood pressure: systolic 170, diastolic 72. High systolic pressure due to injection of pituitrin given at the end of operation. During transfusion there was slight respiratory distress after 140 c.cm. of blood had been injected, but it was difficult to judge on account of the effects of the anaesthetic. Two hours later the pulse became weaker, and the patient died in a few hours. At necropsy some haemoglobinuria was evident. There is no doubt that a haemolytic reaction due to the transfused blood hastened the death of this patient.

CASE 18.—G.S.W. involving Tibial Arteries: Gas Gangrene: Transfusion Delayed: Double Amputation: Death.

Lieut. Cpl. A., admitted June 7th, 1917; wounded the previous day. Perforating wounds of both legs, severing both posterior tibial arteries. Practically moribund condition; inoperable. Anti-shock measures were carried out in the resuscitation ward with little effect. Some hours later gas gangrene was evident in both legs, and the patient was unconscious and pulseless. At this time it was thought that blood transfusion followed by operation would give him his only chance. The response to blood transfusion (1,000 c.cm.) was extraordinary. Breathing, which at first was shallow and sighing, became quiet and regular; the pulse grew perceptibly, and though rapid was of good character. Colour returned to his face, and half-way through the procedure he became conscious. At the end of the transfusion he quite conscious and talked rationally. Half an hour later double amputation above the knees was done under gas and oxygen, but the patient died at the end of the operation. Had circumstances allowed of an earlier transfusion I feel sure that a successful result might have been expected.

CASE 19.—G.S.W. Leg: Immediate Amputation: Transfusion: Evacuated to Base.

Capt. A. C. T. Admitted June 13th, 1917; wounded five hours previously. There had been profuse haemorrhage from shattered leg. Pulse only 108, but of low tension. Immediate amputation for persistent bleeding from popliteal space. Post-operative condition progressively worse. Two hours later the patient was very collapsed and could be roused only with difficulty. Blood transfusion (1,100 c.cm.). Before transfusion: pulse 108; blood pressure: systolic 66, diastolic below 20. After transfusion: pulse 84; blood pressure: systolic 120, diastolic 66. Half-way through transfusion the patient was quite conscious; at the end of the procedure he asked for a cigarette and smoked it with enjoyment. Further progress was uneventful. He was sent to the base in five days. Note from base stated "Condition suitable for immediate transference to England."

CASE 20.—Left Thigh Blown Away: Amputation: Death.

Gunner W. Admitted June 18th, 1917, six hours after being wounded. Left thigh almost completely blown away below the middle; severe shock and collapse. Blood transfusion (700 c.cm.) was followed by immediate improvement. Before transfusion: pulse 130; blood pressure: systolic 80, diastolic 50. After transfusion: pulse 92; blood pressure: systolic 124, diastolic 78. Following this amputation was done, but the patient stood the operation badly and died ten hours later from shock.

CASE 21.—G.S.W. Hip, Leg, and Arm: Amputation below Knee: Evacuated to Base in Good Condition.

Capt. G. S. T. Admitted June 17th, 1917 (under the care of Captain S. J. Streight, C.A.M.C.), in collapsed condition. Right leg shattered; compound fracture of right great trochanter; penetrating wound of arm. Blood transfusion (1,200 c.cm.). Before transfusion: pulse 134; blood pressure: systolic 70, diastolic 40. After transfusion: pulse 94; blood pressure: systolic 128, diastolic 80. Four hours later amputation below knee and other wounds dealt with. Sent to base in four days. He was evacuated to England in a satisfactory condition.

CASE 22.—Buried: Abdominal Injuries and Fractured Femur: Laparotomy: Evacuated to Base in Good Condition.

Pte. F. McL. Admitted July 4th, 1917. Had been buried by a shell seven hours previously; was in a condition of shock and collapse from intra-abdominal injury and fracture of femur. Anti-shock measures for some hours produced slight improvement. Laparotomy; abdomen full of bright blood and urine; two-inch tear in bladder; lower part of spleen completely torn away; profuse spouting of blood from the remainder at the first touch. Splenectomy and bladder suture. Thomas splint to thigh. During operation pituitrin (1 c.cm.) was given and saline (30 oz.) introduced into vein. At the end of the operation the patient was very blanched and the pulse poor. Blood

transfusion (1,000 c.cm.). Before transfusion: pulse 180; blood pressure: systolic 80, diastolic 40. After transfusion: pulse 140; blood pressure: systolic 185, diastolic 80. High systolic pressure evidently due to pituitrin, as seven hours later it had dropped to 136, diastolic being maintained at 80. Further progress uneventful. Evacuated to base in two weeks. Four weeks after operation a note was received from the base stating that the patient was in excellent condition and recovery seemed assured.

CASE 23.—G.S.W. both Legs. Amputation: Evacuated to Base in Good Condition.

Pte. G. G. H. Admitted July 11th, 1917, in severe collapse.

Compound fracture

of left leg and rupture of both tibial arteries; large wound of right leg with tear of posterior tibial artery. Had bled profusely.

Anti-shock measures produced little improvement. Blood transfusion (1,000 c.cm.) was followed by immediate improvement. Before transfusion: pulse 144; blood pressure: systolic 62, diastolic 40. After transfusion: pulse 96; blood pressure: systolic 126, diastolic 60. Several hours later amputation of left leg below knee, and other wounds dealt with. Further progress uneventful. Sent to base in four days in good condition. He was evacuated to England in good condition three weeks after being wounded.

Chart of Case 23, showing fall in pulse rate and rise in blood pressure during the course of the transfusion of 1,000 c.cm. of blood.

CASE 24.—G.S.W. Popliteal Artery and Knee. Amputation: Evacuated to Base in Good Condition.

Pte. F. S. Admitted in collapsed condition on July 12th, 1917, seven hours after being wounded. Shell wounds of left buttock, leg, and foot; right popliteal artery severed and fracture of femur, involving right knee-joint. Anti-shock measures were carried out, with only temporary improvement. Four hours later blood transfusion (1,000 c.cm.). Before transfusion: pulse 156, blood pressure 80. After transfusion: pulse 120, blood pressure 136. Three hours later amputation above right knee, and other wounds dealt with, under gas-oxygen anaesthesia. Five hours after operation: pulse 128, blood pressure 120. Further progress uneventful. Evacuated to base on fifth day in good condition, with clean wounds and stump.

CASE 25.—G.S.W. Chest, Femoral Vein, Knee-joint: Evacuated to Base in Good Condition.

Dr. C. J. B. Admitted in very grave condition under the care of Major G. E. Gask, D.S.O., R.A.M.C.(T.). Penetrating wound of chest; tear of left femoral vein; penetrating wound of right knee-joint. After operation the patient was blanched and collapsed; the pulse was 180 and barely perceptible; blood pressure 60 mm. Hg. Blood transfusion was started, but before 60 c.cm. had been injected death was imminent. The patient's lips were bloodless, pulse imperceptible, breathing slow and jerky; 80 c.cm. of very hot saline and 1 c.cm. pituitrin were now given intravenously and the transfusion continued. When 400 c.cm. of blood had been injected the breathing had improved greatly. At the end of the transfusion (1,200 c.cm.) the face was flushed, pulse strong, and the patient was attempting to clear his throat. After transfusion: pulse 108, blood pressure 144. Further progress uneventful. Evacuated to base seven days later. Two weeks later he had been evacuated to England in good condition.

CASE 26.—G.S.W. Chest: Haemothorax and Laceration of Lung: Death.

Gunner E. G., wounded early that morning, was admitted in very collapsed condition under the care of Major G. E. Gask, D.S.O., R.A.M.C.(T.), on July 17th, 1917. Severe penetrating wound of chest; extensive damage to lung. Blood transfusion (700 c.cm.). There was slight response lasting a very short time. Death occurred some five hours later. Necropsy showed gas bacillus infection in haemothorax, and severe laceration of lung.

CASE 27.—Penetrating Wound of Abdomen: Laparotomy: Death.

Gunner C. H. W. Admitted July 25th, 1917, in collapsed and pulseless condition. Large penetrating wound of lower abdomen. Anti-shock measures were instituted and pulse returned—96. Laparotomy eight hours after wound was received; resection of 18 in. of small gut; suture of bladder and two tears in rectum. The abdomen was filled with blood and clot; after operation the patient was pulseless. Blood transfusion (1,100 c.cm.) was done, but the patient was too far gone to benefit by it, and died in less than three hours.

CASE 28.—Multiple G.S.W. both Lower Limbs: Amputation of Thigh and Wrist: Evacuated to Base.

Lieut.-Col. R.A.M.C., aged 50, was admitted in collapsed condition seven hours after being wounded; pulse almost imperceptible; face greyish-blue, condition inoperable. Severe compound fracture below right knee, penetrating wound right knee-joint, right hand blown off, left brachial artery severed, large perforating wounds of left thigh. Blood transfusion (1,200 c.cm.) was followed by immediate improvement. Four hours later operation was carried out under light chloroform anaesthesia, three teams being concentrated on the case; amputation above right knee, ligation of left brachial artery, excision of wounds of left thigh, amputation through right carpus. Further progress slow but good. Evacuated to base four days later; temperature 98°, pulse 88. Two weeks later wounds reported to be improving.

CASE 29.—G.S.W. Chest: Recovery.

2nd Lieut. A. J. D. Admitted July 29th, 1917, under the care of Major G. E. Gask, D.S.O., R.A.M.C., in a collapsed condition; severe penetrating wound of chest, from which there had been a large amount of bleeding. Condition inoperable. Blood transfusion (740 c.cm.) carried out. After 100 c.cm. had been injected operation was begun. Thoracotomy, removal of shell fragments, irrigation of pleural cavity, closure of chest wall. Further progress good. Evacuated to base nine days later in good condition.

CASE 30.—G.S.W. both Legs: Double Amputation: Evacuated to Base in Good Condition.

Pte. H. G. Admitted on July 29th, 1917, six hours after being wounded, in very collapsed condition. Right leg shattered and vessels torn; extensive wound of left calf, with shell fragment embedded in muscles; pulse rapid and flickering, lips bluish-white. Blood transfusion (1,200 c.cm.). Two hours later amputation above right knee (for gas gangrene), left calf widely opened up. Next morning the patient was very much improved, but by evening gas gangrene of left leg was present, and amputation above the left knee was done under gas-oxygen anaesthesia. The following day there was persistent vomiting (acidosis), which was relieved by an intravenous injection of 20 oz. of 5 per cent. sodium bicarbonate solution. Further progress uneventful. Evacuated to base five days after admission in very good condition; both thigh stumps clean.

CASE 31.—Amputation of Forearm and Thigh: Gas Gangrene: Death.

Gunner W. P. Admitted August 4th, 1917, in collapsed condition. Right forearm shattered; compound fracture of right femur with severing of popliteal vessels. Anti-shock measures carried out, but only slight improvement resulted. Blood transfusion (1,000 c.cm.) was followed by immediate and marked improvement. Amputation through forearm and thigh now done. The patient withstood operation well, but died in thirty-six hours from extensive gas gangrene of right thigh.

CASE 32.—G.S.W. Thigh and Leg: Evacuated in Good Condition.

Pte. D. O'L. Admitted August 5th, 1917, in very collapsed condition; had sustained, forty-eight hours previously, a large wound in left thigh, and while lying out in a shell-hole twenty-four hours later had received a second and extensive wound in the left calf. There had been severe haemorrhage from the latter. Anti-shock measures were instituted, but with only slight improvement. Immediate improvement followed blood transfusion (1,100 c.cm.). Before transfusion: pulse 132, blood pressure 90. After transfusion: pulse 95, blood pressure 142. One hour later operation was done. Further progress good. Evacuated to the base in two days in very good condition. It is interesting to note that at the end of the transfusion there was a marked urticarial eruption (serum rash?) over the trunk and extremities. It had subsided in less than twenty-four hours.

CASE 33.—G.S.W. Knee: Amputation: Evacuated to Base in Good Condition.

Lieut. J. K. P. Admitted August 5th, 1917 (under the care of Captain W. Beggs, C.A.M.C.), in very poor condition, twenty-four hours after sustaining a severe compound fracture of the left leg into knee-joint with damage to vessels. After anti-shock measures, drainage established and bleeding controlled. The next day the pulse was very rapid, face still blanched, leg becoming swollen. Blood transfusion (530 c.cm.). Before transfusion: pulse 178. After transfusion: pulse 132. Amputation above knee. Further progress uneventful. Evacuated to base on August 9th in good condition; pulse 90.

CASE 34.—G.S.W. Thigh: Amputation: Death.

Pte. J. W. Admitted August 10th, 1917. Wounded twelve hours before. Extensive comminution of right femur; anterior muscles blown away, but hamstrings intact; femoral vessels torn. Condition of profound collapse. Anti-shock measures instituted on admission with very little effect. Blood transfusion (1,000 c.cm.) two hours later. Before transfusion: pulse 152, blood pressure 72. After transfusion: pulse 130, blood pressure 146. Patient suffering from toxæmia due to gangrenous condition of muscles. High amputation done one hour after transfusion, but intramuscular planes found to be extensively infected up to groin. Death twenty hours later.

CASE 35.—G.S.W. Knee: Amputation: Evacuated in Good Condition.

Lieut.-Cpl. L. H. Wounded the previous evening; admitted morning of August 11th, 1917. Right leg shattered, involving knee-joint; part of right tarsus blown away. Anti-shock measures for several hours, with no effect. Blood transfusion (700 c.cm.). Before transfusion: pulse 152; blood pressure: systolic 60, diastolic 0. After transfusion: pulse 114; blood pressure: systolic 120, diastolic 60. Amputation above right knee. Further progress uneventful. Evacuated to base in good condition on fourth day.

CASE 36.—G.S.W. Popliteal Artery and Vein: Amputation: Evacuated in Good Condition.

Pte. A. H. C. Admitted August 11th, 1917, collapsed and almost pulseless; had bled profusely from gaping wound in right popliteal space. Anti-shock measures had very little effect. Blood transfusion (1,000 c.cm.) was followed by immediate improvement. Before transfusion: pulse 124; blood pressure: systolic 74, diastolic 15. After transfusion: pulse 110; blood pressure: systolic 142, diastolic 68. Amputation above wound two hours later under gas-oxygen anaesthesia. Examination of amputated leg showed complete division of popliteal vein and large tear in popliteal artery. Further progress uneventful. Evacuated to base in good condition on fourth day.

In reviewing these cases of primary haemorrhage I feel that better results might have been obtained in Cases 1, 7, and 18. In Case 1 the fatal issue was due to the early development of gas gangrene, which might have been eliminated by amputation had the transfusion been done earlier. In Case 9 an earlier transfusion would have permitted earlier amputation, which would have rendered less likely the development of gas gangrene. Though the infection in this case was controlled it was responsible, apparently, for thrombosis in the femoral vein with subsequent death from pulmonary embolism. Case 18 was seen during the rush of the Messines battle. Measures to counteract shock were carried out in the resuscitation ward, but were unsuccessful. Although the blood transfusion produced a startling improvement his toxæmia was too intense to allow him to withstand the anaesthetic and the shock of the operation.

CONCLUSIONS.

1. Many cases admitted in an inoperable condition from severe haemorrhage have been rendered operable by blood transfusion.
2. The largest factor in the causation of the condition of shock as seen in patients admitted to a casualty clearing station appears to be the loss of blood, except in cases of visceral injury.
3. In two cases haemolysis hastened the death of the patient. In one of these the citrate method was used. The possibility of haemolysis certainly is present, but the danger of its occurrence is slight in comparison with the danger of operating on a shocked and exsanguined patient.
4. The results in this series of cases of severe primary haemorrhage may be classified as:

Life saving	22
Immediately beneficial, but died from infection or operation	9
No benefit	3
Harmful	2
Total	36

5. Although the mortality in this series of cases is comparatively high, it must be remembered that all the patients were in a desperate condition, and with, perhaps, one possible exception, could not have been expected to survive if the procedure had been withheld.

NOTE BY COLONEL C. GORDON WATSON.

During the past year I have had the opportunity of observing the technique and the results of blood transfusion by Major Bruce Robertson and other workers.

Without doubt transfusion of blood after primary haemorrhage is a life-saving device of the greatest value and enables urgent operations to be successfully performed under conditions otherwise hopeless. In the past blood transfusion has failed to come to the fore owing to technical difficulties. The stimulus of war and the

urgent need for blood transfusion has resulted in greater familiarity with the technique.

For many years past we have, in England at any rate, trusted to saline infusion to restore the balance after haemorrhage. So far as my experience goes, there is no comparison between the results of blood transfusion and saline infusion. The effects of blood transfusion are instantaneous and usually lasting; the effects of saline too often transitory—a flash in the pan—followed by greater collapse than before.

In civil practice, speaking generally, the occasions for transfusion are few; in military practice, in the forward line, the exsanguined wounded man is regularly met with in the reception room.

The problems of shock and collapse are receiving every day greater attention. In every casualty clearing station there is a resuscitation ward with beds heated by hot air or electric light and with arrangements for giving hypertonic intravenous infusions, and so on. Here we endeavour to estimate the shock of battle, the shock that follows trauma or loss of blood, or the shock of toxæmia, to assess the proportionate damages to each, and to apply the appropriate remedy.

The methods of blood transfusion employed in the casualty clearing stations vary with the individual surgeon. Major Robertson has acquired great dexterity with the syringe method, and his results are correspondingly good.

Practice in team work is essential to success, and the two surgeons and the syringe orderly must drill together. Record syringes can be relied on for the purpose; others cannot.

The scope of blood transfusion is not limited to primary haemorrhage. It is of undoubted value for secondary haemorrhage, and we have used it successfully also as a sequel to venesection in two severe cases of carbon monoxide poisoning.

In the selection of a donor for blood transfusion, certain precautions should be taken when the circumstances of the case permit. At the front, particularly during the periods of heavy fighting, time does not permit of tests to eliminate syphilitic taint, nor, indeed, to ascertain if the blood of the donor is incompatible with that of the patient. Such risk as there is must be run if the urgent need of the patient is to be met promptly.

I have more than once seen alarming symptoms arise during transfusion. In one case the pupils dilated, the eyes were turned up, the pulse-rate increased, and the patient became pallid and unconscious, and died the same day. At the necropsy the blood was completely haemolysed. The condition of the wounds, however, showed that the chances of recovery were remote. In other instances I have noted transitory respiratory distress, sweating and precordial pain, followed subsequently by a varying amount of haemoglobinuria. The occurrence of rigors with a transitory rise of temperature are by no means uncommon after transfusion and are not an indication of incompatibility of bloods.

Too rapid transfusion may be followed by acute dilatation of the heart when the myocardium is exhausted and weakened by haemorrhage and shock. As Crile has pointed out, the work of the heart increases in geometric ratio to the volume of blood, and it is easy to realize the risk involved in suddenly producing a rapid increase in the volume of blood when the heart is already tired out. I have seen this exemplified in one case.

I feel confident that blood transfusion has become a permanent method, and that under the stimulus of war and the mass of material that war provides, our methods will steadily improve. The excellent results which Major Robertson has secured will, I hope, stimulate other surgeons to increased activity in the practice of this life-saving device.

WHEN delegates of the profession of the Republic of Uruguay recently visited France they were received at the Paris Faculty of Medicine on October 14th by Professor Gaucher, president of the General Medical Association of France, who recalled the fact that on the initiative of Professor Enrique Pouey of Montevideo the doctors of Uruguay had sent to the French fund for the medical victims of the war a sum of £1,360, contributed by 210 doctors in a country of not more than one million inhabitants. Professor Pouey himself had sent the whole of his salary.

DIRECT TRANSFUSION OF BLOOD.

BY

LIEUT.-COLONEL ALFRED J. HULL, F.R.C.S.,

ROYAL ARMY MEDICAL CORPS.

ALTHOUGH the advantages of direct transfusion are so apparent, this treatment does not appear to be in such frequent use as it merits.

Apart from its obvious indication in cases of severe haemorrhage, it would appear to be a valuable treatment for severe sepsis and shock. The provision of healthy blood to patients suffering from septicaemia must supply

FIG. 1.—The position of the arms. The donor's left hand grasps the patient's left arm well above the elbow, bringing the donor's radial artery almost into apposition with the patient's median basilic vein.

them with the bactericidal agents, bacteriolysins, antibodies, agglutinins, opsonins, leucocytes, and tryptic power which they are deficient in.

How far the alteration of the blood in cases of shock determines the result is at present uncertain, but the effect of healthy blood upon the tissues of such patients appears to be worthy of consideration.

Transfusion would appear to be a more scientific remedy than the empirical injection of antiseptics into the blood stream.

The difficulty of obtaining some one willing to submit to an operation entailing ligation of an artery is in my opinion the only bar to a much greater use of this treatment.

The operation is very simple and can be performed without the use of special apparatus. In fact, I consider the use of any apparatus most undesirable.

FIG. 2.—The preparation of the vessels. The radial artery has been cleaned for about an inch, divided, and drawn out of the wound. A traction suture has been tied on to the artery. The patient's vein has been exposed and lifted by two probes. By means of its needle the traction suture has been passed through the incision in the vein and out of the vein wall about an inch higher up the vessel.

To be efficient and certain in its results the operation should be performed by the direct transfusion of blood from artery to vein. It is only in this way that clotting, the one danger of transfusion, can be avoided with certainty. The only disadvantage of this method is that the amount of blood transfused cannot be measured, but this is outweighed by the safety and simplicity of the method, and moreover the amount of blood which flows before the donor becomes faint is fairly constant.

Position of the Patient and Donor.

The left hand of donor grasps the arm of the patient just above the elbow, bringing the donor's radial artery in close proximity to the patient's median basilic vein.

THE OPERATION.

An incision about 2 in. in length is made in the patient's arm over the median basilic vein.

The Preparation of the Artery.—A similar incision is made over the radial artery of the donor. The artery is

FIG. 3.—The insertion of the artery. The donor's and patient's arms have been rotated a short distance, bringing the wounds almost into apposition. Traction has been made upon the radial artery by means of the traction suture and the artery has been drawn into the vein. A ligature has been placed in the vein wall ready for tightening.

cleaned for about an inch, the lower end of the artery in the wound is clipped, digital pressure is made over the brachial artery, and the radial is cut above the clip. The end of the radial artery is pulled out of the wound, and a traction suture is tied through the wall of the artery.

The Preparation of the Vein.—Two probes about an inch apart are passed under the vein for haemostatic purposes. A small cut is made into the vein (2 mm. in length); through this the needle bearing the traction ligature from the radial artery is passed. The needle emerges from the vein an inch above the incision. A second suture is now passed through the wound in the vein; this suture is used to close the vein when the artery has been inserted. By drawing upon the traction suture the artery is drawn into the vein, the vein suture is tied, and the probes and digital pressure removed.

The blood is allowed to flow until the donor feels faint. The artery is then clipped, pulled out, and ligatured. The whole procedure is carried out under local anaesthesia.

It may be objected that making use of the radial artery as a cannula involves a serious and avoidable mutilation of the donor. This is not the case; ligature of the radial artery must be performed in any case, and the excision of an inch or so of the vessel makes no difference. The elasticity of the artery renders its use as a cannula easy, and a considerable length of vessel becomes available through a comparative small wound.

A SIMPLE AND RAPID METHOD FOR THE SELECTION OF SUITABLE DONORS FOR TRANSFUSION BY THE DETERMINA- TION OF BLOOD GROUPS.

BY

ROGER I. LEE, MAJOR M.O.R.C., U.S.A.,
U.S. ARMY BASE HOSPITAL No. 5, B.E.F.

TRANSFUSION has now become a very valuable and widely accepted form of treatment in a large group of selected cases. With improved methods, and with increased skill and experience in the technique, there will probably be a very great increase in the number of transfusions performed.

There still exists a good deal of confusion as to the selection of the suitable donors. It has been a common experience that transfusion, without preliminary tests, may be performed in a considerable series of cases without detriment to the patient. On the other hand, promiscuous transfusions inevitably lead to disastrous results, which may be fatal.

It has long been known that all individuals are divided into four blood groups. These groups are not established at

birth, but become so in the first year of life. Apparently, the blood group of an individual follows the Mendelian law. Using the arbitrary classification of four groups, it is found that approximately:

8 per cent. of individuals fall in Group I.
Nearly 40 per cent. in Group II.
10 per cent. in Group III.
42 per cent. in Group IV.

This does not mean, however, that it is necessary that the donor and recipient should be in the same group. There is abundant laboratory and clinical evidence to show that the only important consideration is that the serum of the patient or recipient does not agglutinate or haemolyze the red corpuscles of the donor. The reason for this is that in the ordinary transfusion one adds from the donor only about one-fifth to one-twelfth of the total blood volume of the patient. The donor's serum is therefore diluted, and prevented from acting in a detrimental fashion. Furthermore, as has also been shown, the patient's cells are amply protected in that dilution by his own serum. Consequently, any transfusion between groups is permissible and harmless, provided the patient's serum does not agglutinate and haemolyze the donor's red corpuscles, although the donor's serum in the test may agglutinate and haemolyze the patient's red corpuscles. This is illustrated by the table, from which it will be seen that if a patient is in

		Serum of Group			
		I.	II.	III.	IV.
Cells of Group I	...	—	+	+	+
" "	II	0	—	+	+
" "	III	0	+	—	+
" "	IV	0	0	0	—

+ = Agglutination and haemolysis.
0 = No agglutination and haemolysis.

Group I he can receive blood from any donor, because the serum of Group I will neither haemolyze nor agglutinate the red cells of any group. On the other hand, the cells of Group I are agglutinated and haemolyzed by all other serums except that of Group I (its own group). Fortunately this group is small. A Group I person is therefore known as the universal recipient. In contrast to Group I, we have Group IV, the largest group, whose cells are agglutinated and haemolyzed by no group, but whose serum will agglutinate and haemolyze the red corpuscles of all other groups. Group IV is known as the universal donor group, since the blood of Group IV can be transfused with safety into any patient. Furthermore, if the patient belongs to Group IV, he can only receive the blood of the same group.

One other factor which may prevent disaster is the variation in the strength of the agglutinating and haemolytic power of a given serum. It has been found that persons within the same group vary greatly in the potency of the agglutinating and haemolytic power of their serums. Thus a cross-transfusion may result in an immediate fatality in one instance, in complete destruction of the red blood corpuscles, haemoglobinuria, and marked jaundice, but without death, in another, and only mild symptoms in the third patient. I have seen an accidental cross-transfusion in a patient, with only mild symptoms, followed some weeks later by a second transfusion of the same amount from the same donor, with death. The explanation, of course, is the development of the agglutinins and haemolysins under the influence of the injection of the suitable protein.

In cases of dire necessity transfusion without tests is, of course, permissible, but it would seem to be almost unnecessary. The minimum procedure should consist of the establishment of the fact that the patient's serum does not agglutinate the donor's cells. This can readily be performed as follows:

A small amount of blood is collected from a patient (1 c.cm. from the ear or finger is sufficient), and allowed to clot. The serum is then obtained. One drop of this serum is placed upon a slide and mixed with a drop of a suspension of blood of the donor taken into 1.5 per cent. citrate solution. (A few drops of blood are taken into approximately ten times the amount of 1.5 citrate solution and shaken. It is very important that the blood be dropped directly in the citrate, and should not be partially coagulated.) The test will appear in a few moments,

and is best examined under the microscope, where, in the event of a positive test, marked agglutination will be evident. The test will also be evident macroscopically. In the event of a negative test it is a wise precaution to raise the cover-glass, and after making sure that the serum and cells are well mixed, to examine the preparation again. The only possible source of confusion is the appearance of rouleaux of the red corpuscles, indicating a too thick emulsion. If the test is negative, transfusion may be regarded as entirely safe.

Our own experience in civil practice, and particularly in base hospital work, has caused us to adopt another procedure. We have constantly on hand a supply of serums known to be Group II, Group III, and Group IV. As soon as persons who belong to Groups II and III have been ascertained—for example, among the medical officers or laboratory attendants—it is possible to determine the blood group of any given individual very readily, and these known persons, or test persons, can act as a supply of the known serums. From the table it can also be seen that, if it is known that any individual is in either Group II or III, all the other groups can be established. By using the serum of Groups II and III, one has only to collect the blood of the person to be tested in citrate solution, and the test can be performed immediately. If the serum of unknown blood is tested against the known cells, it is necessary to await the development of serum after clotting. In case a blood of a known group is not available, it is only necessary to test out, in the manner described above, a series of bloods against each other. By referring to the table the bloods will be found to resolve themselves into the several groups. The usual groups will be II and IV. As soon as a blood of Group III is secured, then a supply of serums is obtained from Groups II, III, and IV, and rapid tests can be made. If the serums are sterile, they can be kept indefinitely. The serum of Group IV is simply used as a control.

Routine Method.

With the serums of Groups II, III, and IV a number of donors are tested and their names and groups are posted in the operating room. In the event of adequate time the patients' blood is also grouped, in order to use up the donors of groups other than IV. However, in the case of an emergency no further tests are necessary. A donor from Group IV is taken and transfusion immediately performed. This procedure has been of great value in our work at a base hospital, since sudden, severe haemorrhages often happen at night, and without further delay a safe transfusion from a Group IV donor is performed, without testing the patient's blood.

In view of the above fact, and in view of the very simple requirements of the test to establish the safety of transfusion, it seems evident that whenever possible a preliminary blood test should be made before transfusion in order to avoid untoward results. It has been demonstrated again and again that without tests fatalities occur, and that frequently severe reactions occur, which destroy all the benefit of the transfusion. The test which has been recently advocated of giving a few cubic centimetres of blood and awaiting the appearance of the well recognized symptoms of agglutination and haemolysis in the patient, does not seem to be necessary, and furthermore, delays the transfusion and permits the changes in the blood to occur that eventually lead to coagulation, and which so alter the protein molecules of the blood that the blood itself may have very toxic qualities.

In a considerable experience, under the conditions set down above, no disastrous effects have been seen from transfusion, and no evidence has ever been found of haemolysis, as indicated by the appearance of jaundice, or the careful testing of the urine for haemoglobin, even when the permissible cross-transfusions were performed repeatedly on the same patient.

IN co-operation with the General Education Board the Rockefeller Foundation has turned its attention to the development of medical education in several centres in the United States. They have each contributed £200,000 to the University of Chicago for that purpose. The Rockefeller Foundation is also co-operating with Johns Hopkins University in the establishment of a school of hygiene and public health, towards which it has made an appropriation of £53,400. The school opened in October with Dr. William H. Welch as director. It offers instruction and facilities for research in hygiene, sanitation, and preventive medicine to doctors and medical students, biologists, chemists, and engineers.

VINCENT'S ANGINA AMONG THE TROOPS IN FRANCE.

By CAPTAIN R. J. C. BOUTY, R.A.M.C.

DURING the last two years there has been a gradual and marked increase in the number of cases of Vincent's angina among the troops in France, both British and French. In time of peace this disease forms about 2 or 3 per cent. of all cases of throat complaints among the French army (recent statistics). Recent statistics from a British military hospital in France show the proportion to be as high as 23 per cent.

The following notes are based on a number of cases which have come under my observation.

Symptoms.

The disease is characterized by the formation of ulcers on the buccal and pharyngeal mucous membrane, either superficial or deep, covered by a pseudo-membrane; the most common site is the tonsil. The organism is one normally present in the mouth of healthy individuals, but seems to favour irritated conditions of the mucous membrane. Vincent himself considers excessive smoking one of the chief predisposing factors, as also the presence of decaying organic matter, and any irritant fumes, such as those given off from exploding shells. It is a disease prevalent among students working in the dissecting-room, and in hospitals generally, and among nurses.

The onset is sudden, and may be preceded by a few days' malaise. The temperature is raised for the first day or two, and may be high, the membrane often not commencing to form for twenty-four to forty-eight hours after the commencement of the fever. The membrane is rapidly formed, is thick and abundant, and appears, as a rule, on one tonsil at first. After the first two days the temperature may fall to normal, and remain normal, or there may be an irregular slight pyrexia throughout. This more often occurs in the more severe type with complications, such as marked adenitis or albuminuria, etc. The membrane is yellowish-white and abundant, it is adherent, and leaves a raw bleeding surface on removal. Although the tonsil is generally the part affected, the ulcer may be found only on the anterior or posterior pillar of the fauces, or the uvula alone, or the soft palate alone. It may commence on the tonsil, and spread to the uvula, pharyngeal wall, or soft palate, causing considerable destruction of tissue. The breath has an unpleasant odour, worse than in the case of diphtheria.

As a rule, if thoroughly treated, the membrane disappears in a few days. In some cases, however, some days, or as much as a fortnight, after recovery, there is a further rise of temperature, and commencing ulceration of the other tonsil. A chronic or severe form is sometimes seen, persisting for some weeks, and in these cases complications arise, and may be serious. Some cases of death have occurred in French hospitals, in which the primary cause was Vincent's angina.

Etiology.

Microscopically, two varieties of organism are found, the *Bacillus fusiformis* and Vincent's spirochaete.

Two forms of Vincent's angina are met with—(1) the pseudo-membranous, resembling diphtheria in appearance, and (2) the ulcerative form.

In the first we find abundant bacilli mixed with cocci, and in the second, associated with the bacillus, a Gram-negative mobile flagellated spirillum. A coexisting streptococcal infection is not uncommon, and may give rise to serious complications.

The Ziehl-Nielsen method is all that is required, though the silver method demonstrates the spirochaete more clearly. Injected into animals the organisms are non-pathogenic. Injection of impure cultures causes abscesses in which the spirochaete is abundant.

Letulle states that in every case of ulceration in the mouth, whether syphilitic, tuberculous, or cancerous, large numbers of *B. fusiformis* and spigilla are to be found.

Complications.

The complications which may occur are:

Adenitis of the cervical glands in nearly every case, and often very painful.

Pyorrhoea alveolaris is often present.

Stomatitis and gingivitis.

Quinsy is a not uncommon complication.

Gastro-enteritis cases have occurred in which, *post mortem*, abundant bacilli and spirochaetes have been found in the intestines (Vincent).

Nephritis and albuminuria. The urine of these patients often contains a trace of albumin, and in some cases acute nephritis may occur. To quote one example:

A doctor working at a base hospital was three weeks in hospital with Vincent's angina, and on recovery was given three weeks' sick leave. Whilst in England it recurred on the same tonsil, the recurrence only lasting a few days. On return to duty he had a third attack on the opposite side, and was admitted to hospital, his urine containing a trace of albumin. Three days after admission he developed acute nephritis. Twelve days later the albumin and casts had entirely disappeared.

Other complications are ulceration of the pharynx, on some occasions causing perforation of the carotid artery (Vincent), bronchitis, laryngitis, with ulceration of the vocal cords, pleurisy, empyema, otitis media, cachexia, endocarditis.

A case of gangrene of the vulva and perineum caused by *B. fusiformis* and Vincent's spirochaete in large numbers has been recorded by Spillmann.

An association of Vincent's microbes complicating a syphilitic chancre of a phagedaenic tendency has been noted by Laimois, and the same association has been observed in soft chancre. A case of thrombosis of the left saphenous vein with gangrenous ulceration of the leg, complicating Vincent's angina, has been recorded by Guinsberg.

I have seen one case in which the uvula was the only part attacked, leading to complete destruction of the posterior portion and tip, a very small part only remaining. Osteomyelitis has been observed by Gilberti, and pernicious anaemia by Mayer.

Symptoms.

In an uncomplicated case the symptoms are sore throat, headache, and pain behind the eyes; there may be no symptoms after the first day or two except slight malaise. In the more severe cases there may be loss of appetite, wasting, and great prostration.

Treatment.

Drugs which have proved of benefit are calomel in repeated small doses, but Vincent states that mercurial treatment aggravates the condition when the patient is not a syphilitic.

Arsenic and a mixture of sodium salicylate and potassium chlorate have been used, and tonics locally. Mercury perchloride and glycerin (1 in 500), silver nitrate, methylene blue, neo-salvarsan, solution or powder applied daily for three days, and frequent gargles of hot hydrogen peroxide have been recommended.

The treatment which Vincent himself finds most effective is a thorough painting with tincture of iodine 6 per cent., after well scrubbing with a tampon to remove the membrane.

A dose of antidiphtherial serum has in some cases proved beneficial. The importance of treating the unaffected side should be borne in mind to prevent recurrence on that side. Salvarsan intravenously (one dose) has been said to modify the disease and prevent recurrence.

The condition must be diagnosed from diphtheria, follicular and other forms of tonsillitis, syphilitic ulceration, primary and tertiary, and scarlet fever. In every case a culture should be made to establish the absence of Loeffler's bacillus.

The Wassermann reaction in Vincent's angina is negative. Certain skin conditions, such as erythematata and bullous eruptions, have been reported, but are probably due to coincident streptococcal infection.

Deductions.

Vincent's angina is a more serious complaint than is often supposed; its general effect on the system is often severe, probably from abundant absorption of toxins. Recurrence may take place even three weeks after the first attack, in which case complications are more liable to occur.

REPORT ON SIX CASES OF TONSILLECTOMY IN DIPHThERIA CARRIERS.

BY

C. C. BALLANTYNE, M.B.TOR., CAPTAIN C.A.M.C.,

AND

B. S. CORNELL, M.B.TOR., LIEUTENANT C.A.M.C.,

DURING June and July, 1917, about fifty cases of diphtheria and diphtheria carriers were treated at Moore Barracks Canadian Hospital, Shorncliffe. The so-called carriers particularly presented a problem in that persistent treatment failed to eliminate the germ. Accordingly, tonsillectomy was resorted to in some of these carriers, and a report of six cases follows. While no originality is claimed for the treatment, the results may perhaps prove interesting.

The tonsils were completely enucleated by the dissection and snare method, and swabs were at once taken from the oral surfaces of the removed tonsils. Then, after thoroughly cleansing the tonsils externally with alcohol and ether, cross sections of the gland were made at three different levels with sterile knives. Swabs were at once taken from the crypts at each of these different levels, the first being one-eighth of an inch beneath the oral surface, the second at the centre of the tonsil, and the third one-eighth of an inch from the capsule. Hypertrophied adenoids, when present, were also removed, sectioned and swabbed in a similar manner. The swabs were immediately planted on Loeffler's blood serum media, incubated for twelve hours, and the resulting growths examined for the *Bacillus diphtheriae*.

CASE I.

Pte. W., admitted suffering from peritonsillar abscess, which readily subsided after incision. On May 24th, as a result of routine swabbing, he was found to be a diphtheria carrier. Until June 12th swabs were invariably positive, and on that date tonsillectomy was performed. Swabs from the tonsils showed:

Right: Surface, positive; top section, middle, and bottom, negative.

Left: Same as right.

Adenoids: Surface and section, positive.

Subsequent throat swabs: Three successive negatives on June 15th, 18th, and 20th.

CASE II.

Pte. M., admitted as a carrier; for six weeks numerous swabs were repeatedly positive. Tonsillectomy on June 12th.

Right: Surface and top section, positive; middle and bottom section, negative.

Left: Surface, top section, and middle, positive; bottom section, negative.

Subsequent throat swabs: Successive negatives on June 15th, 18th, 20th.

CASE III.

Pte. S., admitted with mild tonsillitis, which readily subsided in forty-eight hours without antitoxin. Routine swab June 3rd positive for diphtheria, and repeated subsequent swabs positive. Tonsillectomy June 12th. Swabs from tonsils showed:

Right: Surface, top section, and bottom section, positive; middle section, negative.

Left: Positive throughout.

Three successive negative swabs were not obtained until June 26th, 27th, and 28th.

CASE IV.

Pte. T., admitted June 17th as a carrier. Swabs persistently positive. No constitutional reaction. Tonsillectomy on June 29th. Swabs from tonsils showed:—Right: Positive throughout. Left: Positive throughout. Three successive negatives obtained July 6th, 7th, 9th.

CASE V.

Pte. O'H., admitted May 25th as a diphtheria carrier. Swabs invariably positive. Tonsillectomy June 21st. Swabs from tonsils showed both tonsils strongly positive throughout. Three successive negatives obtained June 23rd, 24th, and 25th.

CASE VI.

Pte. Z., admitted June 5th with mild diphtheria, which readily responded to 12,000 units of antitoxin. Swabs positive persistently till June 29th. Tonsillectomy June 29th. Swabs from tonsils showed both tonsils strongly positive throughout. Successive negatives obtained July 3rd, 4th, and 5th.

In these six cases the operation obviously accomplished the object for which it was undertaken. Although in some the organisms persisted for a few days after operation they disappeared with the healing of the wound. In all these cases saline irrigations and gargles had been continuously used until the time of operation, and their failure is explained by the pathological findings, since in four of the six cases the bacilli were found in the very

depths of the crypts, and surface applications could not be expected to reach them.

Living cultures of *Staphylococcus pyogenes albus* had also been employed as sprays over the tonsils in the hope of outgrowing the diphtheria bacillus, and it was usually found that swabs taken next day were negative for Klebs-Loeffler organisms, but were loaded with staphylococci. The bacilli, however, reappeared in large numbers within a day or two. The probable explanation is that the large number of staphylococci collected on the first swabs had outgrown the bacilli on the media. If, however, the staphylococci outgrew the bacilli on the tonsils, then fresh organisms were soon resupplied from the tonsillar crypts.

CONCLUSIONS.

1. That in apparently normal individuals the *Bacillus diphtheriae* may be harboured in the depths of the tonsillar crypts.

2. That complete enucleation of the tonsils seems to be a successful means for eliminating diphtheria organisms from carriers, although it appears too drastic a measure for routine adoption.

PNEUMOTHORAX WITH HERNIA INTO LEFT PLEURAL CAVITY.

BY

T. H. SANDERSON-WELLS, M.D. LOND., M.R.C.S. ENG.,
L.R.C.P. LOND.,
WEYMOUTH.

THE following case seems sufficiently rare to merit publication:

The patient, aged 26, was admitted to the Princess Christian Hospital, Weymouth, in the late evening of August 21st, complaining of urgent and persistent vomiting. There was a previous history of indigestion for some years; he had never been jaundiced.

The patient was wounded in the chest ten months previously. It was apparently a perforating gunshot wound, followed by the spitting of blood, and fracturing the eighth, ninth, tenth, and eleventh ribs in the left mid-axillary line. The wound was quite healed and sound. The patient had apparently had previous attacks, lasting as much as six hours, but they had become milder during the last three months.

The present attack followed violent exercise on August 17th. Complaint was made of pain in the region of the pylorus; it became very acute forty-eight hours later and had continued ever since. Vomiting occurred thirty-five minutes after the onset of the pain and persisted. The vomit at first was green, but soon became black, with an unpleasant, but not fetid, odour. It recurred during the time he was watched every four minutes in amounts of a few ounces. There had been constipation since the onset of the pain, but he passed flatus on August 20th. He attributed his condition to a diet of fish, but no solid food was taken for forty-eight hours; water swallowed returned almost immediately as black fluid.

On admission he was very collapsed and nearly pulseless, and Dr. Quackenbos, who handled him throughout with the greatest care and skill, administered 10 minims of adrenalin hypodermically. An enema led to the passage of a small quantity of flatus, but no faeces.

The abdomen looked extraordinarily empty, and had an appearance of scaphoid retraction. There was no tenderness, but a little lump to be felt over the pylorus, which was tender and which eventually proved to be an enlarged lobe of the liver. The liver dullness appeared, however, to be normal. Reflexes were present.

There were obvious physical signs of a pneumothorax. The heart's apex beat was visible beneath the right nipple; dullness was present on the left side up to the fourth rib; breath sounds absent; tinkling fluid splash sounds. The patient, whose condition was very bad, was given saline, $\frac{1}{2}$ grain of atropine, and 10 minims of adrenalin.

Operation.

A median incision was made above the umbilicus, and the abdomen explored. The bowel felt, and appeared to be, completely collapsed, and much of the abdominal contents absent. The stomach could not be found, the great omentum and transverse colon had also disappeared. The liver was pushed downwards, and presented in the wound. Further exploration with the hand traced the stomach, omentum, and colon up towards the left half of the diaphragm, and through a hole at the back of the diaphragm into the left pleural cavity. Reduction could not be effected, and the diaphragm was incised from behind forwards, the hole enlarged, and the fingers passed through into the pleural cavity; firm adhesions were discovered between the pleura and its contents, and reduction was obviously impossible. The abdominal wound was quickly closed and the left thorax opened by an osteoplastic resection of the ninth and tenth ribs on the left side in the mid axillary line. Adherent

omentum covered the pleura over the wound and had to be tied off; then through the opening collapsed colon and an enormously dilated stomach presented. A Paul's tube was inserted into the stomach, and 1½ to 2 pints of black fluid drained off. The tube was packed round with gauze, and the skin held in position with a few stitches. The patient was removed to bed, his condition apparently better than when he was brought down. His breathing was much easier, and he seemed very comfortable. He became restless, however, and, despite the exhibition of all usual remedies, he died in the small hours of the morning.

A partial investigation was made the following day by Dr. Quackenbos, who reports as follows:

The heart was situated behind the sternum, the apex being in the parasternal line on the right. An aperture was disclosed in the body of the left diaphragm, which had been enlarged by incision, but which appeared to be of some standing. The liver was displaced downwards, and to the left. The left lung was collapsed, and showed evidence of bronchopneumonia and adhesions at the apex. The stomach was very much enlarged, and, with the transverse colon, the great omentum and four feet of the jejunum, was in the left thorax. The omentum was firmly adherent to the aperture in the diaphragm and elsewhere to the pleura. There were adhesions of the gut to the pleura in places.

The explanation of the condition is difficult.* The old-standing appearance of the hole in the diaphragm might even suggest a congenital weakness, but it seems more likely that the perforating bullet wound which broke the ribs injured the diaphragm, and that the negative pressure in the thorax drew up abdominal contents to take the place of collapsed lung.

Whether, had the patient's condition been better, it might conceivably have been possible to separate the adhesions and reduce the hernia it is difficult to say, but in any case the future function of the organs would not have been satisfactory.

A CASE OF ECTOPIA VISCERUM.

BY

P. R. COOPER, M.D., B.Sc., F.R.C.S.,

BOWDON, CHESHIRE.

THIS case is of sufficient rarity to merit a brief description, especially as the question of surgical intervention arose.

A male child, 16 hours old, was brought to the Altrincham Infirmary by Dr. Young of Broadheath. An umbilical sac or cyst, larger than the abdomen itself, was attached at the umbilicus by a broad pedicle. Its covering was translucent and composed of apparently the same gelatinoid material as the umbilical cord, with which it was incorporated. The sac was fairly tense and contained some darkish fluid, but the wall was not sufficiently transparent to allow of the contents being identified. The child was apparently full time, but not quite of normal size. It was markedly cyanosed and sluggish in its movements, but it evinced no signs of bodily discomfort. The head and limbs were well shaped and apparently normal. The thorax was, however, very narrow and poorly developed. There was very little abdominal wall apart from the umbilical protrusion. The testes were undescended, but the penis and scrotum were well formed.

It was doubted very much whether the condition could be remedied by surgical means, but as the child had practically no chance of survival without surgical intervention, and as the possibility of such intervention could not be ascertained without exploring the contents of the sac, it was decided to operate immediately. Dr. Young gave the anaesthetic, and the abdomen was prepared as for laparotomy. The outer wall of the sac (that is, amnion) was pinched up with forceps, snipped, and a quantity of blood-stained watery fluid released; this reduced the size of the sac quite one-half, and a second covering was exposed by extending the opening in the outer layer. Both layers were extremely thin, membranaceous, and non-vascular, except just at the lower part, where the umbilical vessels proceeded to the stump of the umbilical cord.

On incising the inner covering (peritoneum) the large dark solid mass of the liver at once presented; this was situated entirely outside the abdomen proper. The intestines were also exposed, and were for the most part entirely outside the abdomen proper. The opening of the abdominal wall proper—that is, where the gelatinoid material of the sac abruptly joined the normal skin—formed a ring of about 2 in. diameter, and through this an attempt was made to reduce the extruded viscera. With great difficulty the intestine was put back, but it was found quite impossible to replace the liver. There was not only no room for it inside the abdomen, but there was not enough abdominal wall to have covered it even had one been able to reduce it. All that could be done was to reapply Nature's inadequate covering of the viscera, stitch it in position, and dress the parts aseptically. The child lived for twenty-seven hours after the operation. It had two actions of the bowels, but so far as we know did not pass water. A little fluid was given by the mouth, but vomiting occurred shortly before death, which presumably resulted from cardiac failure.

Necropsy.

The thorax and abdomen were examined *post mortem*. The heart was small, and the foramen ovale unclosed. The lungs were apparently normal and air-containing, light pink, and floated easily. The condition of the liver and intestines was as described above. There was, however, commencing adhesive peritonitis. On exploring the abdominal cavity proper, no kidneys could be felt in the usual place in the loins, but two large kidneys with large suprarenal bodies attached were found pushed up right under the diaphragm, occupying in fact the position of the normal liver. The spleen was well developed. No gall bladder could be found. The testes were very small and occupied a position corresponding to the normal ovaries. The bladder was small and very thick-walled; on cutting into it hardly any cavity was visible, and it contained not more than a drop or two of fluid.

The chief, and to my mind the determining, abnormality in this case was the large size and the unusual position of the kidneys and suprarenals. These had apparently pushed the liver forwards, and thrust it through the umbilicus, where it had been free to grow practically devoid of the usual pressure of surrounding viscera and parietes. It was interesting to note that the liver was much more globular than normal, and presented no flattened edges or surfaces. Its lobes were well developed, and its structure apparently normal, except that no trace of a gall bladder could be found. The faeces, however, afforded distinct evidences of bile. The kidneys and suprarenals were large, but showed no signs of disease, and were certainly not cystic; there was a small peritoneal sac below and in front of each, which was shut off from the peritoneal cavity.

According to Professor Graser (in von Bergmann's *System of Practical Surgery*, which contains the best account of this condition in any textbook I know), the internal layer of the investing wall is probably not part of the parietal peritoneum, but part of the so-called "primitive membrane." These membranes are, of course, not viable. As a rule the children die within a few hours of birth, or later from peritonitis, as the overlying membranes perish. In recent years a number of successful operations have been reported where the defect could be covered.

The FitzPatrick Lectures

ON

MEDICINE IN ENGLAND DURING THE REIGN OF GEORGE III.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By ARNOLD CHAPLIN, M.D., F.R.C.P.,

PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

(Continued from p. 641.)

VI. THE ROYAL COLLEGE OF PHYSICIANS.

I now pass to a consideration of the position of this College with regard to medical progress during the reign of George III. This inquiry embraces the history of the great contest between the Fellows and the Licentiates; it also involves an investigation of the powers conferred by charter upon the College, and the spirit in which they were applied.

The great contest in the College between the Fellows and the Licentiates definitely began in 1752, although the first mutterings of the coming storm were heard as far back as 1746. From that date it dragged on its weary length for more than eighty years, sometimes waxing and sometimes waning, but never really ceasing. Small advances occupied decades for their attainment, and it was not until the beginning of the reign of Queen Victoria that the College could see its way to concede the main great principle for which the Licentiates had contended. For a long time the College was apparently content to accept the existing order of things, and appeared little disposed to move in the direction of any change. Some of the Licentiates, however, were active in their efforts for what they held to be a salutary reform. Amongst these reformers may be mentioned the names of Fothergill, Archer, Wells, Ferris, and Stanger, and no small part of the advancement made in medico-political spheres was due to the persistent advocacy of these men. In season and, it must also be admitted, often out of season, these men urged upon the College the

necessity for reform. To the unwearied perseverance of these men we owe it that this College now rests on the sure foundations of justice and liberality towards the three estates over which it exercises jurisdiction.

Contest of Licentiates and Fellows.

What was this contest between the Fellows and Licentiates? It arose in this way. The charter of the incorporation of the College, and the statutes of 14 and 15 Henry VIII, gave the whole control over the practice of physic into the hands of the College, with the exception that Doctors of Medicine of Oxford and Cambridge might practise in the provinces free from that control. In 1555 the College saw fit to limit the number of its Fellows, and at the same time instituted the grade of Licentiates. In addition to these enactments, the practice had grown up in the College of electing to the Fellowship only those who possessed a degree of Doctor of Medicine from the Universities of Oxford and Cambridge. It is not very clear when the by-law embodying this principle was put into operation, but it was certainly not before 1575. By this practice, therefore, which became the established rule of the College, the whole of its government was placed in the hands of those who were Doctors of Medicine of Oxford or Cambridge, and Doctors of Medicine of other universities were relegated to the grade of Licentiates without any prospect of becoming Fellows or of having any voice in the government of the College. The examination for a Licentiate was the same as that for the candidate for the Fellowship. Outside the walls of the College the Licentiate enjoyed the same privileges and distinction as Fellows, but within the College he was beneath them. This was the position which gave rise to the contest between the Fellows and the Licentiates. Holding that they were the equals of the Fellows, in that they had performed the same exercises, they claimed that they should be admitted to the Fellowship with its rights and privileges.

The contest between the Fellows and Licentiates really began with the demand of Isaac Schomberg to be admitted to the examination for the candidate for the Fellowship. Schomberg had, in defiance of the statutes, practised as a physician in London, and was summoned in 1746 by the Censors Board to present himself for the examination for the Licentiate. This he refused to do, but in 1747, having been entered at Trinity College, Cambridge, he asked to be allowed to practise until he should obtain the M.D. degree. This the College refused, and interdicted him from practice until he had given satisfaction to the College. In 1749 Schomberg obtained the M.D. by royal mandate, and now applied to be examined, but the College refused this until such time that the interdiction was removed. He then offered an apology, which was accepted by some, but not by all. In 1750 he demanded to be examined for the candidate for the Fellowship in virtue of his Cambridge degree. He was allowed to sit, and was adjudged competent, but this decision was negated by a majority, and he was refused admission. Schomberg then took his case to the law courts, but met with no success, the court holding that the College had full power to do as they thought fit. However, in 1765 he was admitted a Licentiate and in 1771 a Fellow. He even attained to the honour of being Censor in 1773 and 1778. This case called forth Sir William Browne's *Indication of the College*, which he intended to read as a reply to the contentions of Schomberg, had the "visitors" decided to hear the case. It is fortunate that no such occasion arose for reading this piece, for it is about the most vain and pedantic effusion that ever proceeded from the pen of that singular personality.

After this, three acts performed by the College contributed largely to the accentuation of the differences between the Fellows and Licentiates. They were as follows: (1) Subsequent to the year 1752 the practice of summoning Licentiates to the College meetings was abandoned. (2) The College passed in 1752 the *Statutum Alterum de Candidatis*, in which it was stated in unmistakable language that no person could become a Fellow unless he held the degree of Doctor of Medicine of either Oxford or Cambridge. (3) In 1765 the statutes and by-laws of the College, after having been revised, were printed for the use of the College officers, thus rendering them available for purposes of investigation.

These acts, but particularly the *Statutum Alterum de Candidatis*, were the cause of the recrudescence of the controversy in 1765. Two parties were formed. The Licentiate maintained that there were many belonging to their body who, although they possessed no Doctorate degree from the sister universities, were nevertheless thoroughly fitted by education and medical attainments to adorn the Fellowship of the College. On the other hand, the thick and thin supporters of the existing order were convinced that no man who had not been educated at either Oxford or Cambridge could be worthy of the honour of the Fellowship. The Licentiate held that the action of the College in excluding them was contrary to the spirit of the statutes in virtue of which the College exercised authority and jurisdiction. They also urged that the curriculum at Oxford and Cambridge scarcely existed for medical students, that the study of medicine in the sister universities was a farce which could be performed in four years by anyone holding a M.A. degree, at the expense of attending a few lectures. This, no doubt, was true with regard to the teaching of medicine, but it must not be forgotten that both Oxford and Cambridge offered considerable facilities for the acquirement of a wide culture. All those intending to study medicine were obliged to graduate in arts, and the scope of the course instituted for the degrees of Bachelor of Arts and Master of Arts has already been described.

To all the contentions of the Licentiate the College turned a deaf ear. They asserted that they knew the form of teaching at Oxford and Cambridge, but were ignorant of the kind of study required at other universities both for arts and medicine. They were satisfied that the only way, in fact, to keep up a high standard of culture and medical knowledge at the College, was to admit those only to the Fellowship who possessed the passport of an education at either Oxford or Cambridge.

The pen was largely used by the opposing sides, and "letters," "addresses," and "reflections" for and against were issued. So high ran the feeling that in 1767 the Licentiate attempted by force to attend the College meetings, and on one occasion succeeded in forcing the doors.

Rex v. Askew.

The whole matter was then tested in the courts in the famous actions of *Rex v. Dr. Askew* and *Rex v. The College*. These trials took place in 1768-9 and 1769-71. They were heard at great length, and arose out of an application by Dr. Letch, Dr. Archer, and Dr. Fothergill for a rule calling upon the Censors to show by what authority they exercise their powers and functions. The cases were heard by Lord Mansfield, Justice Aston, and Justice Yates. The main question was whether or not the College had power to make such by-laws and rules as they thought fit, and this was decided in their favour. But the words of the great Lord Mansfield in delivering judgement were remarkable, and left no doubt that he thought the College was insisting too rigidly on their rights. He cautioned the College "against narrowing their grounds of admission so much, that if even a Boerhaave should be resident here, he could not be admitted to their fellowship. I would recommend the College to take the best advice in reviewing their statutes, and to attend to the design and intention of the Crown and Parliament in their institution. I see a source of great dispute and litigation in them, as they now stand. There has not, it would seem, been due consideration had of the charter, or legal advice in framing the by-laws." As the result of Lord Mansfield's warning, the College passed a new statute by which Licentiate could be admitted to the examination for the candidate for the Fellowship. But since the permission to undergo this examination depended on a majority of the Fellows present, and since after undergoing three such examinations the result of each one, and the final admission, depended on the vote of the majority of Fellows present, the new statute was all but inoperative.

The Case of Dr. Stanger.

On May 16th, 1797, the whole subject was again raised in the court by Dr. Christopher Stanger, who applied to the court for a mandamus commanding the College to show cause why he should not be examined for the candidate for the Fellowship. The case was argued before Lord

Kenyon, and the case for the College was in the able hands of Erskine. Erskine at once cut the ground from under the feet of Stanger by citing the by-law passed after Lord Mansfield's admonition. He said, in effect, that Dr. Stanger could go before the College and be examined, and that the College could elect him a Fellow. Lord Kenyon agreed that the by-law limiting the Fellows to the graduates of Oxford and Cambridge was bad, but since the College had passed a by-law by which Licentiate could be examined for the candidate for the Fellowship he thought the by-laws reasonable. He said, "If any one of the Fellows proposes Dr. Stanger, he goes to that tribunal which I hope and believe is the sanctuary of good faith and honour. . . . They are not bound to admit him; all they are bound to do is to examine him."

After this case had been decided Dr. William Wells determined to put the matter to the test in his own person, in order to see if the College would do that which they had expressed themselves as willing to do before the court—namely, examine for the candidate for the Fellowship any licentiate who was proposed by a Fellow. Accordingly, Dr. David Pitcairn proposed, and Dr. Matthew Baillie seconded, that Dr. Wells should be allowed to present himself for examination. The College, however, refused, thereby deciding that the very by-law on which they relied before the court in May, 1797, was inoperative in September of the same year. Again Dr. Wells was proposed, but again various excuses were resorted to in order to prevent him from being examined. Then he desisted, for persistence was obviously useless. Thus, William Charles Wells, Fellow of the Royal Society, physician to St. Thomas's, and author of the *Essay on Dew*, failed to become a Fellow of the College. His *Letter to Lord Kenyon* dealing with this episode, on account of its manliness, its spirit, its cogent reasoning, and its literary charm, should be read almost as a model of what such specimens of composition should be. A few years later the President caused Dr. Wells to be asked if he still had any desire to become a Fellow, but to this he dryly replied that he had none. This treatment, meted out to Wells by the College, had an unfavourable effect upon its reputation in after-years.

Parliamentary Committee.

In 1834 a Select Committee of the House of Commons sat to inquire into the education and practice of the various branches of the medical profession, and the case of Dr. Wells was made of capital importance by the Committee. Almost every witness was asked his opinion of the fitness of Wells to be a Fellow, and, to their credit, all save one admitted his great scientific and medical abilities as well as his unblemished character. Dr. Macmichael, however, sought to depreciate the position of Wells. But the opinion of Dr. Macmichael is of no moment now, for inexorable Time has passed his judgement.

After the Parliamentary Committee had made a report, the rule regarding the admission of Fellows was amended in such a way that a Licentiate could be admitted to the examination for a candidate for the Fellowship without first becoming a Doctor of Medicine of either Oxford or Cambridge. The contest therefore, which had lasted nearly a century, was ended, and the passions it had raised were stilled.

At the present day the phases through which this contest passed have only an academic interest, and scarcely require notice except as forming part of the medical history under review. It may, however, be observed that out of this contest sprang those wise and enlightened principles which govern at the present time the election of Fellows of this ancient and noble College.

VII. THE MEDICAL PRESS.

I have still to speak of the medical press during the age of George III. In those days no journals existed which dealt with the politics, the aims, and aspirations of the medical profession. When a reformer arose his only method of disseminating his views was by means of "letters," "observations," and "considerations." Most of these tracts, a splendid series of which exists in the College library, are anonymous, and sometimes trivial, but to the student of the period they are often invaluable. In the same way, apart from published books on medical subjects, many short monographs gave

as the first introduction to new ideas and discoveries in medicine. During the reign many attempts were made to establish periodical medical publications. Some of them met with fair success, and flourished for a number of years; but many survived only a short time. The first journal to appear in the reign of George III was *Medical Observations and Enquiries*, in 1757. The next was the *Medical Museum*, published in 1763, and devoted to "Select Cases and Experiments, and Discoveries in Medicine and Pharmacy." After this, in 1767, the *Medical Transactions of the College* were begun, at the instigation of the elder Heberden, and six volumes of these were published, the last appearing in 1820. The *London Medical Journal* was founded in 1781 by Dr. Simmons, who was its first editor, and in 1790 it was transformed into *Medical Facts and Observations*. Simmons was also responsible for the birth of *Medical Commentaries*, which began in 1784 as the journal of the Society for Promoting Medical Knowledge, but it ceased after a few years. *Medical and Chirurgical Knowledge* enjoyed a longer career, beginning in 1793, and lasting until 1818. The next journal to appear was the *Annals of Medicine*, which began in 1796 and survived until 1804. The *London Medical Review and Magazine* existed from 1799 to 1802, and at the same time appeared the *Medical and Physical Journal*, which survived until 1806. In 1806 *Medical Observations* came into being, but was discontinued two years later. In 1808 the *London Medical Review* and the *London Medical and Surgical Spectator* first saw light; the former died in 1811 and the latter in 1809. The *London Medical Reports* and the *London Medical, Surgical, and Pharmaceutical Journal* began in 1814, and both lasted for more than ten years. In addition, the *Transactions of the Medical Society*, the *Medico-Chirurgical Society*, and the *Philosophical Transactions* were in being.

It was not until 1823 that the *Lancet* appeared, and quickly enjoyed a wide popularity. The cause of its success was to be found in its advocacy of medical reform, which was sadly needed, and in the ability with which it was conducted. It not only appealed to the strictly medical mind, but adopted a truculent tone towards existing medical authority, which was relished by the more progressive spirits. Its methods were sometimes questionable, but always undeniably clever, and although such matter as the incomparable "Intercepted Letters" by Wardrop excited great interest, the fact cannot be denied that the good taste of such journalism was very doubtful.

(To be continued.)

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CALCULOUS PYONEPHROSIS: NEPHRECTOMY; LATERAL LIGATION OF THE INFERIOR VENA CAVA: RECOVERY.

THE following case is of special interest at the present time as an instance of recovery following diminution of the calibre of the inferior vena cava.

Mrs. J. was admitted under my care into the Margam Hospital in November, 1916. She was suffering from a swelling in the right hypochondrium and lumbar region, and gave a history of pyuria and intermittent severe attacks of lumbar pain extending over twelve years. A diagnosis of pyonephrosis was made. Cystoscopic examination revealed functional activity only of the left kidney.

Operation.—The lumbar route was chosen. The right kidney was freed and delivered except at the lower pole, where it was fairly firmly adherent to the inferior vena cava. From this structure it was with difficulty cut away, leaving, as was thought, a safe margin of renal (or fibrous) tissue attached laterally to the vein. A few minutes after its complete delivery a sudden rush of venous blood indicated that the wall of the inferior vena cava had given way. The venous trunk was temporarily obliterated digitally, while the hilum was rapidly clamped, and the kidney removed with all speed to gain room. The lumbar wound was quickly enlarged downwards and forwards, and the vena cava brought as near to the surface as possible. An attempt to suture the rent in the vein by Lembert sutures resulted in failure, as the structure was too softened to hold the sutures. Lateral forcepressure was

resorted to. Two pairs of artery forceps, with broad noses and close shanks (to avoid future trouble from intertwining of granulations), were applied in juxtaposition, and their shanks tied together with ribbon gauze. By their bite these narrowed the lumen of the vessel to about two-thirds of its circumference. The hilum was now dealt with. The wound was plugged with gauze, and, with the exception of two through-and-through sutures, was allowed to heal by granulation.

The kidney, completely disorganized, measured 8 in. by 4 in., contained eight large stones, and was merely a bag of pus and venous blood, which had, I believe, leaked into its lower pole from the diseased and eroded inferior vena cava.

The gauze was left *in situ* for three days. After treatment consisted of irrigation with eusol and light plugging. The forceps were allowed to remain for fourteen days, being gently tempted from their lairs from the tenth day onward.

With the exception of an ominous rigor on the fifth day (treated with large doses of aspirin and citric acid), the patient made an uninterrupted recovery.

Seen afterwards, she said that for about a month she suffered from "dropsy" of her legs, which gradually subsided, and that she had lost about four times the usual quantity of blood at each menstrual period, but that the last period showed a decrease.

E. W. M. HUBERT PHILLIPS, M.A.,
M.B., B.S. OXON.,
Surgeon to Miss Talbot's Hospital, Port Talbot.

Reports of Societies.

VALUE AND LIMITATIONS OF SANATORIUM TREATMENT FOR TUBERCULOSIS.

THE discussion on this subject (see *BRITISH MEDICAL JOURNAL*, November 17th, p. 650) was continued at the meeting of the Medical Society of London on November 19th, when the President, Sir ST. CLAIR THOMSON, was in the chair.

Sir RICHARD DOUGLAS POWELL said that the importance of the direct agency of infection in the production of tuberculosis should not be exaggerated. If there were no dirty surroundings and bad habits of life the infection of tuberculosis would almost cease to be operative. The ultimate object of treatment was to help the patient to secure immunity—a power of resistance amounting to a safeguard against fresh attacks of the disease. Some patients would acquire immunity without treatment, and *post-mortem* observations revealed many such cases. Some attained a practical immunity who could by no means be regarded as cured of pulmonary tuberculosis. He had seen many people with considerable lesion in one lung, for many years with chronic cough and expectoration, more or less bacillus-laden, who seemed immune from fresh attack, and ultimately died of some other disease, amongst which cancer and some gouty affections would, he thought, be found relatively prevalent. The disease in such cases was localized and circumscribed by fibrosis. Many cases did well without sanatorium treatment; the margin of difference in favour of sanatorium over general hygienic management was much less than might be expected. On the whole, his firm opinion was that sanatorium treatment was, without doubt, the best, not only in the interests of the community but, in properly chosen cases, also of the individual patient. It would be well to have more subdivisions in sanatoriums, and he suggested (1) a hospital department for acute cases requiring constant nursing and medical treatment; (2) a department for advanced cases; (3) a sanatorium proper with full equipment for cases selected from the two preceding and for incipient and quiescent cases in which immunity was in sight—athletic and industrial exercises would be provided in this department; (4) associated chalets in groups for convalescent and after-care cases. Referring to after-treatment, he said that the patients' prospects depended largely on their own intelligence and care, but also on the condition of life to which they returned. He thought insurance might help, and that some arrangement might be made whereby employees, when definitely attacked with tuberculosis, should receive a certain portion of their

insurance money, which would enable them to undergo prolonged sanatorium treatment and then seek a more outdoor and healthy occupation.

Dr. ARTHUR LATHAM said that both the public and the profession paid too much attention to infectivity. The von Pirquet test showed that 2 per cent. of children of 2 years had had tuberculosis, 55 per cent. of those of 15 years, and pathologists said that by the age of 30 every man and woman had evidence of tuberculous trouble. If the defence was undermined by strain and stress the disease immediately became active, and the increase of tuberculosis during the war might thus be explained. Sanatorium treatment was the best available; it regulated the daily stress and exercise. Sanatoriums should not be filled with those who had a right to be there, but with those who would do well.

Sir ARTHUR NEWSHOLME said that during 1916 there were 53,000 deaths due to tuberculosis in this country. The sanatorium was but a link in the chain of measures of treatment. The first was notification, which was enforced in 1908. By this means (a) the M.O.H. could get control of the environment of the patient; (b) light was thrown on the influence of alcohol as to whether it (1) increased the opportunities for infection, or (2) lowered resistance; (c) co-operation between the M.O.H. and the private practitioner became possible. The work of the tuberculosis officers was of value in consulting with the general practitioner, and in examination of contacts. By examining the relatives it was often possible to get cases early. Sanatoriums were of great value educationally; diminished tendency to relapse, prolonged working life, and decreased danger to the public. Patients often did extremely well in huts in the back garden; it was better for the patients and safer for the families. Cases should be selected for sanatorium treatment on purely medical grounds. Both infectivity and environment were factors, and both were necessary to the production of disease; the resistance and the dosage varied. He considered massive infection of more importance than the other speakers.

Dr. J. J. PERKINS spoke of the causes of the failure of sanatorium treatment. Cases of tuberculosis were not sent up at a sufficiently early stage. Sometimes diagnosis was delayed, and milder measures were first tried; sometimes from kindness the patient was not told of his illness in plain terms. He had seldom met with a refusal to enter a sanatorium provided it was possible in the early stages confidently to hold out hope of recovery. Diagnosis should be pushed further back. Not those patients only with tubercle bacilli in sputa should be sent to a sanatorium, but especially cases of early haemoptysis, tuberculous pleurisy, and cases of progressive emaciation and debility with some pyrexia but few physical signs. He hoped much from change of occupation to an outdoor life after the sanatorium. The National Association for the Prevention of Consumption was founding a colony with the intention of giving these men a thorough grounding in the various branches of outdoor and farm work, in the hope of enabling them to settle on the land.

Dr. F. R. WALTERS was firmly convinced of the great value of sanatorium treatment, and thought the only question was as to how far it could be replaced by dispensary or home treatment. Restoration to health in a sanatorium was usual if the case was suitable and the treatment early, thorough, and prolonged. Suitable cases were those with limited lesions, only moderate constitutional disturbance, no serious complications, originally of fairly good constitution, and without history of massive or virulent infection. It was not usually possible to keep a non-wealthy patient in a sanatorium until he was cured. Three or four months might be needed before graduated exercise was even begun. Relapses were usually caused by disregard of simple rules of life, by late application for treatment, or by premature return to unfavourable conditions. He called attention to the need for physiological subdivision according to febrility and exercise capacity, under the purely anatomical groups, as done in the Surrey County Council statistics. From these it appeared that, if patients applied for treatment before they had lost their full working capacity, two-thirds would be fit for full work twelve months later, whereas of those who waited until they were feverish five times fewer would have full working capacity a year later. Shorter expectation of life in the tuberculous did not show that sanatorium treatment was useless; it might result from a poor constitution *quid*

tubercle, or from unsatisfactory after-conditions. Dr. Walters urged the importance of prompt and more systematic treatment of the febrile tuberculous, health colonies to bridge the gap between sanatoriums and full work, more universal training in sanatorium ways, and greater continuity of treatment.

Dr. B. S. RICHMOND said that he had urged the Bermondsey Borough Council to take municipal beds for the treatment of tuberculous patients. During 1911-12-13 the number of cases sent to the Maitland Sanatorium was 1,345. In June, 1914, only 7 deaths had been reported. Three cases were in touch with the medical officer four years after discharge from the sanatorium. In each case the occupation had been changed. The great difficulty lay in the inability to get suitable occupation, two or three months being spent in a state of semi-starvation looking for work. The way to keep up the immunity gained in a sanatorium was to improve the social condition of the patient, so that he could take advantage of the education received there. The value and limitations of sanatorium treatment should be settled, and it should be made clear that every one was not suitable for sanatoriums, and that the sanatorium was only one link in the chain.

Mr. H. KINGSLEY WOOD, chairman of the London Insurance Committee, said that this was not a single but a mixed problem, and must be treated together with housing, maternity and child welfare, etc. Short periods at a sanatorium were useless; the patient returned to a worse stress than when he left home.

The Right Hon. C. W. BOWERMAN, M.P., secretary of the Trades Union Congress, said that all were aware of the great value to workmen of sanatorium treatment. If the skilled judges in charge of institutions were enabled to follow men discharged as cured, or nearly cured, into their ordinary domestic surroundings one of two things would happen—their hearts would be broken, or they would help to form a band of men determined to improve the housing accommodation in this country.

The discussion was adjourned till November 26th, when Dr. A. Niven Robertson, Dr. Grace Calvert, Dr. Camac Wilkinson, Dr. Mathu, Dr. Henry Ellis, Dr. Jane Walker, Dr. John Sorley, Sir William Osler, and Dr. H. J. Cardale will take part.

Reviews.

THE TREATMENT OF SYPHILIS.

A book dealing with a special province of medicine which has been in familiar use by students and practitioners for twenty-four years may be regarded as having passed beyond the fear or favour of the reviewer. Sir MALCOLM MORRIS's handbook on *Diseases of the Skin*¹ has established itself as a classic. Its popularity is shown by the fact that the first edition, which appeared in 1893, was reprinted in 1894; other editions and reprints have followed each other at fairly short intervals, and the fifth was published in 1911. The sixth edition, in which, as in the fifth, the author has had the advantage of the collaboration of Dr. S. Ernest Dore, is larger by more than two hundred pages than the first, an expansion which may be taken to represent as on an outline map the growth of dermatology in the last quarter of a century.

Among the new features of the book are an article on lichenification, a subject which in previous editions received only incidental mention. The article on that obscure condition, prurigo, the pathology of which is as vague and elusive as the definition of an archdeacon, and those on atrophodermias, have been rewritten, and some additions have been made to the section on the diagnosis of local eruptions. The progress that has been achieved in the therapeutic use of radium and other physical agents is briefly but sufficiently indicated in connexion with the conditions in which they have been found useful. Several new illustrations of the commoner forms of cutaneous disease have been introduced.

But the most important change is in the section on syphilis, which has been enlarged and to some extent

¹ *Diseases of the Skin. An Outline of the Principles and Practice of Dermatology.* By Sir Malcolm Morris, K.C.V.O. Sixth edition, revised by the author with the assistance of S. Ernest Dore, M.D. (Camb.), M.R.C.P. London: Cassell and Co., Ltd. 1917. (Cr. 8vo, pp. xv + 700; 10 colour and 72 black-and-white plates. 12s. net.)

remodelled, with the object of furnishing guidance to those entrusted with the task of carrying into effect the recommendations of the Royal Commission on Venereal Diseases relating to diagnosis and treatment. As Sir Malcolm Morris was a member of that Commission his views on this subject are of particular importance. His conclusion as to treatment is that although mercury is still indispensable, it must now yield the first place to the arsenobenzol compounds. He has seen cases that had been absolutely refractory to mercury or to that agent combined with potassium iodide give way rapidly to salvarsan. The advantages of a combination of both agents are strikingly proved by figures furnished to the Royal Commission by Lieut.-Colonel Gibbard of the Military Hospital, Rochester Row. In 378 cases in which mercury alone was used the percentage of clinical relapses was 33; in 152 cases in which salvarsan and mercury were combined the percentage was only 3.9. A clear account of the method of administration of salvarsan and neo-salvarsan is given, and the author says that as between the two preparations the results obtained by Dr. MacCormac and himself incline him to give the preference to salvarsan as more stable and also somewhat more rapid in its effects. In all primary cases the disease was immediately arrested, and in none which could be followed up did any secondary symptoms, with the exception of sore throat, occur. In secondary cases the lesions of the skin and mucous membranes quickly disappeared. In tertiary cases, even in some that had resisted the vigorous employment of mercury and potassium iodide, lesions of the skin and tongue rapidly healed, and most satisfactory results were obtained in gummata and bone disease, in visceral syphilis, orchitis, and enlarged glands. Sir Malcolm Morris agrees with other observers in stating that little benefit is to be expected from the administration of salvarsan in syphilis of the nervous system. He sums up his experience in the statement that salvarsan may abort syphilis if given in the primary stage and may bring about a permanent cure in later stages; but absolute cure cannot be reckoned on with confidence, and therefore in every case salvarsan should be reinforced by mercury.

INDIAN HYGIENE.

A NOTABLE addition to the large and growing body of Indian sanitary literature has been contributed by Mr. RAMES CHANDRA RAY, L.M.S., whose *Outlines of Hygiene and Public Health*,² recently published, display the same keen assimilation, effective condensation, and clear methodical exposition which are so conspicuously manifested in his *Outlines of Medical Jurisprudence*, a treatise which has reached its fourth edition, and to which the present work is designed to be a companion and complement, "so as to complete the subject of State medicine." The author states in his preface that he has "written this book with a special eye to tropical, and particularly Indian, conditions, and has meant it to be used by the university candidate during his pupilage, and by him as a practical sanitarian during the practice of his profession." "Sanitation," he adds, "now looms large in the university curriculum as well as in the daily practice of the medical profession."

All conditions bearing upon personal and public health are set forth systematically, and, by the use of various types, figures, and letters, subjects are logically arranged and discussed and rendered easy of reference. Portions of the book "useful to sanitary officers" are specially indicated by a note appended to the table of contents, and parts which the student need not read for examinations are printed in small type. The index might be amplified and improved.

The sanitary faults and shortcomings of Indian people and communities are frankly pointed out and remedies clearly prescribed. Special features of the work are: A detailed description of biological sewage purification and its practical adoption in India; a classified list of mineral springs in India which are little known and might with advantage be further investigated; a complete list of human parasites, including an account of their life-history; full information regarding Indian climates and health resorts; a sanitary gazetteer of districts and hill stations

throughout the Indian empire. This last is somewhat sketchy, and might be amplified and elaborated, but this process would probably be inconsistent with the size and scope of the volume. The chapters on infections and infectious diseases are well done and up to date. The statistical chapter is devoted to general principles and methods. Some information regarding births, deaths, and marriages and the incidence and mortality of special diseases in different parts of India would be interesting, and statistical evidence of the reduction of sickness and mortality among soldiers, prisoners, and the general population by means of sanitary reforms might be added in a future edition. A chapter on sanitary laws and regulations in India, which are very cursorily referred to, might also be embodied in the work. There are several useful illustrations and ingenious tables throughout the book, and arithmetical and mathematical details of a more abstruse character appertaining to various subjects are very properly relegated to an appendix.

Altogether these *Outlines* are well adapted for the purposes for which they have been compiled. The printing and get up of the volume are creditable to the Nababibhakar Press.

NOTES ON BOOKS.

AMONG the duties undertaken by the Universities Bureau of the British Empire, which was founded in 1912, has been the publication of a *Yearbook of the Universities of the Empire*.³ For reasons of economy it was decided not to issue the *Yearbook* last year, but publication has now been resumed as it was held that suspension for more than two years would defeat the purpose of such a chronicle. The present edition thus appears as the *Yearbook* for 1916 and 1917. The editor is Dr. Alex Hill, honorary secretary of the Bureau. The general information published in the last edition with regard to conditions of admission, faculties, degrees, scholarships, and so on, has not been repeated, since few changes have been made in the regulations of the universities during the war; but the outstanding academic events of the past two years are briefly recorded, and the lists of office-bearers in the various universities and their constituent colleges have been carefully revised. There is also a full index to the names of professors, lecturers, and demonstrators mentioned throughout the volume. This *Yearbook* will be found a very useful directory to the fifty-six universities of the British Empire.

School managers, school teachers, and all interested in the education of the poor should read *The School Camp*,⁴ a book in which much light is thrown on the uses and abuses of school clinics and open-air schools. Here will be found, set out in most attractive style, an account of what has been done at Bradford and other cities during the last decade to remove the disabilities that come to the children of poverty, and make even the best teaching difficult or impossible. It contains chapters on these disabilities, and on the way in which they may be relieved or neutralized by improved school environment and camps—baby camps, girls' camps, and boys' camps—and on the many things that yet remain to be done to improve the education of the children of the poor. Miss McMillan has intuition, and writes with feeling and the most profound sympathy for children.

In *The Framework of a Lasting Peace*⁵ Mr. LEONARD S. WOOLF surveys the subject of international organization for preventing war. He compares certain published programmes, laying emphasis upon the matters in which there is agreement rather than upon the differences between the various schemes. He begins with the obvious fact that mankind has only two methods for regulating the relations of groups as well as of individuals: one is force, and the other (which he defines as government and organization) is the laying down of general rules. Before the war, regulation of international relations by general rules had reached a considerable degree of development, whether under the name of international law, or under some less imposing title. Mr. Woolf maintains that whatever name may be given to these rules the fact of their existence and influence cannot be altered, for they are applied daily,

³ *The Yearbook of the Universities of the Empire, 1916 and 1917.* London: H. Jenkins, Ltd. 1917. (Demy 8vo, pp. 412. 7s. 6d.)

⁴ *The Camp School.* By Margaret McMillan, C.B.E. London: George Allen and Unwin, Ltd. 1917. (Cr. 8vo, pp. 178. 3s. 6d. net.)

⁵ *The Framework of a Lasting Peace.* Edited by L. S. Woolf. London: George Allen and Unwin, Ltd. 1917. (Demy 8vo, pp. 154. 4s. 6d.)

² *Outlines of Hygiene and Public Health.* For Students, Sanitary Officers, and Practitioners. By Rames Chandra Ray, L.M.S. Calcutta: Hare Pharmacy. (Cr. 8vo, pp. ii + 512.)

consciously or unconsciously, in nine-tenths of all international commerce and intercourse. As recognition of this must underlie any scheme of international government to prevent war, the problem is to establish rules which will be generally accepted and applicable to all the relations between the groups concerned. The task is thus twofold: there is the laying down of general rules, and there is the application of them to particular cases. A point brought out in this analysis of schemes is that none of them goes beyond the co-ordination of already existing methods of settling international disputes and regulating international relations. Mr. Woolf suggests that a small permanent body will be needed with the sole duty of watching over and promoting the fulfilment of the pacific obligations undertaken by the signatory Powers.

WAR EMERGENCY FORMULARY.

ADDENDUM TO THE BRITISH PHARMACEUTICAL CODEX.

In our issue of August 11th, when commenting upon the withdrawal of certain galenic preparations containing sugar and glycerin from the *British Pharmacopoeia*, we mentioned the fact that a supplement to the *British Pharmaceutical Codex* would shortly be issued containing alternative formulae for many of the preparations most commonly used. After somewhat more delay than was expected, this supplement has now been published. It contains alternative formulae for forty-three of the deleted B.P. galenicals, and also eighty-eight others which are intended as substitutes for commonly used preparations of the *Codex* which contain glycerin or sugar. The formulae have been approved by representatives of the British Medical Association, and by agreement with the Pharmaceutical Society the Central List of Stock Mixtures has been revised and the new alternative formulae have been substituted for those preparations containing glycerin or sugar which have not been deleted altogether. It has also been mutually agreed to recommend that as from December next the new preparations should be used in all new prescriptions, and that all local formularies should be revised on the appointed date, the preparations of the *Addendum* being substituted for those deleted from the *British Pharmacopoeia*.

The new preparations are to be distinguished by the addition of the initials W.E.F. (War Emergency Formula) to the name of the original preparation, the titles of the ex-pharmacopoeial and *Codex* preparations having been retained in all cases; it will only be necessary that prescribers and dispensers be instructed by Local Panel and Pharmaceutical Committees respectively that the new alternative formulae must always be used in the place of the original ones.

So far, therefore, as National Health Insurance is concerned the position is perfectly clear, and if the above recommendations are acted upon by the local committees the formulae in the *Addendum* will necessarily be used in dispensing all prescriptions containing the preparations in question. The position with respect to prescriptions for private patients is, however, somewhat different, and in these cases it unfortunately appears very doubtful whether the letters W.E.F. are sufficiently distinctive to entail any obligation on the part of the dispenser to dispense *Addendum* preparations exclusively, especially as the same letters were suggested some time ago for use in designating similar private formulae. As the greatest possible degree of uniformity is obviously desirable, we suggest that, in order to prevent any misunderstanding, the abbreviation Cod. should be used in addition to W.E.F. in all private prescriptions which are likely to be dispensed by pharmacists not known to the prescriber.

The formulae themselves do not appear to require much comment. The substitutes for ex-pharmacopoeial preparations are distinguished by an asterisk after the title, but in the case of two preparations (*extractum gossypii radice corticis liquidum* and *syrupus rosae*) the asterisks have been omitted in the copy examined, no doubt by a printer's error. The sugar or syrup in the original formulae is sometimes merely omitted and in other cases is replaced by glucose or by a preparation to which the title "syrup substitute" is given and which consists of a tragacanth mucilage containing 0.5 per cent. of chloroform. Glycerin is either simply deleted or its place is taken by alcohol, glucose, or syrup substitute, according to whether

it is desired to imitate the preservative action of glycerin or its physical characters. In a series of memoranda for prescribers and dispensers it is noted that the physical properties of many of the preparations are necessarily somewhat altered, although their efficiency is not impaired, and also that some preparations may not keep quite so well as heretofore; in doubtful cases it may therefore be advisable to dispense them in a comparatively fresh state. Doses remain approximately the same in all cases, but the strengths of the ingredients in certain of the *Glycerina* have been reduced, as the removal of the glycerin results in the same therapeutic effect being obtained with a smaller proportion of the principal medicament. The only error of any importance which has been committed consists in the direction to use maize or rice starch in compound liquorice powder, an act which is illegal as it is now forbidden to use these starches in any but articles of food. In practice this error will, no doubt, be rectified by the substitution of potato starch.

"STATISTICAL WIRE-PULLING."

We have received the following letter:

SIR,

I do not propose to discuss the polite references in your leader of November 10th to my alleged "statistical incompetence and controversial blindness," etc. But I would remind you that in the three points you urge against me you have not succeeded in getting rid of my arguments.

In regard to anthrax, it remains unchallenged that Selavo's serum (used in practically every case) has not succeeded in reducing the number of deaths. I do not dispute that the numbers to the living population are infinitesimally small; hence it is that the rates per million cannot be given. The fact that there have been recent cases of anthrax due to infected hair does not affect my position or my argument. You wish to know, in order to "check my figure," the number of years I have averaged the anthrax mortality prior to the introduction of Selavo's serum. I took the quinquennium 1891-95, immediately preceding that of 1896-1900, in the middle of which (between 1898-99) Selavo's serum was introduced into this country. It averages 8 per annum. If we take the whole fifteen years which my figures cover—1901-15—the average mortality is, in round figures, 16 per annum, and if a corresponding fifteen years are taken immediately prior to the introduction of the serum—namely, from 1885 to 1897—the average works out at 9. The statistics in quinquennia as furnished by the Registrar-General are as follows:

Prior to Introduction of Serum.			Subsequent to Introduction of Serum.			
1881-5.	1886-90.	1891-5.	1895-1900.	1901-5.	1905-10.	1911-15.
12	9	8	15	17	17	14

These figures, I think, sufficiently justify my conclusions.

You complain that I omit measles from my tables, and you select certain years (from 1901 to 1915) in order to show how this disease has increased. Had I adopted this course I should probably have been charged with further delinquencies similar to those you have already laid at my door. While quoting the year 1915 as evidence of the increase of measles, you omit to say that the year previous (1914) showed, with two exceptions, the lowest annual death-rate on record.

I do not profess to understand all the mysteries of epidemiology, with its exacerbations and remissions, but I do believe, and statistical history provides a basis for my belief, that in proportion as sanitary laws are efficiently administered, so the severity of epidemic diseases as a whole decreases. This is illustrated even in the case of measles, which, for the decennium 1901-10, showed a lower average death-rate than for half a century previously. The sudden rise from 247 per million in 1914 to 462 in 1915 may or may not arrest the down-grade of the next average decennial figure, but even the last quinquennial average of 343 is well under the totals of the decennia 1881-1900.

Now I am quite alive to the fact that the measles death-rate has not declined proportionately to that of other epidemic diseases, and the reason for this delay constitutes a subject of considerable interest and speculation. Measles

is one of the mild "zymotics" (so-called) which lingers among children now that the coarser "zymotics" bred of the grosser insanitary conditions of earlier years have passed away. It cannot therefore be expected to decline with such rapidity as its fellows. In the decades 1861-70 and 1871-80 the death-rates per million were 393 and 334 respectively. In 1875 the Public Health Act was passed, and with it came an enormous decline in small-pox and scarlet fever. In the decennium following the passing of that beneficent Act small-pox mortality dropped from 230 per million to 44 per million, and has been declining ever since. Scarlet fever also dropped from 649 to 312, and is still declining. But measles, instead of declining, showed a tendency to increase, for the death-rate per million rose from 334 to 406 in 1881-90, and to 414 in 1891-1900. Then came a drop (1901-1910) to 309, and I believe we shall find in the next decennium that a still further decline will be manifested.

But, it will naturally be asked, Why did measles mortality rise during the years 1880-1900, at a time when small-pox and scarlet fever so manifestly declined? My own opinion is (and I give it for what it is worth) that two chief factors were concerned in the increase: (1) The shifting on to measles of some part of the enormous decline of small-pox and scarlet fever. (2) The overcrowding of the elementary schools in the early years of the passing of the Education Act.

I would respectfully suggest that the selection of certain years is not in accordance with statistical accuracy, but an average taken over a number of years, allowing for exacerbations and remissions, can alone furnish an average upon which a sound judgement can be based.

The wire-pulling of commercial interests behind the preparation of salvarsan is notorious everywhere outside the editorial office of the BRITISH MEDICAL JOURNAL. The same may be said of all the vaccines and serums so persistently advertised. Nor is it the first time that this has been stated, for even in the presidential address of the Section of State Medicine, at the Annual Meeting of the British Medical Association itself, these words have been heard: "The whole of bacteriological theory and practice is steeped with commercial interests." Dr. George Wilson, afterwards a member of the Royal Commission on Vivisection, said this in 1889. If it was true then, how much more powerful must the commercial element be now! The morbid sensationalism among society ladies and panic-stricken gentlemen on public platforms in connexion with syphilis (which, fortunately, has now fizzled out) is shown to have been ridiculous by the statistics I have published. We all know "the statistics are incomplete": all the more reason, then, for the sensation-mongers to have taken a little less for granted, inasmuch as the only statistics available do not bear out their assumptions any more than they justify the equally sensational claim in certain quarters as to the life-saving properties of salvarsan.

I remember an editorial remark published in your columns some years ago, which said: "Fashions in medicine have their little day and cease to be. Our back numbers are the graveyards of discarded theories." It may not be long before Scavo's serum, salvarsan, and a few other fashionable drugs of an equally questionable and dangerous type, which I have dealt with in my statistical pamphlet, may find a similar resting place.

I am, Sir, yours faithfully.

WALTER R. HADWEN, M.D.

Gloucester, November 13th, 1917.

We will make one more attempt to explain the nature of the errors in Dr. Hadwen's statistical methods, though without much expectation of convincing him that he is blundering. In the first place, we pointed out that the fluctuations of the annual numbers of deaths from anthrax were of the order attributable to the operations of chance, and that no statistically valid argument as to a real increase or decrease of deaths could be based upon such figures. This elementary proposition is still, it seems, unintelligible to Dr. Hadwen. He now contrasts an annual average of nine deaths taken over fifteen years with one of sixteen. If Dr. Hadwen consults a textbook of statistical method he will find that when the number of "successes" is very small in proportion to the number of "trials" (in the present case deaths from anthrax are "successes" and the population at risk represents the number of trials), the approximate measure of chance fluctuations in the number of successes is the square root of that number. Hence the difference between the two averages—seven—is subject to an error of sampling of the order of ± 5 , and is therefore entirely without significance.

An application of the same method to Dr. Hadwen's full series leads to the same conclusion. Dr. Hadwen, indeed, seems to have a faint suspicion that his suggestion of a significant increase in the number of deaths was rash, and naively remarks that "it remains unchallenged that Scavo's serum (used in practically every case) has not succeeded in reducing the number of deaths." This remark reveals a lower depth of statistical incompetence than even we (and we were not optimistic) had suspected to exist within the precincts of the British Union for the Abolition of Vivisection. It would almost seem that Dr. Hadwen supposes a valid inference can be drawn as to the effects of a method of treatment, *without knowledge of the numbers of cases which were and were not so treated, together with the respective deaths.*

Dr. Hadwen next passes to a more congenial task. We are said to have selected certain years for the purpose of showing that measles has increased. What we really said was that the death-rate from measles has not declined, and we merely quoted the rates for the first year of Dr. Hadwen's series and thereafter at intervals of five years; we could not quote the 1916 figure, which should have concluded the series, because the report containing it is not yet published, and had therefore to insert 1915. If Dr. Hadwen prefers the quinquennial averages for his series, we are pleased to give them; they are, 1901-5, 327; 1906-10, 291; 1911-15, 343. The gravamen of our criticism on this head was that, while dilating upon the decline of scarlet fever, Dr. Hadwen omitted all reference to the course of an equally important zymotic of obscure origin.

Finally, as to syphilis. Dr. Hadwen wrote, "the death-rate, which had been gradually going down, suddenly increased and grew higher and higher until 1915, when large numbers of men went to the war, and would be included in the military statistics." He wrote this although he knew, and now admits that he knew, that the official records of deaths from venereal diseases were altogether incomplete. Dr. Stevenson (Appendix I, Final Report of the Royal Commission on Venereal Diseases) said: "The worthlessness of the returns as an absolute statement of the number of deaths from venereal disease scarcely requires demonstration." Dr. Stevenson thought that the recorded figures might be some index of a decline, but that the considerations in support of even this were indecisive.

Knowing these limitations and objections, Dr. Hadwen published the unqualified statement we have quoted, and in his letter to us has the hardihood to assert that the views of those who believe syphilis to be an evil of national importance are instances of morbid sensationalism proved to be ridiculous by the statistics he has published.

In sole support of the charge that his professional colleagues are the accomplices or the tools of commercial adventurers, Dr. Hadwen cites an *obiter dictum* uttered twenty-eight years ago, which has been part of the stock-in-trade of the opponents of modern scientific medicine ever since.

Although we grudge space devoted to the exposure of mere blunders in statistical reasoning, we might, in the interests of science, think it our duty to continue such exposures. But the reiteration of charges offensive to the honour of professional men puts a controversialist beyond the pale of discussion. Dr. Hadwen will doubtless continue his career of misrepresentation, but it cannot be in our columns.

THE report of a commission appointed by the French Parliament in April, 1916, to consider the appointments open to men discharged from the army on account of wounds or disease contracted in the war has recently been published. It gives an unexpectedly favourable view of the situation. It was feared that the majority of such men would be anxious to get into Government employment, and preparations had been made to provide a number of openings for them. There have been a great many more applications than vacancies for the position of letter carrier and receiver of direct taxes, and there has also been a great run on the post of lock-keeper, but for all other berths comparatively few applications have been made. Thus, for 70 clerkships in the State railways there were only 9 applicants, and only 24 for 293 places in the Paris *octroi*. The conclusion of the committee is that the majority of discharged men wish to make their own way in industry, agriculture, or trade.

British Medical Journal.

SATURDAY, NOVEMBER 24TH, 1917.

THE TRANSFUSION OF WHOLE BLOOD.

THE value of the transfusion of blood in cases of severe haemorrhage has not hitherto received, perhaps, all the attention it deserves. There can be no doubt as to the fact that loss of blood is one of the chief factors in bringing about a fatal issue in the wounded in war. This has been shown both in wounds of the trunk and in those of the extremities. It is notoriously true, for example, in abdominal cases, as proved by the statistical records recently published concerning such injuries. The haemorrhage leading to a fatal issue may be primary or secondary. Methods of meeting the emergency have largely been restricted to efforts to control the bleeding points and the injection of normal salt solution into the depleted circulation, together with such subsidiary measures as maintaining the body heat, and complete rest in a quiet darkened room. The ideal therapeutic measure would obviously be the replacement of the lost blood.

Prior to the war this subject received much more extensive consideration in the United States and Canada than in this country. While it is true that the transference of blood from one individual to another has been attempted from time to time for centuries, the earlier methods were beset by so many technical difficulties that they were abandoned. In modern times these technical difficulties have been largely overcome by the work of Carrel and Crile, while the more general application of transfusion has been rendered possible by the introduction of the use of syringes with cannulae and by the citrate method. Of these may be mentioned Kimpton's citrate method, in which a glass cylinder is used to mix the blood and citrate, and Lindeman's syringe and cannula apparatus. Various modifications of these methods have been introduced by other surgeons. The instrument introduced by Unger, consisting of a two-way stopcock apparatus, is ingenious and answers the purpose well.

The earlier cases of transfusion of blood during the present war were reported by Canadians. Thus Bruce Robertson reported a series of four cases in France in the *BRITISH MEDICAL JOURNAL* of July 8th, 1916. Primrose and Ryerson reported two cases from No. 4 Canadian General Hospital at Salonica in the *BRITISH MEDICAL JOURNAL* of September 16th, 1916. Subsequently, we are told, six other cases were transfused in this unit at Salonica. An instructive series of sixteen cases was reported from the British front, by Fullerton, Dreyer, and Bazett.¹ In the present number of the *JOURNAL* will be found a second series of thirty-six cases reported from France by Bruce Robertson. A careful study of these cases will convince the reader of the enormous value of the transfusion of blood in cases of severe haemorrhage, and the subject is clearly worth the very serious consideration of those at work in casualty clearing stations and advanced operating centres. We cannot discuss all the various phases of the question, but sufficient evidence is forthcoming from the papers

already published to show that transfused blood will replace and assume the part of the blood lost by one who has suffered severe haemorrhage. The coagulability of the blood is increased, and the patient acquires increased resistance to infection; shock is diminished, and the case becomes a greatly improved surgical risk.

The method suggested by Fullerton, Dreyer, and Bazett, and that described in this issue by Hull, are ingenious devices for direct transfusion, but all such direct methods are open to the objection that the amount of blood transfused cannot be measured. It is difficult to estimate the amount from the symptoms shown by the donor; for example, he may faint because of the psychological effect of his surroundings, and not because of loss of blood. Another objection to the direct method is the constrained position in which the recipient and donor must lie during the operation. They cannot alter their relative position to one another; this restriction of movement is not necessary with either the syringe or citrate method. In a case of very severe haemorrhage this may be a matter of no little importance for the patient, for whom rest is so essential. The donor does not appear to suffer any permanent ill effect. The usual amount of blood transferred has been from 700 to 1,000 c.cm. Robertson mentions five cases of the injection of 1,200 c.cm., but does not say whether in each case all the blood came from the one donor. It may be worth while, therefore, to say that we know of an instance in which 1,140 c.cm. were withdrawn from one donor without causing him any serious inconvenience.

Particular attention may be called to the conclusion at which Colonel Gordon Watson has arrived after seeing Major Robertson's results. He says: "Transfusion of blood after primary haemorrhage is a life-saving device of the greatest value and enables urgent operations to be successfully performed under conditions otherwise hopeless."

The dangers of transfusion are twofold—first, the transmission of some infectious disease, and secondly, the transfusion of blood having unsuitable biological characters. The first danger may be avoided by a careful clinical examination of the donor of the blood, syphilis being excluded by a Wassermann test; the second by determining the iso-agglutinin characteristics of both donor and recipient, and selecting a donor having a blood with iso-agglutination reactions like or suitable to the recipient, preferably the former. Although the most severe reactions, occasionally fatal, following transfusion occur when the serum of the recipient agglutinates the corpuscles of the donor (Ottenberg), minor reactions of agglutination and haemolysis may be observed when other unsuitable donors are taken; they markedly lessen the therapeutic value of the transferred blood. It is therefore important to obtain a suitable donor previous to any attempt at transfusion. Human bloods possess two iso-agglutinins and two iso-haemolysins, and may be divided into definite groups according to their iso-agglutination and iso-haemolytic reactions.

The ideal condition for transfusion is that the bloods of the donor and the recipient should belong to the same group. The simplest complete method for testing the blood previous to transfusion is perhaps that recently described by Moss.² Two standard human serums, each containing a different iso-agglutinin, are kept in stock in the laboratory. At the time of the transfusion a drop of blood is obtained in a test tube containing 8 to 10 c.cm. of normal saline, from the recipient and each of the possible donors. Having shaken the tubes containing

¹ *Lancet*, May 12th, 1917.

² *Journal of the American Medical Association*, June 23rd, 1917.

the different blood suspensions, to ensure thorough mixing, a drop of each blood suspension is mixed with a drop of each of the two standard serums on a hanging drop slide and incubated for one hour at 37° C. The preparations at the end of an hour are examined under the microscope and the presence or absence of agglutination noted. A suitable donor is indicated by the blood showing a similar reaction to that of the recipient.

In the present issue of the JOURNAL Major Lee discusses the selection of suitable donors for transfusion and describes two very simple methods of testing for them. The first test simply determines whether or not the donor's blood is agglutinated by the recipient's serum. By this method the severest reaction following the transfusion of blood from unsuitable donors is prevented. The second method is based on the same principle as that suggested by Moss. As pointed out in Lee's paper, the blood groups of both donor and recipient may be determined by this method, and the selection of an ideal donor—that is, one belonging to the same blood group as the patient—may be made.

At the front, where transfusion of blood is of the greatest value, where laboratory facilities are often not available, and the demand is as immediate as it is imperative, it is fully justifiable to take the risk and proceed with the transfusion without investigating the characteristic features of the blood.

LEGISLATIVE CROSS CURRENTS.

THE similarity between the present position of the proposal for a Ministry of Health and that of the Education Bill is rather striking. The principles of both command general acceptance, both have strong supporters within the Government and in Parliament, yet both hang fire. The reason in each case seems to be twofold: first, the dislike of local authorities, and the constituencies by which they are elected, for anything that savours of the increase of centralization and the diminution of local self-government; and, secondly, the contrary opinion of many who believe in the advantages of the increase of centralization and of ministerial powers of direction and control. This last opinion, not unnaturally perhaps, commends itself to permanent officials, and the politician has also to take account of the distaste with which every ministry views any proposal for handing over any of its departments or powers to any other.

The strength of these contrary currents is for the moment so nearly equal that a sort of eddy of opinions is produced from which the distracted minister seeks to escape by way of concessions designed to conciliate the one side or the other. Mr. H. A. L. Fisher, it is said, has succeeded in coming to an understanding with bodies representing the local education authorities, which leads him to hope that they will not oppose the second reading of the Education Bill, and that an agreement will be reached as to amendments in committee.

The controversy with regard to both schemes may seem for the moment to be about matters of detail, but the difference between the two ways of thinking is deep. Both have existed from a very early state of European civilization. There have always been those who, having conceived an ideal state, are so impressed by the truth and beauty of their concept that they wish to apply it at once to every relation of life. Often they show themselves intolerant; in a ruder age they sent their opponents to the scaffold or the stake; in a gentler age they in Germany sent them to prison, in France they dubbed them reactionaries,

and in this country, dropping as they believed into French, they said their opponents followed a policy of *laissez faire*. There have always also been people of the other way of thinking, who have looked at social problems from what may be called the biological point of view. They have had regard to the history of the growth of institutions and the characters and special capabilities of different races, seeking to encourage and if possible to hasten the natural development, but not to cut across the stem in order to graft on to it a new top.

Among philosophers very respectable opinions could be quoted on either side, but it may be doubted whether abstract speculation can help us in the matter, so that we have to rely upon practical experience of the two plans at work. The influence of the German *Kultur* in this country has been wider and deeper than most of us are perhaps now willing to admit. Quite unconscious of the source of their inspiration large numbers of energetic people, animated by altruistic sentiments, have become strongly imbued with the idea of the merits of the centralized state. They desire the beneficent despotism, not indeed of a Caesar or Kaiser, but of an all-embracing committee called the Government or the State. They shut the eyes of the mind to the indisputable fact that that is not the road along which the other culture, that of which this country is the mother, has walked in the Overseas Dominions or in the United States of America—the culture for which these nations, with allies who have gone the same road, are now fighting.

Those who take what we have ventured for convenience to call the biological view will be attracted by the arguments which Dr. W. A. Brend stated at large in a book recently reviewed in our columns, and some who have not read the book will be grateful to have their attention directed to a briefer statement he has published in the current *Edinburgh Review*. The main suggestion which seems to arise out of the consideration he has given to the history of the present position of public health administration and inquiry is that the natural line of growth is towards the strengthening and consolidation of local administration rather than towards increased centralization. The Prime Minister told a deputation from Scotland the other day that all-round devolution was necessary. He was speaking of the necessity of delegating from the Imperial Parliament to local bodies questions which are purely local, but the principle applies, whether the central authority be Parliament or a ministry. Dr. Brend urges the strengthening of local administration on two grounds; the first is that most of the larger local authorities are now fully alive to their responsibilities, and many county boroughs are displaying zeal and energy in attacking the causes of disease and improving the conditions of health. He cannot defend some of the smaller urban and rural authorities, and their supineness in public health matters is undoubtedly largely responsible for the willingness of so many persons to accept the idea of increased centralization. But his second ground for strengthening the local authorities is that experience shows that a central authority may display neglect and incompetence as great as that of a rural district council, and that a central authority has, in fact, often hindered rather than assisted the progress of schemes for improvements formulated by the large county boroughs. The record of the Local Government Board in this connexion is far from satisfactory: its presidency has been the mounting block for politicians who have ridden away at the first chance; its complex affairs, in which the prevention of disease has always formed a subordinate part, has been administered by a

secretariat consisting of able officials, skilled in precedents and the interpretation of laws and rules, but wholly untrained in knowledge of the sciences from which these laws and rules take origin. They are under no obligation to consult medical or sanitary experts, or to accept their recommendations, for by a vice of constitution inherent from its earliest days—a vice due to a political piece of jugglery—its medical department is in a place of inferiority, starved of staff and of funds.

Dr. Brend makes a courageous attempt to distinguish between those duties which can most usefully be assigned to a central authority and those which properly belong to the local authority. Consideration of the duties which should fall upon a central authority at once raises the question whether a really efficient Ministry of Health could be obtained by taking over the public health and medical branches of existing Government departments. It is quite easy to make a good story by the enumeration of the many central departments which have to do with matters affecting the health of the people, but we must remember that they came into existence because the various ministries found a need of skilled advice on public health and medical questions. If they were all taken over to-morrow by a new ministry, the other ministries which must remain concerned with public health and medical questions would be compelled either to appoint new medical advisers for themselves or be continually referring a large proportion of important questions coming before them to the Ministry of Health. Apparently in any case the India Office, the Colonial Office, the Foreign Office, and the Navy and the Army must be left outside the scope of the Ministry of Health and must each have its own medical and sanitary departments. Dr. Brend's contention, as we understand it, is that the main duty of a central ministry of health should be research into general questions, and the unbiassed criticism of results. There are two lines of research: the one clinical and laboratory—such work as the Medical Research Committee has been doing for the Army—and the other statistical. Probably everybody will agree with Dr. Brend that the most complete and reliable statistical work in public health at present conducted in this country is that carried out by the Registrar-General for England and Wales, and he is thus led to propose that the office of the Registrar-General should be enlarged so as to form the one central statistical office for all matters relating to public health, which might then be called the Ministry of Health. The office he proposes would continually investigate the causes and distribution of disease, and would subject to expert criticism all public health measures before they were introduced into Parliament. It would need a staff of experts in every branch of medical science and hygiene. Other matters which would be administered centrally are the Acts for the prevention of food adulteration, for the notification of infectious diseases, and the regulation of sanitary conditions in factories; the control of these matters might remain where it is. With regard to local administration, he suggests the formation of a local health council nominated by elected local bodies, one-half by the local authority, which would mean the transference of its sanitary committee to the new authority, one-quarter by boards of guardians, and the remainder by managers of local hospitals and by the Ministry of Health.

There is, it will be seen, considerable resemblance between these proposals for local administration and those put forward by the British Medical Association,

but there is this great difference—that Dr. Brend does not provide for the representation of the local medical profession on the local health council.

THE LIFE OF LISTER.

THE biography of Lord Lister,¹ which Sir Rickman Godlee undertook to write soon after his uncle's death in February, 1912, was published this week. It is a handsome volume, in large octavo, illustrated by several portraits of Lord Lister himself, and of his grandfather, his father, his mother, his wife, and his father-in-law, James Syme. Sir Rickman Godlee had many qualifications for this task. In his student days he was able to compare the old system of surgery, then in full swing at University College Hospital, with Lister's practice in Edinburgh; he had access to his uncle's notebooks, many pages of which he wrote to his dictation, while for a time he was almost a daily witness of what was taking place in Lister's laboratory. Sir Rickman Godlee modestly suggests that the fact that he was so nearly associated with Lord Lister, who watched over his early career with paternal care, was a drawback to him in his task, because it may have obscured the true sense of proportion. In so far as a first glance at the volume goes, this pitfall of the biographer has been avoided, and it was perhaps not so dangerous as it might have been in many cases, for Lister's life was largely lived in the laboratory, the operating room, and the wards of hospitals. Perhaps the most dramatic scene in Lister's career was at the public celebration of Pasteur's seventieth birthday at the Sorbonne in 1892. Lister then gave an address as the representative of the Royal Societies of London and of Edinburgh, and, when he had ended, Pasteur's impulsive embrace of Lister touched the hearts of those who were present, as its relation appealed to the imagination of the world when it read of it next day. Many years afterwards Lister, writing on the occasion of the visit of English doctors to Paris in 1905, noted that not only medical men but others "attributed some importance to the incidents of the Pasteur Jubilee; as if they might have acted in some degree as precursors of the *Entente Cordiale*."

WEEKLY HOURS OF WORK.

THE Health of Munition Workers Committee has issued a new memorandum² on weekly hours of employment, supplementing the memorandum on hours of work issued in January, 1916, and modifying some of its recommendations in the light of the exact data yielded by special investigations made for it. As compared with the French, we started with the advantage that the opinion as to the need of a weekly period of rest was practically unanimous, but beyond that there was at the beginning of the war very little agreement. At one extreme were those who defended fifteen hours' work a day, a period worked in peace time to meet temporary trade pressure; at the other were those who advocated only forty-eight hours a week, held that all overtime beyond that was bad, and doubted whether, even when worked to meet urgent demands, the output of a factory was thereby increased. In the absence of scientific data and in view of this conflict of opinion the Committee was cautious. It recommended that the average weekly hours of employment for men should not exceed sixty-five to sixty-seven hours exclusive of meal times; this involved a working day of from thirteen to fourteen hours. For women and girls it recommended a maximum of sixty hours a week, which meant a working day of twelve hours. It advised the same period for boys, and that night work should be limited as far as possible in the case of boys under 16 and of girls under 18. Dr. Vernon's
